Be certain the site you choose has the right growing conditions for fruit trees.

Sunlight. Even one or two hours of daily shade may make fruit smaller and less colorful. Envision the mature size of trees and shrubs close to your planned site. If their shadow will encroach on your fruit trees in years to come, you may want to select a different site, or remove the neighboring plants. Sour cherries tolerate a bit of shade better than other tree fruits do.

Shaded soil in early spring can be beneficial. A cool soil can delay flowering, perhaps until after late killing frosts.

Soil. Fruit trees need well-drained soil. Sandy soils can be too dry to produce a good crop of fruit. Wet, clayey soil encourages various root rots.

Slope. Plant near the top of a gentle slope if possible. Planting on a north-facing slope or about 15 feet from the north side of a building helps slow flowering in spring and protects blossoms from any late frosts. Planting on a south-facing slope can hasten flowering and lead to frost damage. Sheltered alcoves on the south side of a house protect tender trees. Planting in a frost pocket can increase the risk of spring frost damage to flowers and young fruit.

Wind. Blustery winds in open areas or on hilltops can make training difficult, knock fruit off trees early, or topple trees. Staking will help trees resist the force of prevailing winds. Where wind is a problem, you can slow it by erecting a hedge or fence. However, don't box the tree in and stifle the breeze. Air circulation is helpful for reducing diseases.

Spacing. The amount of room your trees will need depends on their mature height and width, how they are trained, their soil fertility level, and tree vigor. Give every tree plenty of space to grow without impinging on neighboring plants or spreading into shady areas. Small trees, such as dwarf peaches and

Continued ➔

nectarines, require only 12 feet between trees, while apple trees need 20 to 30 feet between trees.

Planting. To make the effort and expense of planting fruit trees worthwhile and to maximize yield and fruit quality, it pays to prepare the soil and plant them properly.

Plant fruit trees while dormant in early spring, or in the fall where winters are quite mild. Fall planting gives roots a head start, because they continue to grow until the soil freezes. However, fall planting is risky in areas where the soil freezes, because the low temperatures may kill the newly grown roots.

Words to Know

Standard: A full-sized fruit tree, usually maturing to at least 20 feet in height.

Dwarf and semidwarf: Fruit trees grafted on size-controlling rootstocks. Dwarf trees often mature to 8 to 10 feet in height. Semidwarfs mature to 12 to 18 feet.

Genetic dwarf: A fruit tree that stays quite small without a dwarfing rootstock.

Rootstock: A cultivar onto which a fruiting cultivar is grafted. Rootstocks are selected for strong, healthy roots or for dwarfing effect.

Whip: A young tree, often the first-year growth from a graft or bud.

Scaffolds: The main structural branches on a fruit tree.

Pome fruit: Fruit that has a core containing many seeds, such as apples and pears.

Stone fruit: Fruit with a single hard pit, such as cherries, plums, and peaches.

Low-chill: Requiring fewer hours of cool temperatures to break dormancy.

High-chill: Requiring more hours of cool temperatures to break dormancy.

Self-fruitful: A tree that produces pollen that can pollinate its own flowers.

Compatible cultivars: Cultivars that can successfully cross-pollinate.

Crotch: The angle of emergence of a branch from the tree.

Suckers: Shoots that sprout out of or near the base of a tree.

Watersprouts: Upright shoots that sprout from the trunk and main limbs of a tree.

Most nurseries stock bareroot fruit trees. Plant the young trees as you would any bareroot tree.

You may be able to speed a young tree's establishment by dipping the roots in powdered bonemeal before you plant. Also apply compost tea or manure tea at planting. Allow the tea to sit for several days before applying, or it may burn roots.

Caring for Fruit Trees

You can't, unfortunately, plant fruit trees and sit back and wait for them to produce. Fruit trees need your time and attention throughout the year in order to stay healthy and provide a bumper crop. You'll need to prune and train your trees, fertilize and mulch them, and protect them during the winter. Some trees may require hand-pollinating, while others need to have their fruit thinned. While there are few shortcuts to meeting these important demands, there are right and wrong ways to go about fulfilling them. Knowing the right way will save you time and frustration and give you the best possible fruit yield.

PRUNING AND TRAINING

To grow top-quality fruit, and to have easy access for harvesting, you need to establish a sturdy and efficient branching framework. For home gardens, the two best training methods are open center and central leader. Both systems encourage the growth of branches with wide crotches that are less likely to split when burdened with a heavy fruit load.

It's important to establish the main branches while the tree is young. You'll then maintain tree shape of your bearing trees each year with touch-up pruning. Central leader trees produce more fruiting spurs, important for spur-type apple and pear cultivars. For nectarines, peaches, and Japanese plums, use open center training to maximize air circulation and sunlight penetration among the branches, which will help reduce disease.

Spread young branches so they will develop broad crotch angles. Use clothespins to hold branches out from the trunk, or insert notched boards in the crotch angle. Branches that aren't spread may develop a strip of bark called a bark inclusion in the crotch angle, making the crotch weaker and more likely to break.

In certain circumstances, it's best not to train. Some fruit trees, including apricots and pears, are particularly susceptible to disease, which can invade through pruning cuts or attack young growth that arises near the cuts. If disease is a problem in your area, you may want to limit pruning to general maintenance or renewal of fruiting wood. In the far North, keep training to a minimum, since new growth is more susceptible to winter injury. However, leave some young suckers on main scaffolds to act as renewal wood in case main branches are injured by cold.

Whether you train your trees or not, you should prune off shoots that emerge on the trunk and any branches that cross

and rub. Where one limb grows above and shades another, or when two branches of equal length and diameter arise at one fork, select one branch to keep and prune off the other. During the summer, remove suckers that sprout near the base, watersprouts that shoot out from the trunk or main limbs, and any dead or diseased wood.

When to prune varies with the tree type. You can prune apples and pears in early spring before the trees break dormancy. For stone fruits that are susceptible to cankers caused by disease organisms, wait until bud break, when they are less likely to be infected. Prune away dead and diseased branches on all kinds of fruit trees as the growing season continues. Stop pruning by the end of August in areas where winter injury is a concern. Late pruning can stimulate a flush of new growth that could be damaged when cold weather sets in.

FERTILIZING

Even with thorough advance soil preparation, your fruit trees may need fertilizing. Nutrient consumption varies with tree type and age, soil, and growing conditions. For instance, you will have to fertilize a fruit tree growing in the lawn more frequently than if the soil around the tree is cleared and mulched. But don't simply fertilize on a set schedule. Overfertilizing can encourage soft new growth that is susceptible to disease attack and winter injury.

Monitor tree growth to determine when trees need fertilizing. Nonbearing apple trees should grow 1½ to 2 feet per year; those producing fruit average 8 to 12 inches. Mature peach trees should grow 1 to 1½ feet each year. If your trees seem to be lagging, have the nutrient levels in the leaves analyzed. Call your local extension office for information about leaf analysis.

Fertilize only in the spring. Spread materials on the soil surface in a circle around the trunk out to the edge of the leaf canopy. If the tree is growing in the lawn, make holes with a crowbar around the perimeter of the branches and drop fertilizer below the grass roots. Avoid high-nitrogen fertilizers. The best fertilizer for fruit trees is compost because it has a good balance of nutrients. Foliar seaweed sprays improve tree health, increase yields, and increase bud frost resistance. Spray trees when buds start to show color, when petals drop, and when fruit is ½ to 1 inch.

MULCHING

Mulched trees will have access to more water and nutrients, especially if you use soil-enriching mulch such as compost or shredded leaves. Mulch also will keep down weeds that compete with trees for water and nutrients. It prevents excessive evaporation of soil moisture, a necessity around young or weak trees, in dry climates, and in sandy soils. In areas with fluctuating winter temperatures, mulch will eliminate damage from frost heaving. Mulch can keep the soil cooler in spring and delay flowering of early-spring bloomers such as apricots or peaches, hopefully beyond the threat of frost.

The drawback of mulching is that it can make heavy soils too wet and can harbor pests, especially mice and voles.

Where mulch is warranted, apply a 3- to 6-inch layer of organic mulch in an area from 1 to 2 feet away from the trunk out to just beyond the branch tips. Fluff the mulch with a spading fork occasionally so it doesn't compact. Check the soil moisture level occasionally. If the soil is staying overly wet, rake the mulch back to prevent root rot. You also may want to push the mulch out from under the tree boughs during leaf fall if disease is a problem. Afterward, rake up the fallen leaves and respread the mulch.

WATERING

Ideally, the soil around fruit trees should be evenly moist, neither dry nor waterlogged. Moisture is especially important to young trees and to trees bearing ripening crops. Thoroughly soak the root system of newly planted trees, and repeat whenever the soil becomes dry for the next few months.

After the tree is growing well, your watering schedule will depend on the weather and climate. If the weather has been dry, even during a midwinter warm spell, stick your little finger down in the soil around the drip line. If you do not feel moisture below the surface, water the tree thoroughly. A trickle irrigation system is ideal for watering fruit trees. In cold climates, stop watering by early fall to harden the plant for winter.

WINTER PROTECTION

Protect your trees against winter sunscald, frost heaving, and pest damage, all of which can injure or kill fruit trees. Sunscald occurs when sun-warmed wood is killed by nighttime cold. The damaged area becomes dry, sunken, and attractive to borers and diseases. Prevent sunscald by wrapping the tree trunk with a white plastic tree guard or painting it up to the first (lowest) scaffold branch with white latex paint diluted 1:1 with water.

To minimize frost heaving—shifting of soil when it freezes and thaws—mulch after the soil freezes to keep it frozen. This is especially important for young trees, which can suffer extensive root damage due to frost heaving.

FLOWER AND FRUIT CARE

Once your trees reach maturity, there are some extra activities involved in their seasonal care. Some trees may require hand-pollinating, others may need young fruit thinned, and all will have to be harvested.

Hand-Pollinating. Early-flowering fruit trees can suffer partial to full crop loss if the weather is not mild when the tree is in bloom. If temperatures aren't high enough for insect activity, flowers won't be pollinated and fruit won't develop. If there's a cold spell when your trees are blooming, you can save your crop

Restoring Old Trees

If a fruit goes without regular care, it will become overgrown, minimally productive, and home to hoards of pests and diseases. Should you save the old tree or start over with a new one? If the tree has a lovely shape, vital position in your landscape, or sentimental value, it may be worth keeping. Here's how to restore it:

- If the tree is suffering from diseases such as scab, black knot, or fire blight, begin a spray program to help lessen damage.
- Remove dead and diseased branches.
- Check for trunk or root rot and, in warm climates, nematodes.
- Prune back any neighboring trees and shrubs that shade the fruit tree.
- Take a leaf analysis for nutrient levels, and correct soil nutrient deficiencies. Use a foliar seaweed spray to restore tree vigor while the soil comes back into balance.
- When the tree is reasonably healthy, you can begin to prune it into a productive shape. Gradually thin out unproductive branches to open the canopy to sunlight. To minimize watersprout and sucker regeneration, take no more than one-fourth to one-third of the new wood on the tree or on a particular branch any year.

by hand-pollinating. Simply collect pollen from one tree by rubbing flowers gently with an artist's brush or cotton swab, and then brush the pollen onto the flowers of a compatible cultivar.

Be sure nights are frost-free if you plan to hand-pollinate. If you expect a late frost, you can cover small trees with plastic or spray them with a frost-protecting product. As a last resort, try sprinkling water on trees all night. Use care, as the weight of ice that forms on the trees can break branches.

Thinning. Because fruit trees tend to be overburdened by young fruit, you should thin off the excess on all trees except those with cherry-size fruit. Without your intervention, the weight of the fruit may actually break limbs. The stress from the excessive fruit load may also reduce the number of flower buds the tree produces the nest year. Disease problems such as brown rot can spread quickly among crowded fruits, ruining the crop before it ripens. In addition to avoiding problems, thinning lets you channel all the tree's resources into fewer but bigger and more beautiful fruit.

Thin when the fruit is young—the smaller the better. First clip or twist off all insect-damaged or deformed fruits. Then remove the smaller fruits. Leave only the biggest and best.

If you can't reach the upper limbs of large trees, tap the limbs with a padded pole to shake loose some of the extras. On small apple, nectarine, and peach trees with big fruit, thin fruit to 6 to 8 inches apart. Plums and apricots can be more closely spaced, about 3 to 5 inches apart.

Even after thinning, fruit may become heavy enough to tèar a branch. For extra support, prop branches up with a forked stick. On central leader trees, you can secure branches to the central leader with a rope or with a chain covered with garden hose.

Harvesting. Most fruit is ready to harvest when the green undercolor changes to yellow or the fruit softens and drops. Grasp the fruit in the palm of your hand and twist it off the stem carefully so you don't damage the branch. Handle the ripe fruit gently so it does not bruise.

PESTS AND DISEASES

It's not easy to grow fruit trees using only organic pest control methods. Fruit is so succulent and tasty that it attracts a wide range of pests, from mites to deer. Watch your trees diligently for pests, and control them before they damage the tree or the fruit.

Growing Fruits and Berries

Planting Fruit Trees

Fruit trees are an investment that can yield bountiful, delicious interest for many years after planting. To get the best return on your investment, it's important to take extra care in selecting the right plants and picking the best site for them. There are many types of tree fruits from which to choose, and the best choices for you will depend on where you live and how much space you have available. Your local cooperative extension agent also may be able to recommend cultivars suitable for your area.

Just because you have limited space in your garden doesn't mean you can't enjoy the taste of fresh, tree-ripened fruit. Many tree fruits are grafted onto rootstocks that affect their size at maturity, and the availability of dwarf or semidwarf trees makes it possible to grow a bearing-size tree in even the smallest garden. Even if you have plenty of room available, dwarf and semidwarf plants have other advantages. Their fruit is easy to reach for picking, and it's generally easier to prune and care for smaller trees. Finally, dwarf and semidwarf fruit trees begin blooming and bear fruit sooner than standards.

SITE SELECTION

It's important to select the best possible site for your trees. For best yields, fruit trees need full sun. Avoid areas in the shadow of large ornamental trees or tall buildings. Most fruit trees prefer deep, loamy soil that is moist but well-drained and rich

in organic matter, although they'll tolerate many types of soils. Heavy clay soils, however, will impede root system formation and result in poor tree growth. If you have clayey soil, plan on adding plenty of organic matter to a large area around the planting site and working it in as deeply as possible. Or consider making a large raised bed to accommodate one or several dwarf fruit trees.

Look for a site that offers good air drainage. Cold air drains downhill and settles in valleys or against barriers such as thick hedges, creating frost pockets. Frost can damage fruit blossoms, which appear in early spring, so try to plant trees near the top of a slope rather than at the bottom where chilly air often collects. A south- or southeast-facing slope is fine, although very early blooming trees sometimes are best planted on the side of a north-facing slope. This helps delay bloom and increases the likelihood that tender flowers will survive spring frosts. Although trees should be protected from strong prevailing winds, they should be planted in a site with good air circulation.

Heeling-In

You can buy container-grown fruit trees or field-grown trees dug and sold with their roots wrapped in burlap (called balled-and-burlapped or "b & b"). Fruit trees also are commonly sold bare-root, that is, with all the soil removed from the root system and with the roots packed in wood shavings or similar material.

It's best if you have the site all prepared so you can plant your fruit trees as soon as you bring them home or they arrive in the mail. However, if that's not possible, both container-grown and balled-and-burlapped trees can be set in a sheltered site out of sun and wind and watered regularly until you find time to plant. Bare-root trees, on the other hand, need immediate attention to keep the roots from drying out. If you can't plant them right away, you'll need to protect them with a technique known as heeling-in.

Soak the roots of bare-root trees in water for an hour or so before heeling them in. Then find a spot sheltered from direct wind and sun (the north-facing wall of a house can provide good shelter) and dig a trench with one sloping side, large enough to accommodate the roots. Lean the trees against the angled side with their roots in the trench and cover the roots with soil (or a combination of peat moss and soil), pressing lightly to pack the soil around the roots. Water thoroughly and keep the roots evenly moist but not wet until you can move the trees to their permanent location.

If your soil is frozen or too wet for heeling plants into a trench, you can use a large pot, plastic bucket, or heavy plastic garbage bag to hold moist potting soil or peat moss around the roots. Keep trees in such makeshift containers in a cool (40° to 45°F), humid garage, shed, or basement, or in a shaded outdoor area if the temperature is above freezing. If you use garbage bags, be sure to leave the top open so the roots have an air supply. Lightly water the peat moss or soil when it dries out.

It may seem reasonable to just put your new tree in a tub or pail of water. But roots can't breathe underwater and can be damaged if left this way for more than 24 hours. However, this method is fine for temporary storage overnight or for keeping the tree roots moist while you are preparing the planting hole.

Whatever method you use, remember that heeling-in is a temporary measure only. Try to move your trees to their permanent site as soon as possible.

PLANTING POINTERS

One of the best things you can do for your new fruit trees is to have the planting site ready and waiting for them. This minimizes transplant stress and helps get them off to a good start.

Site Preparation

Dig a hole that is at least 3 feet in diameter and 1½ to 2 feet deep. When in doubt, dig as wide a hole as you can, to encourage roots to spread out laterally in every direction. Remove any large rocks. Rough up the sides of the hole after you've finished digging, to eliminate hard-packed sides that may be impenetrable to roots.

In the past, amending the soil removed from the hole with compost, purchased topsoil, or peat was considered standard operating procedure. However, recent observations indicate that filling the planting hole with rich, amended soil encouraged the roots to remain within the planting hole rather than work their way out and down into the surrounding soil. Although you may want to test the pH of your soil and adjust accordingly, or add a cup of bonemeal in the bottom of the hole, plan on filling with unamended, native soil.

Spring or Fall?

True or false. The best time to plant fruit trees is in the spring. **The answer:** It depends where you live. In areas where cold weather arrives in early autumn and temperatures often fall below -10°F, planting in the early spring will give the young tree time to grow and harden before the onset of harsh winter temperatures. Spring rains will help keep newly planted trees well watered for proper growth.

However, if your local conditions include hot, dry summers and mild winters, fall planting can give a new tree extra time to establish a healthy root system that can survive harsh summer weather. Because the tree is planted while dormant, the roots have time to become established before buds break in the spring. Fall-planted trees have a further advantage of being able to begin growth in early spring, when soil is still too wet for tree planting. Also, the soil in the fall is often drier and easier to work. For the best root growth and winter survival, fall planting should only be done in those areas where the soil temperature remains above 50°F several weeks after the trees become dormant. Plant as early in the fall as you can to take advantage of good root-growing weather.

Continued →

Determining the Proper Depth

Before you plant, examine the trunk close to the roots. If your plant has been grafted, you'll find a slight knob or crook near the base of the stem. This is the graft union. Dwarf and semidwarf trees should be planted with the graft union aboveground. Covering the graft union would allow the upper part of the tree, called the scion, to root, and you would lose the effect of the dwarfing rootstock. If you live in an area with high winds, plant the tree with the top part of the graft union knob toward the prevailing wind.

Plant standard trees so the graft union is 1 to 2 inches below the ground. (Since in this case you're not worried about keeping the plant small, it doesn't matter if the scion produces its own roots.) This provides protection from severe winter weather and gives the tree better anchorage.

To see if your tree will be at the proper depth, place it in the hole you have prepared and set a broomstick or pole across the hole to help judge the depth. Make a pyramid- or cone-shaped mound of soil in the center to spread out the roots of bare-root trees. Set container-grown or balled-and-burlapped trees in the hole, container and all. If the tree is too low, add more soil to the central mound, and remove some soil if the tree is too high.

Planting

At planting time, remove containers completely—even peat or papier-mâché ones—and check to make sure that the roots aren't circling around the root ball. For balled-and-burlapped trees, cut the burlap in several places to make it easy for the roots to grow out into the surrounding soil; remove any string or wire holding the burlap in place, along with synthetic fabrics sometimes used as burlap substitutes. Cut back any broken or damaged roots without disturbing the root ball.

Soak the roots of bare-root trees for an hour or so before planting. Then cut ½ inch off broken root tips so that healthy tissue will contact the soil and more fine roots will be stimulated to grow. Prune crushed or broken roots.

If you are planting more than one fruit tree, space dwarf fruit trees 8 to 15 feet apart; semidwarf trees, 10 to 12 feet; standard trees, 25 feet. Use the larger spacing for the dwarf or semidwarf trees if your soil is deep and fertile, as each tree's root system will expand more through the years in these soils.

It's easiest to have another person hold the tree in the right position as you start to fill in the soil. Have him or her gently shake the tree as you shovel, to help settle soil around the roots. When the roots are covered by several inches of soil, you can start to press the soil down with your hands. Do this gently, taking care not to break any roots. When the hole is two-thirds filled, soak the site with a pail of water to help settle the soil around the roots. Then finish adding soil to ground level. Press the soil so that there is a bowl-shaped indentation in the ground—this will help hold water during the first growing season—and water thoroughly.

Pruning at Planting Time

It may seem criminal to cut branches off your newly purchased fruit trees, but selected pruning will ultimately lead to better tree form and growth. You'll need to remove any dead branches, which will look shriveled and blackened at planting time. If you're not sure whether a branch has life in it, carefully scrape away a small piece of bark with your fingernail. Dead wood is brown, gray, or black; healthy wood is green.

In the past, the general recommendation was to cut back unbranched bare-root trees by approximately one-third or one-half at planting time. This was thought to balance the loss of roots that occurred when the tree was dug at the nursery. Research indicates this is not necessary: Do not prune unbranched bare-root trees at planting time.

The only pruning that branched specimens need at planting time is to establish the basic framework of the tree. Remove any damaged or dead branches, along with branches growing vertically (or nearly so) against the main trunk. The narrow crotches these branches create are weak and tend to break under heavy fruit loads. The strongest branch angles are 45 degrees or greater. Choose three to five branches that are evenly spaced around the circumference of the central leader and have wide crotch angles. These will become the scaffold branches or the main branches of the tree. Prune out all the other branches.

FINISHING UP

Here are a few final steps to settle your fruit trees into their new home.

1. Cut off any wire tags to prevent them from cutting into the tree as it grows.
2. Stake the trunks of newly planted trees. (Fruit trees grafted on dwarf rootstocks will require permanent staking.) For best support, use three stakes placed as a triangle about a foot away from the trunk. Thread a sturdy wire through an old piece of rubber hose, loop the rubber hose portion around the trunk, and attach the ends of the wire to one stake. Do the same thing for the other two stakes.
3. Wrap a spiral plastic tree guard around the tree trunk to protect it from gnawing animals and winter sunscald.
4. For spring-planted trees, place a 6-inch layer of compost, straw or other organic mulch around the tree to prevent weeds and help conserve soil moisture. In the fall, move the mulch away from the trunk, as it makes a good nesting and hiding place for mice.

Pollination and Fruit Set

Blooming fruit trees are a beautiful feature of the spring landscape, but, surprisingly, plenty of flowers doesn't always mean a plentiful harvest. Before your trees' flowers can bear fruit, they need to be pollinated and have an adequate fruit set. There are a

Selecting Tree Fruits

Fruit trees are ornamental as well as useful, and homegrown fruit, whether eaten fresh, baked in pies, or preserved in jelly is a special treat. Before buying a tree, check with your local cooperative extension agent to find out what cultivars are best for your area. Consider planting some of the many disease-resistant cultivars available. Yields listed are for 1 year.

Fruit	Yield per Plant	Culture	Harvest Information	Comments
Apple (*Malus pumila*)	Standard: 10–20 bu. Semidwarf: 5-10 bu. Dwarf: 1–5 bu.	Full sun. Average, well-drained soil rich in organic matter; pH 5.5–7.0. Buy 1- or 2-year-old trees. Site should be protected from frost; the middle of a gentle, south-facing slope is ideal. Allow as much space between trees as their height at maturity. Water and mulch around young trees, but do not mulch near trunk. Zones 3–8.	Dwarf trees will fruit in 2–4 years after planting; semidwarfs, in 3–5 years; standards, in 5–7 years. Different cultivars ripen from early to late summer or early fall. Pick fruit when ripe but firm. Hold apple and stem and twist gently, while tilting upwards. Keep stems on apples. Do not damage spurs when harvesting.	Most apples sold today are grafted on root-stocks that affect growth rate; dwarf, semi-dwarf, and standard-size trees are available in most cultivars. Dwarf trees grow to be 8–12 ft.; semidwarf, 12–20 ft.; and standards, 20–40 ft. May live up to 35 years; some may fruit heavily every other year. Some cultivars are self-sterile (2 cultivars needed for pollination); others, partially self-fertile. Disease-resistant cultivars include 'Freedom,' 'Liberty,' 'Macfree,' 'Nova Easygro,' 'Prima,' 'Priscilla,' and 'Redfree.'
Apricot (*Prunus armeniaca*)	Standard: 3–4 bu. Dwarf: 3 bu.	Full sun. Deep, average, loamy soil that is moist but well drained; pH 6.0–7.0. Buy 3–5 ft., 1-year-old plants. Plant on a north-facing slope protected from cold winds if possible. Allow at least as much space between trees as their height at maturity. Avoid planting near or after member of the nightshade family, brambles, or strawberries. Prune out nonfruiting spurs. Zones 4–9.	Will fruit in 3–5 years. Fruits ripen in late summer. Harvest when fruit is almost firm and orange-yellow all over. Hold fruit and gently twist while tilting upwards.	Apricots are fast growing and may live up to 35 years. Standard trees grow 15–25 ft. high; dwarf (grafted) trees, 8–12 ft. Most are self-fertile, although a few cultivars, such as 'Moongold' and 'Sungold,' should be planted together for pollination. Thin to even out annual yield. Pink flowers open in early spring but are often ruined by frost. Disease-resistant cultivars include 'Harcot,' 'Harlayne,' and 'Harogem.'
Cherry (*Prunus* spp.)	Standard, sweet: 3–6 bu. Standard, sour: 2–5 bu. Dwarf (genetic): up to 1 bu.	Full sun. Light, moist, well-drained soil rich in organic matter; pH 6.0–8.0. Buy 1- or 2-year-old trees. A north-facing slope protected from cold winds will help delay bloom and prevent frost damage to buds. Allow as much space between plants as their height at maturity. Sweet cherries grow in Zones 5–8; sour cherries, Zones 4–8.	Sweet cherries will fruit in 3–6 years; sours in 3–5 years. Sweet cherries ripen in early summer; sour ones ripen a little later. Harvest when cherries have full color by gently twisting stems upward off of spur; ripe sour cherries are easily pulled from pits (which remain on stem).	Cherry trees may live 30–40 years. Sour cherries are self-fertile. Sweet cherries usually require compatible cultivars with overlapping blooming periods for pollination. Dwarf trees reach 6–15 ft. Standard sweet cherries grow to 20–40 ft.; sour cherries, 15–25 ft. Sour cherries are smaller than sweet ones and used for cooking. Disease-resistant cultivars include 'Hedelfingen' (sweet), 'North Star' (sour), 'Sam' (sweet), and 'Windsor' (sweet).
Citrus (*Citrus* spp.)	Depends on fruit, tree size, and conditions. True citrus can range from 150–1,000 lbs. Kumquats: 40 lbs.	Full sun. Light, loamy, moist but well-drained soil rich in organic matter; pH 5.0–7.0. Buy 1-year-old, certified disease-free trees. Planting is best done in late winter or early spring. Choose a warm, sunny, sheltered area. Space 15–35 ft. apart. Protect young trees from sunburn and cold. Water deeply and often. Require high nitrogen. Zones 9–10.	Will fruit in 3–6 years. Harvest when fruit is fully ripened, which is indicated by its mature size, color, and taste. With shears, cut ripe fruit at point it is attached to stem. Most types will keep well on the tree, so harvest only what you can use.	Includes lime, lemon, grapefruit, orange, tangerine, and kumquat. Trees grow from 5–50 ft.; may fruit up to 100 years. Citrus trees will not grow well at temperatures below 55°F. Fruits take 7–14 months to ripen. Recommended cultivars include grapefruits 'Marsh Seedless,' 'Redblush,' and 'Rio Red'; blood oranges 'Moro,' 'Sanguinella,' and 'Tarocco'; kumquats 'Meiwa' and 'Nagami'; lemons 'Eureka' and 'Meyer'; limes 'Bearss' and 'Persian'; tangerines 'Dancy,' 'Page,' and 'Satsuma'; oranges 'Pineapple,' 'Valencia,' and 'Washington Navel.'

Continued →

Peach and Nectarine (*Prunus persica*)	Standard: 2–5 bu. Dwarf (grafted): 2–3 bu.	Full sun. Loamy or sandy soil that is moist but well drained and rich in organic matter; pH 6.0–7.0. Buy 3–5 ft., 1-year-old trees. Plant on a southern slope unless spring temperatures fluctuate widely. If so, choose a north-facing slope. Allow 15–25 ft. between trees. Zones 4–10.	Will fruit in 1–3 years. Harvest fruit in mid- to late summer when it is fairly firm and no green visible; should twist off limb without much effort.	May live 10–20 years. Standard trees grow from 8–20 ft.; dwarf trees, 6–10 ft. Both come in freestone (flesh separates easily from pit) or clingstone (flesh clings to pit) cultivars. Disease-resistant cultivars include peaches 'Clayton,' 'Newhaven,' and 'Red-haven'; nectarines 'Mericrest' and 'Redchief.'
Pear (*Pyrus communis*)	Standard: 5–10 bu. Dwarf (grafted): ½–2 bu.	Full sun to partial shade. Deep, loamy soil that is moist but well drained; pH 6.0–7.0. Buy a 4–6 ft. standard, or 2½–4 ft. dwarf, 1- or 2-year-old trees. Select a site protected from harsh winds but with good air circulation. Allow 16–25 ft. between standards; 12–15 ft. between dwarfs. Zones 2–10.	Standard trees will fruit in 4–6 years; dwarfs in 2–4 years. Fruits ripen in late summer to early fall. Harvest pears when stems swell near twigs, the green skin lightens or starts to turn yellow, and they are easily separated from the twig. Fruit ripened on tree will develop brown centers and grainy texture.	Early and late-ripening cultivars available. Standard trees reach 15–25 ft.; dwarf (grafted) trees, only 8–15 ft. May live 50–75 years. Most require another cultivar for pollination; some are incompatible. Disease-resistant cultivars include 'Kieffer,' 'Monterrey,' 'Orient,' and 'Seckel.'
Persimmon (*Diospyros virginiana, D. kaki*)	50–100 lbs.	Full sun to partial shade. Well-drained soil; pH 6.0–7.0. Buy 1- or 2-year-old trees. A southern exposure is best. Space 18–20 ft. Mulch thickly. American, Zones 4–8; Japanese, Zones 7–10.	Will fruit in 3–4 years. Fruit ripens in fall. Pick when still a bit firm, keeping stem on fruit, and let ripen in warm room. Most persimmons are astringent and can only be eaten when soft. Ripe persimmons are very sweet and can be eaten fresh, dried, or used in pastries.	May live 50 years or more. American cultivars grow to 30–60 ft.; Japanese types to 20–40 ft. Most American cultivars require a pollinator; Japanese are usually self-fertile. American persimmon has yellow-orange or purple fruit, 1–2 in. wide; Japanese are orange to bright yellow, 1½–4 in. wide. Recommended American cultivars include 'Early Golden,' 'Garretson,' and 'Meader'; Japanese persimmons 'Fuyu,' 'Hachiya,' and 'Tanenashi.'
Plum (*Prunus* spp.)	Standard: 1–3 bu. Dwarf: ½–1 bu.	Full sun. Slightly heavy, moist but well-drained soil rich in organic matter; pH 6.0–8.0. Buy 3–6 ft. standard, or 3–4 ft. dwarf, 1-year-old trees. A north-facing slope will help delay bloom and prevent bud damage from frost. Space trees 18–24 ft. apart. Japanese, Zones 4–9; European, Zones 4–8.	Japanese plums fruit in 2–4 years; European plums fruit in 3–5 years. Fruits ripen in midsummer. Harvest plums when they develop a waxy white coating ("bloom"). Pick soft for eating fresh or drying, or fairly firm for cooking.	Standard plum trees reach 15–20 ft.; dwarf trees grow 8–15 ft. Japanese plums are 2–3 in. wide and usually red or yellow; European plums, 1–2 in. wide, and usually blue or purple. Plums bear fruit 25–30 years. Cultivars may require others from the same family for successful pollination. Disease-resistant cultivars include Japanese plums 'Crimson' and 'Starking Delicious'; European plums 'Count Althann's Gage,' 'Oneida,' and 'President.'

number of factors that can stand in the way. Fickle spring weather is one of them; pollen compatibility, another. Fortunately, there are some steps you can take to ensure a bountiful crop.

FROM FLOWERS TO FRUITS

To understand the fruiting process, you'll need to know a little basic botany. Nearly everyone can identify the petals of an apple or peach blossom. Just inside the petals are a circle of slender filaments with yellow dust on top. These are the stamens, the male flower part, topped with pollen. The stamens surround the pistil, the female part of the flower. If you pull off the petals and some of the stamens, you can see the structure of the pistil. The sticky tip of the pistol, which collects the pollen, is called the stigma. The swollen part at the bottom is the ovary, which is connected to the stigma by a narrow stalk called the style. The ovary contains the eggs and develops into the fruit.

When a pollen grain lands on the stigma, it germinates and produces a long tube that grows down through the style into the ovary. This tube carries two sperm cells: One fuses with the egg to eventually form the seedling, the other fuses with a cell to form nutrient tissue for the seedling. Both must fuse, or no seed or fruit will form. In apples and pears, each ovary has ten eggs; ovaries of other fruit flowers have fewer eggs. Fruit size is linked to the number of seeds that mature, because developing seeds produce a hormone that signals the fleshy part of the fruit to enlarge.

Pollination Requirements of Fruit Trees

There are a few basic principles to keep in mind when considering pollination requirements of fruit trees. Trees can be self-unfruitful or self-sterile, meaning they can pollinate the blooms of other trees but require pollen from another cultivar to set fruit. They can be sterile, meaning they can't pollinate their own flowers or those of any other trees. Cultivars can also be incompatible, meaning they cannot pollinate each other's blooms. Some cultivars have several different forms with different names that won't pollinate each other. For example, 'Starkspur Golden Delicious' apple won't pollinate 'Golden Delicious.' Don't be fooled by dwarfing rootstocks, either; if a cultivar is self-unfruitful, a dwarf tree won't pollinate a standard tree of that cultivar.

When selecting a pollinator cultivar, you'll need to make certain that it blooms at about the same time as the tree you want to have pollinated—a late-blooming cultivar can't pollinate an early-blooming one. You'll need to plant the trees close enough for proper pollination. Your local nursery owner, cooperative extension agent, or mail-order source will have information on bloom time and compatibility of various cultivars.

Apples
Some apples are self-fertile, although most have better fruit set if pollinated by another cultivar. Trees must be no more than 80 feet apart for pollination. Crabapples can be used to pollinate apples. 'Gravenstein,' 'Mutsu' (also called 'Crispin'), 'Jonagold,' and 'Winesap' are sterile. 'Golden Delicious,' 'Jonathan,' and 'Yellow Transparent' are self-pollinating but yield more if cross-pollinated. 'Granny Smith' and 'Tydeman Red' are incompatible and are poor self-pollinators.

Apricots
Most are self-fertile. 'Early Golden,' 'Chinese,' and 'Moorpark' are self-fertile but will produce a better crop if cross-pollinated. A few cultivars including 'Goldrich' and 'Perfection' need cross-pollination.

Cherries
Most sweet cherry cultivars require cross-pollination for best crops; sour cherries do not require cross-pollination but set heavier crops if crossed. Trees must be no more than 40 yards apart for pollination. Sour cherries aren't good pollinators for sweet cherries because they bloom later. Sweet cherries 'Bing,' 'Emperor Francis,' 'Lambert,' and 'Napoleon' (also called 'Royal Ann') are self-unfruitful and will not pollinate each other. 'Stella' and 'Lapins' are both self-fertile.

Peaches and Nectarines
Most cultivars are self-fertile. Peaches 'J. H. Hale,' 'Erlihale,' 'Indian Free,' and 'White Hale' are sterile.

Pears
Common pear cultivars need cross-pollination for best fruit set. Asian pears also require cross-pollination and will cross with common pear cultivars. Trees must be no more than 150 feet apart for pollination. 'Magness' is sterile. 'Bedford,' 'Bristol Cross,' and 'Waite' produce little pollen. 'Max Red' is a type of 'Bartlett' and won't pollinate 'Bartlett.' 'Bartlett' and 'Seckel' are incompatible.

Plums
Many European plums (and cultivars sold as prunes) are self-fruitful, although most will produce better crops if cross-pollinated. Japanese plums need cross-pollination. Japanese and European cultivars will not cross-pollinate each other.

OF WEATHER AND BUGS

All of our common fruit trees need bees or other insects for pollination—to carry pollen from stamens to stigma. However, honeybees don't fly in rainy weather and are sluggish at temperatures below 65°F. Adequate pollination is a problem in wet, cold springs. Furthermore, a spring cold snap with below-freezing temperatures can kill blossoms before bees even have a chance to pollinate them.

Even if the flower is successfully pollinated, weather still can interfere with fertilization. High temperatures can kill the ovary before the pollen tubes deliver the sperm, or cold weather (close to freezing) can delay pollen tube growth so the crucial period for fertilization is missed. In both these cases, there will be little fruit set despite a beautiful spring bloom.

Winter weather can damage fruit flowers in the bud so that they either drop before blooming or bloom but then do not

Continued →

set fruit. (Flower buds can be less hardy than leaf buds, so this can happen even though the tree seems otherwise undamaged.) Extreme cold can cause bud damage, but the most common cause is a winter warm spell followed by freezing temperatures. The tree loses its ability to withstand the cold during the warm spell and then is damaged in the following cold weather.

While you can't do much about the weather, you can make certain not to spray blooming trees with insecticides or other chemicals that kill or harm the all-important pollinators. Even botanical insecticides like pyrethrum and rotenone are deadly to bees; try to avoid spraying altogether or spray at dusk when bees are less active.

POLLEN COMPATIBILITY

Not only must the pollen land on the stigma for pollination to occur, it often must be the right pollen. While the flowers of many fruit tree cultivars can be pollinated by their own pollen, some have defective pollen that either does not germinate at all or simply does not pollinate effectively. Sterile cultivars such as 'Winesap' and 'Stayman' apples require pollen from another cultivar in order to produce fruit and can't pollinate any other trees. Many fruit trees don't pollinate their own flowers effectively; for a bumper harvest, you will need a second cultivar for pollination. But some cultivars are incompatible and cannot cross-pollinate. (See "Pollination Requirements of Fruit Trees" for a guide to common cultivars and compatibility.)

BEATING BLOOMING PROBLEMS

There are a few things you can do when you have only one tree blooming and your pollinator cultivar isn't blooming. If a neighbor or friend has a blooming pollinator cultivar, ask to cut a few flowering branches. Place them in a bucket of water. Hang the bucket in the tree so that the bees will work both the flowers of the cut branches as well as those on the tree.

If there aren't many bees and you only have a few flowers, try hand-pollinating. With a paintbrush, touch the stamens of the flowers to collect pollen. Then brush the pollen onto the stigma of the flower to be pollinated.

Another way to satisfy the need for different pollinating cultivars is to graft a pollinator cultivar onto the tree, creating a two-in-one tree. Many nurseries offer such specially grafted trees, making it easy to grow different cultivars of fruit on one tree.

FRUIT SET AND YIELD

Flower buds of common tree fruits form during the months of August and September of the year before blooming. If the tree lacks adequate nutrients, water, or sunlight during that critical flower development phase, there will be few flowers blooming the following spring. While it is important to provide adequate water during this time, don't feed heavily—growth won't harden adequately before cold winter weather arrives. An early spring feeding—such as a 6-inch layer of compost or well-rotted manures used as mulch—will ensure that your trees are well nourished during the summer yield and flower-development periods.

Fruit trees always produce more flowers than they can possibly ripen as fruit, and some of the developing fruit drops naturally. Generally there are two periods of fruit drop, one soon after the blooming period, and then another within the month. For many cultivars, bearing a heavy crop of fruit one year will draw nutrients away from the developing flower buds, resulting in a light crop the following year. In extreme cases, the tree will develop a pattern of bearing fruit every other year. You can even out your yield by heavily thinning the fruit in the early summer of the "on" year.

Pruning and Training Fruit Trees

After the sometimes back-breaking work of digging planting holes and setting your trees, you may feel tempted to just lean back and watch them grow. But if your goal is healthy, early-bearing, heavy-yielding fruit trees, plan on pruning and training your trees rather than letting nature take its course.

If you think of your fruit tree as a solar collector, it is easy to see that proper spacing of the branches by training and pruning will allow more leaf surface area to face the sun. The more energy the leaves capture, the more flowers, fruit, and vegetative growth the tree will produce. In fact, sun must shine at least 30 percent of the time on fruiting branches or they won't develop flowers. Furthermore, fruits such as apples and cherries need light to develop proper color, which is why fruit borne on interior branches often isn't as highly colored as fruit on outside limbs. Proper training will encourage earlier fruit bearing.

Proper pruning helps control diseases, too. Fruit and foliage on properly spaced branches dry more quickly after rain

Parts of a Fruit Tree

To understand where to prune, you need to know the parts of your fruit tree. The primary scaffold branches arise from the trunk to form the basic framework of the tree. The crotch angle is the angle formed between the primary scaffolds and the trunk. The primary scaffold branches divide into secondary scaffolds. The finer branches of a scaffold are called laterals. Water sprouts, foot suckers, crossing branches, and limbs that shade or rub against one another should be pruned away annually, along with diseased and damaged limbs. Also try to remove or train branches with narrow, weak crotch angles.

or in humid weather, thus reducing the spread of fungal diseases that can ruin the ripening fruit as well as the tree. Thus, pruning and training can eliminate the need for expensive and time-consuming disease control.

Finally, pruning and training keep the tree small enough for easy harvests. Some fruit trees, particularly cherries, can become so large that, without proper care, much of the fruit becomes inaccessible. Fruit trees should be shaped to fit in with the scale of your landscaping.

For young trees, the only pruning tool you may need is a good pair of hand pruners. These cut small branches (up to ½-inch diameter) cleanly. As your tree grows and increases in diameter, you will need lopping shears, which make clean cuts through branches of up to 1¼ inches in diameter, and a pruning saw for larger branches.

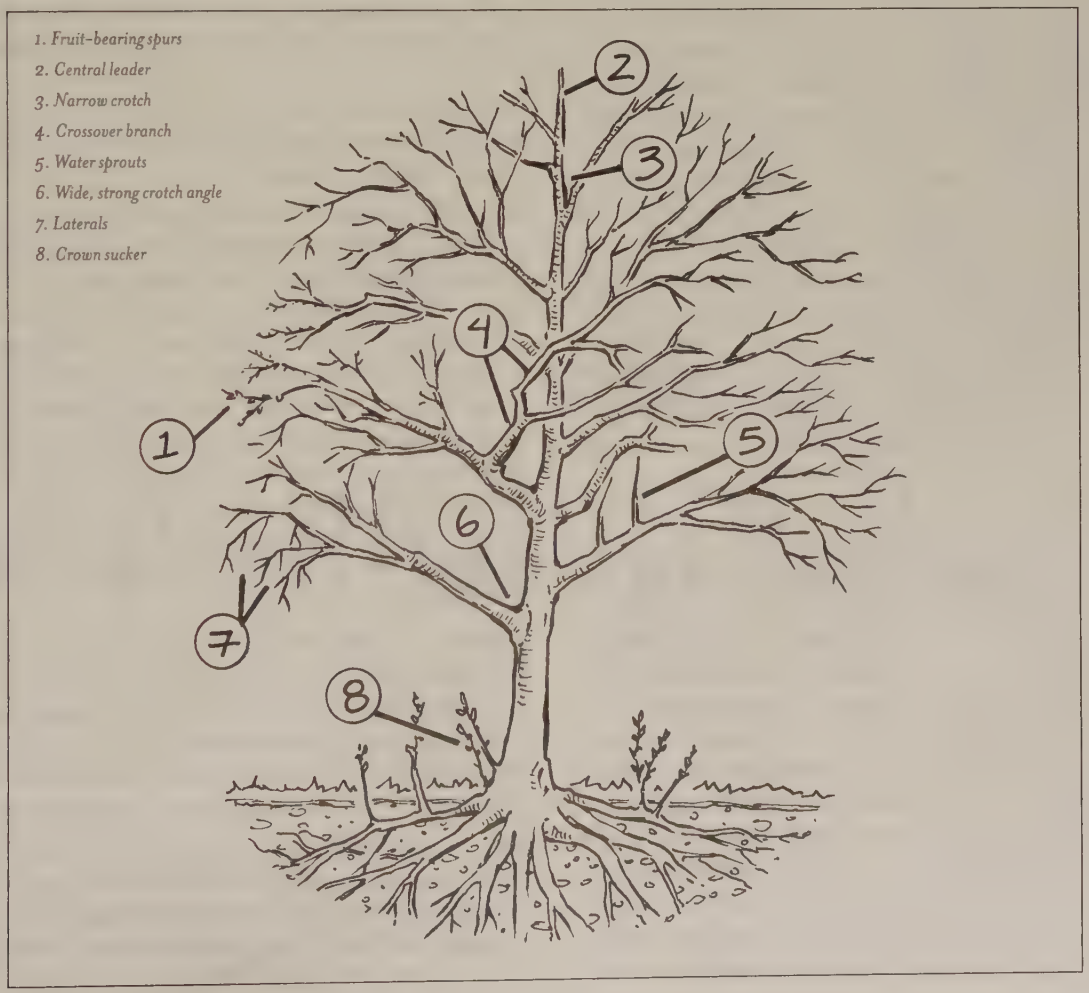
It is important to clean your equipment by dipping it in a 10 percent bleach solution once you finish pruning a tree. Dip between cuts when trimming away diseased wood to prevent the spread of disease.

BASIC TECHNIQUES

The basic principles for pruning fruit trees don't differ much from those that apply to pruning ornamental trees. Proper pruning improves and promotes the health, vigor, productivity, safety, and appearance of a tree—ornamental or fruit. However, with fruit trees there are some special concerns that affect pruning and training. Fruit trees must be able to withstand the weight of heavy fruit loads. Maximum exposure to sunlight is important for fruit production and ripening.

Pruning for Strength and Yield

It's important to prune and train fruit trees so they will be able to withstand the often considerable weight of ripening fruit. Many fruit trees have branches that grow almost vertically up from the trunk, creating narrow crotches or branch angles that are more likely to break when bearing a heavy fruit crop. These branches are also more likely to break during storms. Wide branch angles—45 to 90 degrees—are the strongest, and are the goal of all pruning and training techniques. (See "Parts of a Fruit Tree" below for more on the basic structure of a tree.)



Continued

Branch angle also affects fruit yield. Besides having a poor shape for sun-gathering, these narrow-crotched branches will be very slow to bear fruit. Branches growing at a 45- to 60-degree angle will develop more flowers and fruit.

Before you prune, it's important to know how the fruit tree bears its fruit. Many trees bear their flowers on spurs, short stubby branches that grow from the secondary scaffolds. Spurs can bear for as many as 5 to 20 years, as they do in apples, pears, European prunes, Japanese plums, and sweet cherries. Or they may bear only a few years, as in apricots and sour cherries. Try not to break off or remove spurs; the tree will have to develop new ones before fruiting again. Peaches, nectarines, apricots, Japanese plums, European prunes, and sour cherries fruit on lateral buds borne on the previous season's growth. These trees need annual pruning to ensure a constant supply of second-year wood. These plants also need pruning to keep the fruit within reach for picking and not so far out on the branches that it causes them to break under the fruit load.

Types of Cuts

There are two basic types of cuts you can make: thinning cuts and heading cuts. A thinning cut completely removes a branch, allowing sunlight to reach the center of the plant and directing energy toward the remaining branches. You can thin primary scaffold branches, which arise at the trunk, or secondary scaffold branches, which originate on the primary branches. Thinning cuts should be made at the base of the branch, but without removing the branch collar, the thickened area at the base of the branch.

Heading cuts are made in the middle of a branch to encourage branching and thicker, fuller growth. Cut just above a bud that points in the direction you want growth to occur. Don't cut straight across the branch; instead, cut at about a 45-degree angle across the branch, sloping away from the bud. The top of the cut should be ½ inch above the top of the bud; the bottom of the cut should be at a point above and on the opposite side of the branch from the base of the bud.

Spreading

Spreading is a training technique that is very helpful for strengthening branches by increasing narrow crotch angles. Spreading is most successful when the branch is young and supple—newly sprouted or no more than one to two years old. One of the easiest methods is to clip a clothespin between the trunk and the limb so the limb is pushed into the proper position. Another method is to cut notches in a lightweight piece of wood and wedge it between the limb and trunk. Hanging a fishing weight on the young limb until it bends to the proper position is also effective. Once the limb has grown and stays naturally in the new position, remove the spreading device.

If you need to spread a limb that is older but still can be easily bent into position, tie fabric loops around the limb and then tie a light rope to each loop. Pound a stake into the ground so that when the rope is tied to the stake, the limb is bent into position. If they can be spared, it is best to remove limbs that can't be bent easily into position.

Seasonal Considerations

A tree's response to pruning depends on the season. Late winter or early spring pruning—while trees are dormant—encourages vigorous growth, because food stored for spring growth will be shared by fewer growing points. Most fruit trees need annual dormant season pruning, though in some cases it will be only to remove any dead or broken branches. It is best to wait until just before spring growth to prune most trees. This makes the tree more resistant to winter injury and eliminates the need to reprune when a late winter storm damages or kills branches. Recent research indicates that peaches, nectarines, and apricots present an exception to this rule: Pruning them before they have finished flowering leaves them open to canker, which can invade pruning wounds. Prune these trees after they have finished flowering.

Pruning in early or midsummer results in less vigorous growth, because the stored food has already been used up by growing leaves and shoots. This is why trees trained as espaliers are often pruned in summer—to discourage vegetative growth.

Annual Pruning

To maintain healthy and fruitful trees, there are a few basic things to look for each year.

Dead or Broken Branches. The first step in pruning or training is to remove any dead or broken branches. It's easy to pick out a dead branch on a green tree, but when that same tree is dormant, live and dead wood is hard to distinguish. Dead branches are often withered or very dark when compared to living branches. An easy trick to use when dormant pruning is to start at the tip of a branch or year-old shoot, and carefully scrape a small area on the surface of the branch—it should be green just under the thin bark at the tip of the shoot. If it is black, brown, or gray, that part of the branch is dead. Move closer to the trunk or back from the tip, and continue to scrape other small areas until you can determine just where the living tissue begins. Use a thinning cut to remove dead or broken branches.

Rubbing or Crossing Branches. When you prune, look for branches that cross or rub. Crossing branches can restrict sunlight and air circulation in the center of the plant; rubbing damages bark, creating entry points for disease organisms. Also look for branches that are parallel but simply too close together, so that one shades the other. In either case, remove the weaker branch.

Water Sprouts and Suckers. Water sprouts are fast-growing branches that arise on the trunk or branches and grow straight up, producing little, if any, fruit. They often appear at the site of old pruning wounds. Remove them as soon as you notice them, regardless of the time of year.

Pruning an Open Center Tree

A mature open center tree has a short trunk with three to four strong, evenly spaced scaffold branches around it. Training starts the first season after planting.

First-Year Training

The first summer, remove any branches that are less than 18 inches from the ground. The branches that grow from the top 2 or 3 buds will have narrow, weak crotch angles; cut them back to 2 or 3 buds. Then select scaffold branches from among the lower branches. Look for branches with wide crotch angles that are spaced 3 to 5 inches apart vertically along the trunk and radiate evenly around it. Don't despair if you don't have any potential scaffold branches, or only have weak-looking ones; they will develop the first summer after the top shoots are pruned away. Use spreading techniques to increase the crotch angles of the scaffold branches you select. The angles should be between 45 and 90 degrees. About a month after pruning, check the tree and cut back any new shoots growing from the top, above the scaffold branches you've selected.

Second-Year Training

The second season, make your final selection of scaffold branches; train a third or fourth scaffold if the tree did not produce enough vigorous growth the previous season. Do this in early spring for most trees; for apricots, peaches, and nectarines, prune after flowering. For the best growth, all scaffold branches should be about equal in size. If one is much larger than the others, cut it back to a lateral branch that is growing toward the outside of the tree. Cut back the shoots that have arisen at the center of the tree—where you removed the central leader last season—to short stubs above the highest scaffold branch. These will sprout again and help keep the scaffold branches growing outward rather than vertically. Use spacing techniques to further widen the crotch angles, if necessary. Thin out lateral branches growing from the scaffolds within 6 inches of the trunk, along with any branches that arise from the trunk itself. This will open up the center of the tree and encourage growth at the tips. Remove any laterals on scaffolds that cross or touch one another, along with diseased or damaged wood. During the growing season, you'll need to head back the center shoots to 3 to 5 inches so that growth continues to be directed to the side scaffolds.

Third-Year Training

By the third year, the basic scaffold arrangement should be well established. Remove completely shoots growing from the center stubs, as the scaffold branches should have attained their permanent shape. Be sure to cut away diseased branches as well as any that cross or crowd the center of the plant.

Maintenance Pruning

The branches of peaches, nectarines, apricots, European prunes, and Japanese plums need annual heading to encourage lateral bud growth and, thus, fruit production. For apricots, use heading cuts to prune away half the length of half the new growth. For peaches and nectarines, cut back all of the previous year's growth to half its length. For plums and prunes, use both thinning and heading cuts to remove approximately one-third of the previous year's growth. Head back the new growth of sour cherries by 1 to 2 inches in June to encourage the growth of lateral leaf buds that will help the tree become more vigorous. Continue to remove crossing or diseased limbs, water sprouts, and suckers.

Suckers are sprouts that arise from the roots of the tree. Remove these as soon as you see them. If you have a grafted tree, the suckers will have the characteristics of the rootstock, not the cultivar you want to grow.

TRAINING AND PRUNING STYLES

Orchardists have developed several ways to train fruit trees, all based on obtaining maximum yield, sun exposure, and ease of care, and determined by the growth habits of the plants.

The ideal sun-gathering shape of a fruit tree is similar to that of a Christmas tree—with evenly spaced scaffold branches arising from around a single trunk. This is the basic shape of a central leader tree, the form most often used for dwarf apples, pears, cherries, plums, and prunes. To a lesser extent, this is also the basic shape of the modified central leader.

Open center trees have three or four main limbs that arise near where the central leader was removed. This form allows good light penetration and is most commonly used for

Continued ➔

peaches, nectarines, apricots, and standard-sized apple trees. Cherries, plums, and prunes may also be pruned as open center trees.

Whatever method you use, keep in mind that each tree presents its own particular pruning problem. Take time to stand back and examine the tree as you prune. Remember, you can always cut a questionable branch off later, but you can't reattach one cut by mistake!

Pruning a Central Leader Tree

It takes several seasons to properly train a central leader tree, but it's well worth the effort. For the first few years of training, the goals are to encourage vigorous growth and a sturdy branching structure.

First-Year Training. If you're starting with an unbranched whip, as soon as growth starts after planting, select the most vigorous shoot arising near the top of the trunk to serve as the central leader. If there is a trunk stub above this branch, remove it. To keep lower branches from competing with the central leader, prune away the next two shoots below the leader if they are less than 8 inches from the top of the tree. If you're starting with a branched tree, the procedure is the same: Select a central leader, remove the second and third shoot from the top if they are less than 8 inches from the top, if they have narrow crotch angles, or if they are growing vertically and crowding the central leader. Then remove any branches that are less than 20 inches from the ground.

The next objective is to choose scaffold branches that will form the framework of the tree. Often there are only two branches for scaffolds in the first summer after planting—more scaffolds will develop in the next few years. Choose vigorous branches with wide crotch angles that are spaced between 5 and 8 inches apart vertically and radiate evenly around the trunk. No two branches should be directly above one another. Use one of the spreading methods described earlier if the crotch angles are less than 45 degrees. If there are more branches than you need for scaffolds, cut them back to 4 inches from the trunk to encourage fruiting and to direct growth into the selected scaffold limbs. Pinch these branches monthly throughout the growing season, from June through August. (After a few seasons, once the primary scaffolds are bearing well, you can either remove the branches that you pinched or cut them back to a fruiting spur in the middle of the summer.)

Second-Year Training. Start second-year training by making a heading cut on the central leader to about 1½ feet above the highest scaffold branch. This will encourage new scaffold branches to form higher on the tree. Make a final selection for the lower main scaffold branches and spread these limbs so the branch angles are between 45 and 90 degrees. Head back these scaffold branches by pruning off the tips if they grew vigorously the year before; if growth was thin and weak, cut them back severely. Strive for a cone-shaped tree, leaving lower scaffold branches longer than those near the top. This will encourage development of secondary scaffolds and strengthen the primary scaffolds.

When growth starts, select the most vigorous shoot that arises from the tip of the central leader, and remove the second and third shoots that arise below it to ensure that it won't have to compete with other branches. Choose additional primary scaffold branches, using spreading techniques as needed. Head back any extra branches not needed for scaffolds to 4 inches as in the first growing season. Remove any suckers or water sprouts during the summer months. Continue pinching the small branches you pinched throughout last season.

Third-Year Training. Follow the directions for second-year training both early in the season and after growth starts. Remove any crossed or touching limbs. Continue spreading the scaffold branches—use the fabric tie-down method to spread these branches to a proper angle. Once growth begins, remove any water sprouts or suckers. If fruit is being borne on the leader, remove it if the leader begins to droop or stake to keep the central leader upright.

Maintenance Pruning. The fourth year, and every year thereafter, you'll need to prune to maintain the shape of the tree. A mature tree should have six to eight main scaffold branches. After the tree has reached its mature height, prune the central leader and the main scaffold branches back to weak lateral branches. Be sure to retain the cone shape of the tree, with lower scaffolds longer than higher ones.

Scaffolds that have fruited for several years will often droop downward because of the weight of the fruit. Don't remove all of these or you will reduce fruit production near the bottom of the tree. Drooping branches that have fruited for three or four years can be cut back to a side branch that points toward the outside of the tree.

Continue with standard annual pruning. Remove water sprouts and suckers, along with broken, diseased, or crossing branches.

Pruning a Modified Central Leader Tree

The modified central leader tree closely resembles one trained in the central leader style, and, in fact, for the first few years the training is exactly the same. After four or five main scaffold branches have been selected and trained, cut the central leader to just above the highest scaffold branch. This will open the center of the plant to sunlight. Cherries, plums, prunes, and some vigorous cultivars of apples and pears are often trained as modified central leaders.

Espalier

Having a small yard should not stop you from harvesting an orchard's worth of fruit. Dwarf fruit trees and decorative espalier training can greatly increase your yard's potential for fruit production. Espaliered trees, trained to grow flat rather

than three-dimensionally, can be grown upon a trellis in shapes as simple as a single, nearly unbranched trunk with fruiting spurs along its length or as complex as a criss-crossing Belgian fence. Whatever the shape, this system of training and pruning has many advantages. Individual trees can be spaced 1½ to 2 feet apart when grown as a single cordon, or branch, making it easy to find room for a wealth of cultivars.

WHY GROW ESPALIERED TREES?

Espaliered trees have much to offer the home gardener. Although they are small, their yield per space is quite high. An apple tree trained to a single branch, called a cordon, that is 6 to 7 feet tall can bear from 4 to 8 pounds of fruit. Peaches, nectarines, apricots, plums, and cherries trained in the shape of a 7-foot-tall fan and spaced 12 to 20 feet apart can each bear 12 to 30 pounds of fruit. Since the plants don't require as much space as conventionally grown trees, you'll have room for more cultivars. By selecting both early- and late-ripening ones, you can spread your harvests over a long season and grow just the right amount of fruit for your use. Espaliered trees begin to bear earlier than standard trees—within the third to fourth year from planting. The fruit colors and ripens well because it receives plenty of sunlight. Pruning, picking, and pest control are easy because everything is within view and reach. In cooler climates, espalier training can permit the growth of marginally hardy cultivars if the trees are planted next to a south-facing wall to take advantage of reflected heat.

While espalier training has many advantages, it takes more time and dedication to erect a sturdy trellis and carefully train and prune to achieve and maintain these tree shapes. As with most garden choices, perhaps the saying "Know thyself" is the best when determining whether this method is for you. For those of you who don't want to train trees into this shape, some nurseries offer pre-trained trees so all you need do is maintain the shape after planting.

GETTING STARTED

While you can put espalier fruit trees anywhere you can place a trellis, there are some places that especially lend themselves to decorative trees. Driveway edges, borders of vegetable or flower gardens, and the outer edges of decks are good locations for espalier fruit trees. For instance, you might want to screen in your deck or patio area with artful panels of apples or pears grown in the latticed pattern of a Belgian fence. Espalier fruit trees also can be trained directly to a wall or fence, without a trellis. However, remember that it will be almost impossible to do any maintenance on the wall once the espalier tree is growing up against it. So, do not place espaliers against wood siding, wooden door frames or windows, or a fence that will require painting. If you still would like to take advantage of reflected heat but need to maintain a wooden wall, place the trellis at least 2 feet from the wall for easy maintenance access. In climates where daytime temperatures often exceed 90°F, trees should be planted away from any walls on a free-standing trellis so that trees and fruit will not be burned by excess heat reflected from walls.

Trellis Guidelines

You can support espaliers on pipe or wooden posts strung with horizontal, vertical, or diagonal strands of heavy 14-gauge wire. If your area has high winds, you might want to use plastic-covered wires so that the branches aren't injured as they rub up against the wire. Space wires 15 to 24 inches apart, with the first wire about 15 inches above ground level. On fences or walls, the highest wire should be at least 6 inches below the top of the structure for best appearance. If you choose to grow against a wall, fasten the branches to a system of wires that is spaced 2 to 4 inches from the wall.

Choosing Trees for Espalier Training

For best results, start with fruits that bear on long-lived short spurs, such as apples and pears. These can be trained relatively easily to many different shapes. Trees that bear mainly on lateral branches (one-year-old wood) or short-lived spurs, such as peaches, nectarines, apricots, plums, and cherries, are more difficult and less adaptable. In order to maintain fruit yield, you need to prune these plants to provide a constant source of new wood.

Choose trees with dwarfing rootstocks so that the shape of the tree will be easier to maintain. (For apples, trees grafted on M9 or M26 rootstocks work well on loam soil while more vigorous MM106 rootstock should be used on heavy or sandy soils. Pears should be grafted on Quince A or Quince C rootstocks.) Choose unbranched young trees for easiest training.

Espalier Shapes for Best Yields

The best shapes will be determined in a large part by the fruiting habit of the plants you are growing. For apples and pears, one of the easiest and highest yielding shapes is a simple cordon, simply an unbranched tree with fruiting spurs along its length that is either grown vertically or leaning at an angle. This style allows you to grow the most cultivars, and thus the widest variety of fruit, because the trees can be planted as little as 2 feet apart. Pears bear best when trained as a vertical cordon; apples, at an angle. Belgian fence is a form that uses branches growing on the diagonal and is suitable for apples and pears. In this form, each tree has a short trunk with two branches spread at 45 degrees in a V shape. Branches of neighboring trees are woven together to form a decorative panel.

Another way to shape apples and pears is to plant a single tree and train multiple vertical arms from the trunk, making the double-U form.

Trees trained with horizontal cordons have branches growing horizontally along a trellis. These are more difficult to maintain because they work against the plant's natural tendency to grow upward. Trees trained in this manner can have two horizontal cordons or several pairs of cordons. This form offers

Continued →

the advantage of more fruit production in a vertical space. Depending on the length of the horizontal cordons, space these trees 8 to 20 feet apart.

Cherries, peaches, nectarines, apricots, and plums grow best when trained in a fan shape, with permanent branches radiating from the top of a short trunk. This shape allows them the extra space they need for their fruiting wood. Space trees 12 to 20 feet apart.

PRUNING AND TRAINING ESPALIERS

Once you've selected a site, decided what trees you want to grow, and how you want to train them, it's time to plant and begin training. Plant trees just as you would any dwarf fruit tree.

Training Basics

All of the espalier styles require slightly different training, but there are some basic techniques that apply. During early training, lash bamboo canes to the trellis wires in the direction you want a branch to grow. Then train the tips of the fruit branches to the canes. This encourages growth that is ruler-straight and precisely spaced, which is especially important for the more complex designs such as the Belgian fence. Use twine, rawhide, plant ties, cloth strips, or any material that will not constrict the branches when tying them to the trellis. As you train to establish the plant's basic framework, do not simply remove all unwanted lateral branches.

Basic directions for training several popular styles of espalier are described below. Whatever shape you are making, do not let the tree fruit until training is finished, so that all the tree's resources are concentrated on fast vegetative growth. If the tree blooms, remove the fruit right after the blossoms fall.

Cordons. To train trees as simple, unbranched cordons that are vertical or diagonal, simply tie a bamboo cane to the horizontal wires of the trellis and then tie the stem of each tree to the cane. After the tree has grown to the top of the trellis, cut it above a bud at the desired height.

U or Double U. Although it takes a couple of growing seasons to train an espalier in a U or double-U shape, these are both attractive styles that are relatively easy to maintain. Once growth starts the first spring, cut the tree back to a bud just above the wire that will support the bottom of the U. Select the two best of the shoots that sprout, and train them to bamboo canes set at a 45-degree angle from the main stem. As the season progresses, lower and tie the two side arms to the first horizontal wire so they form a 90-degree crotch angle. Once they have grown long enough to form the bottom of the U, allow the tips of the stems to turn upward and train them to the top of the wire.

To form a double U, train as above and then clip each side shoot just above a trellis wire. Use bamboo canes to train two more side shoots into U shapes.

Belgian Fence and Fan. The Belgian fence and fan-shaped espalier forms are similar in design. Cut the tree back to the height of the lowest wire. For the Belgian fence design, train the top two shoots to grow in opposite directions, using bamboo cane lashed at 45 degrees to the trellis wires. As the shoots grow and intersect, the branches are woven together to form a lattice design. For the fan design, allow three to seven branches to grow from the top of the trunk and train them into a fan pattern.

Controlling Growth and Increasing Yields

Once you have the basic framework established, you'll want to begin managing the tree's growth to keep it under control and maximize fruit yields. Although conventionally grown fruit trees are pruned heavily in early spring, the best way to prune espalier-trained fruit trees is to pinch or rub off unwanted growth throughout the summer as it appears. For example, buds that will produce an unwanted or misdirected branch should be rubbed off in the early spring. If the bud opens, pinch off the growth, taking care not to damage the bark. In late summer, when shoots are longer than 9 inches and the bark is starting to turn from green to brown at the base, trim the shoot back to three leaves beyond where growth began in the spring. (There will be a rosette of smaller leaves around a circular fold in the stem where growth began in the spring.) This will encourage the development of fruit spurs at the base of the branch in the next growing season.

To encourage fruit spur formation, cut weak, year-old laterals to 4 or 5 buds during midsummer. The top buds will grow into vegetative shoots while the bottom buds are most likely to become fat fruit buds. During the next spring, before growth begins, remove the vegetative shoots, leaving only the fruit buds. When vigorous side shoots branch off the end of the cordon, control growth by bending and tying the branch into a horizontal position. If you can do this early in the season, within the first month or so of growth, fruit buds will form along the branch. Before growth begins in the next spring, cut the branch back to a fruit bud to remove the vegetative growing points and make a fruitful spur. If fruiting spurs occur unevenly along the cordon, you can often turn a dormant bud into a fruit spur by making a shallow notch ⅛-inch wide and 1/16-inch deep just below the bud, as soon as the tree begins to leaf out. If you place the notch above the bud, it will often turn into a vegetative branch. To prevent more vertical growth, use one of these spur-forming techniques to turn the top bud of your espalier into a fruitful spur.

On older apple and pear espalier plantings, the fruit spurs become very branched and thick with fruit buds. Thin out some of the buds so that there is space between them. For the best fruit quality, thin to one fruit per flower cluster.

Grafting Fruit Trees

Grafting is a technique used to join parts of two or more plants and cause them to grow together into a single plant. This may seem like a specialty with little relevance to home gardening, but grafting is much more common than one might think. In

fact, most fruit trees sold today are grafted. In addition, grapes, modern roses, and many specialty trees and shrubs are also grafted.

Most dwarf and semidwarf fruit trees are a product of grafting. They are composed of a fruiting cultivar grafted onto a rootstock that affects growth rate and size at maturity. Grafting can also be used to add a pollinator to a tree that requires pollen from another cultivar in order to set fruit. In a technique called top working, grafting can be used to change the fruit cultivars growing on an established tree or to add fruit cultivars to a tree. (A tree can be topworked with one or several cultivars.) This technique also can be used to save a tree whose branches or top have been damaged by disease or weather.

Grafting Basics

All grafted trees consist of a stock and a scion. The stock is the plant that provides the best root system for the tree. The scion is the cultivar you've chosen for its good fruiting characteristics. In some cases, a third piece is added—the interstem—if the stock and scion aren't compatible and won't graft well with each other. The interstem is compatible with both, and is grafted between them.

The actual process of grafting involves pressing the cambium—the actively growing tissue of the stem located in a thin layer just under the bark—of the stock and the scion against one another so they grow together. There are several types of grafts, but for any of them to be successful, the cambium of stock and scion must be lined up as close together as possible. Cuts on both should be clean and fresh. After positioning stock and scion, they must be held immobile so the cambium will have a chance to join. It's important to seal any cut ends with grafting wax to make sure the tissue doesn't dry out.

Most grafting is done with cultivars of a single fruit type—grafting one or more apples onto one tree, for example. Surprisingly, different fruit tree species also can be grafted on the same plant. In this case, the compatibility of the tissues from the different stocks and scions is important; incompatible plants will fail to graft together, or they will form a weak graft that breaks easily under stress. As a general rule, nearly all grafts within a single species will be successful. Many grafts within a single genus are also successful. Plums, apricots, nectarines, and peaches all belong to the genus *Prunus*. Some potential combinations among these plants include: plums grafted onto an apricot rootstock or tree; apricots grafted onto peach rootstock; nectarines or Japanese plums grafted onto European plum stock; and apricots and nectarines grafted onto Japanese plum stock. Citrus fruits can be grafted in a similar manner, with grapefruits, lemons, and oranges grafted onto an orange rootstock. When grafting apples, use cultivars with similar growth rates, because a slow-growing cultivar won't graft well with a fast-growing one.

Obtaining Scions

Whether you are planning on topworking an existing tree or are planning to graft onto a seedling that appeared in your yard, the first step is to find scion wood of a cultivar you'd like to grow. Scion wood, the fruiting cultivar, is gathered when the tree is dormant—either in the fall or before buds swell in the spring. You can cut scions from a neighbor's tree or ask a nearby orchardist for them. However, be aware that many new fruit cultivars are Plant Variety Protected (PVP), and it is illegal to propagate them or use portions of them to graft other trees. Some mail-order nurseries offer scion wood.

Scions should be cut from narrow (about pencil width), straight wood produced in the last year. Cut the scions into 6- to 12-inch-long pieces, each with 3 or 4 leaf buds. Always cut above a bud. As you gather and cut scions, bear in mind that when you graft you'll need to align the bottom of the scion with the top of the stock; the scions will die if they are inserted upside down into the stock. An easy way to keep track of which end is which is to make a slanting cut on the bottom, a straight cut on top. Tie the scion pieces in a bundle, put them in a plastic bag with moist peat or sawdust, and store them in a refrigerator.

Types of Grafts

The grafting method you use will depend upon the size of the stock. Whip and tongue grafting is generally used to graft small pieces of wood, while cleft grafting is used for 1- to 2-inch diameter stock. Bark grafting is used when the stock is 4 or more inches in diameter. If you can, always make more grafts than necessary, so there is a better chance that some will be successful.

Whip and Tongue. Whip and tongue grafting is one method used to produce commercial fruit trees and to graft pollinator branches or add cultivars to a young tree. It is usually done in early spring while the plant is still dormant and is used to join stock and scion that are nearly the same diameter, generally less than ¾-inch diameter. Whip and tongue grafting is often called tongue grafting or whip grafting.

Cut the stock back to within a few inches of the ground if you are grafting to a planted rootstock cultivar; cut back a young branch close to the trunk if you are topworking a small tree. For the best results, the stock and scion need to be as close in diameter as possible.

Using a sharp grafting knife, make complementary long, diagonal cuts on the top of the stock and the bottom of the scion. The cut surface should be about 1½ inches long on both stock and scion. Make a second cut on each piece parallel to the first, about an inch below it, downward to the center of the stem. This forms the tongue-shaped piece on both parts. When the two pieces are fitted together, they form a tongue and groove joint. Line up the cambiums and wrap securely with a strip of rubber band, latex nursery tape, or plastic electrician's tape. If the two pieces aren't exactly the same diameter, don't just center one

Continued ➔

piece inside the other—line up the cambiums on at least one side of the graft. (Matching diameters with both sides lined up are preferable.) Cover all the cut surfaces with grafting wax or asphalt emulsion sealing compound. Once the scion begins to grow, remove the wrapping.

Cleft. Cleft grafting is a useful technique for topworking established fruit trees. You can cleft graft a new fruit cultivar onto a tree that has a damaged top or is not producing well, or add extra cultivars to the tree.

Cleft grafting should be done late in the dormant season, before the buds open. In this method, two pencil-width scions are inserted in a cleft made in a fairly upright young branch.

The ends of the short scions should be cut just above a bud and have 2 to 3 buds per piece. Shave the base of each scion so that it is wedge-shaped. The edge that is on the inside of the cleft should be narrower than the edge on the outside. There should be bark on both the narrow inside edge and the wider outside edge. The end of the scion should be blunt, not tapered to a sharp point.

The limb to be grafted, called the stock, should be between 1 and 2 inches in diameter. Cut the stock straight across with a fine-toothed saw for a smooth, even surface. Then use a hammer and chisel to split the center down 4 to 6 inches to form a cleft in the trunk or branch. The depth of the cleft will be determined by the diameter of the scion, which must fit tightly in the cleft. Using a screwdriver to keep the cleft open, insert the scion so that the side with the wider piece of bark is toward the outside of the branch. For the graft to form, you'll need to align the cambiums by pushing the scion toward the center of the cleft slightly so that the tissue just under the bark of the stock is pressing against the same tissue of the scion. Remove the screwdriver once the scion has been aligned. Wax the area and the tips of the scions as soon as the fitting is done. Wait until the following spring to cut off the weaker graft if both take.

Bark. For larger branches, bark grafting is the best technique. This can only be done in the spring, when the bark "slips," or peels easily away from the rest of the tree. Prepare three narrow scions (more if the stock or trunk is very large) about 5 inches long. Make a 2-inch downward diagonal cut on one side of the bottom of the scion and then a slightly smaller cut on the other side, making a very thin wedge. To prepare the stock, cut away the branch to be grafted—if you're replacing a broken or diseased branch cut back to healthy wood—by making a straight cut across the wood as you would for a cleft graft. Then, starting at the top of the stock, make a 2-inch slit in the bark. The bark should slip easily away, leaving the cambium exposed. Place the scion under the bark of the stock, with the longer cut side of the scion facing the inside, against the cambium. Use a small finishing nail to fix the bark and scion in place, then wax the area and the tips of the scions to keep them from drying out.

Budding Fruit Trees

Budding is a slightly different form of grafting that can be used to change or add fruit cultivars to a tree. In this case, all you need from the scion branch is a bud. The easiest technique is T-budding. Unlike grafting, T-budding is done in mid- to late summer, after the buds for next year have formed and become dormant but while the tree's bark still slips.

1. Cut a 1-foot scion from a newly grown branch. Remove the leaves, leaving the petioles (stems holding the leaf to the branch). If you can't bud right away, wrap the budstick in plastic and keep it cool. Refrigerate in a glass of water if left overnight.
2. Choose a stock branch or trunk that is pencil-sized, and make a T-shaped cut just through the bark. Using the rounded top of a budding knife (or another blunt, rounded edge such as a fingernail), gently lift the flaps of the cut, which should slip away, exposing the cambium.
3. Select a healthy bud from the middle of your budstick and make a shallow cut ½ to ¾ inch below the bud and end ½ inch above it. Slide the knife out. To release the bud, make a perpendicular cut down into the wood ½ inch above the bud. The bud is now free and looks like a little shield.
4. With the bud pointing upward just as it was on the scion, slide the shield—cut side against the wood—into the flaps of the T-cut until it is covered.
5. Press the bark over the sides of the shield and then carefully wrap the area with a strip of rubber band, leaving the bud uncovered. Rub off any buds on the stock that may compete with the grafted bud.
6. When the bud you've selected begins to grow, remove the rubber band. The following spring, after the graft has grown 2 to 3 inches, cut the stock branch above the bud, making a slanting cut back away from the bud. This will encourage bud growth. In the South, this can be done in the same growing season as budding because bud growth will start so quickly.

Controlling Pests and Diseases

Nothing will dampen your gardening enthusiasm more than the unhappy discovery that your carefully tended trees have been damaged by pests or disease, reducing yield and possibly leaving the fruit inedible. There are steps you can take to avoid this scenario without resorting to the use of poison sprays. In

considering your options for fighting pests and disease, remember to weigh your effort, expense, and any possible environmental damage against the amount of harm your trees will suffer. Some insects and diseases cause mainly cosmetic damage to trees or fruits, while others can completely kill your trees.

Watchfulness Pays. Don't forget about your trees between planting or pruning and harvest time. Check them frequently for signs of insect or disease infestation. Telltale clues include: holes in leaves; wilting; shiny coatings on leaves; holes or cuts in fruit; yellowing or brownish areas on leaves; premature defoliation; rotten spots on leaves or fruit; distorted growth; and blistering or rupturing of bark. Pheromone or sticky traps are useful for giving early warning of the arrivals of some species of harmful insects.

Know Your Enemy. Once you identify a specific problem, learn about the life cycle of the pest involved. Many trap and barrier control measures are linked to stopping a pest at a particular point in its life cycle. For example, cankerworms, which skeletonize leaves, can be combated by tying a band of sticky material around tree trunks in fall and again in February to catch wingless adult females which would climb the trunk to lay eggs in the trees.

Encourage Pest Predators. Birds eat enormous numbers of insects and insect eggs hidden under tree bark. Encourage them to visit your yard by providing birdhouses, feeders, and birdbaths. Parasitic wasps and other beneficial insects also help control many fruit tree pests.

Harvest Thoroughly. At harvest time, remove all fruit on the tree and on the ground. Windfalls or damaged fruit left on the tree are prime targets for infestation by insects or disease. Promptly prune away any branches that show signs of disease. Burn diseased fruit and prunings.

Prune Carefully. Careless pruning can leave stubs or injured wood where diseases can get a foothold. Good pruning keeps the tree open to light and air, discouraging the many disease organisms that thrive in a wet, humid environment. Disinfect pruning tools with bleach between each cut whenever you are working on potentially diseased trees.

Plant Resistant Cultivars. This is one of the most promising ways to minimize disease problems without sprays. For example, 'Madison' and 'Harbelle' peaches and 'Mericrest' nectarine are resistant to cytospora canker, and there are many scab-resistant apple cultivars available. 'Liberty' is the most disease-resistant apple cultivar produced thus far.

Use Horticultural Oil. Oil sprays coat insects on your trees, killing them by suffocation, and break down quickly in the environment. In the past, heavier grade oils, called dormant oils, were the only option available. These should only be sprayed in winter or early spring when trees are leafless. Dormant oil also smothers insect eggs hidden in bark. The new, lighter viscosity oils, called superior oils, can be sprayed during the growing season if environmental conditions are right. These sprays will suffocate spider mites and other soft-bodied sucking insects.

Be a Good Housekeeper. Bacterial or fungal spores and dormant insects can overwinter in leaf litter under fruit trees. Clean up any plant debris around your trees. Cultivating the top inch or two of soil will expose pupae of some insects to weather and predators.

Try Interplanting. As in your vegetable garden, planting different species of trees near one another may have beneficial effects. Cherry trees may form a kind of natural barrier to prevent apple codling moths from finding all your apple trees. And a mixed planting, being more diverse, may attract more birds and beneficial insects.

Spray When Critical. If faced with the choice between spraying or losing your crop or trees, remember that Bt (*Bacillus thuringensis*) and botanical poisons are effective against many tree pests. Botanical poisons like rotenone and pyrethrum can kill honeybees—so be extra careful if spraying at bloom time. Lime sulfur, copper, and Bordeaux mixture are effective against many tree diseases and are considered low in environmental toxicity.

Making Apple Cider

What better way to celebrate your abundant harvest than by making fresh apple cider? It's an easy process that can be done with simple household appliances or hand tools—or if you have one, an old-fashioned apple cider press.

Apples needn't be picture-perfect to yield great tasting cider. You can use your windfalls if you pick them up promptly and store them in a cool area. Surface-blemished apples such as those with scab or hail marks are fine to use, too. Don't use any apples or parts of apples that have spoiled or have brown decay. Use only ripe apples, as green or underipe fruit produces flat-tasting cider. As with many juices, the best ciders are made from a mix of sweet, tart, and aromatic apples. If you grow only one cultivar of apple, you might want to trade some apples with another gardener whose varieties complement your own. Tart apple varieties include 'Winesap,' 'MacIntosh,' 'Jonathan,' 'Northern Spy,' and 'Wealthy,' while sweet apples include 'Red Delicious,' 'Golden Delicious,' 'Gala,' 'Cortland,' 'Rome,' and 'King.'

JUICING APPLES

Though yields will vary between different cultivars, a bushel of apples generally will make about 3 gallons of cider. Keep in mind that fresh cider only lasts in the refrigerator for a few days. However, making hard cider and freezing fresh cider are good ways to preserve this delightful beverage.

The first step in cider-making is crushing the apples. Core the apples and crush or chop them into small pieces in a food chopper blender or food processor. Put the crushed apples into a clean muslin sack—an old, clean pillowcase will

Foiling Common Fruit Tree Pests

Apple Maggots
These pesky insects are the larvae of flies that lay eggs on fruits throughout the growing season. The larvae burrow throughout the flesh, ruining the fruit. Fortunately, it's easy to catch and kill the flies by hanging red spheres coated with an adhesive substance like Tanglefoot from the branches. The flies land on the decoys, get stuck, and die. Hang the spheres with 9 to 18 inches of open space around them. Use one trap for every 100 or so apples you expect the tree to bear.

Cankerworms
Also known as inchworms, cankerworms skeletonize the leaves of apple, apricot, and other fruit trees, weakening the tree so that little fruit matures and the tree sometimes dies. Wrap heavy paper or cotton batting around tree trunks and coat it with a sticky adhesive to stop females from climbing into the tree to lay eggs. Bt (*Bacillus thuringiensis*) sprays are effective against the larvae. Tilling the soil around your trees in the fall may unearth pupae, exposing them to predators.

Codling Moths
Apple codling moth larvae, which burrow into apple, apricot, peach, and pear fruit, can be controlled by spraying Bt (*Bacillus thuringiensis*) just as eggs are hatching. Spherical red sticky traps and oil sprays also help in controlling this pest. Woodpeckers will eat eggs hidden in tree bark. Attract the birds to your trees in the winter by hanging a block of suet on the trunk.

Gypsy Moths
Young gypsy moth larvae, which feed on the foliage of many fruit trees, can be controlled with Bt (*Bacillus thuringiensis*) sprays. Also trap larvae with sticky bands on tree trunks, or foot-wide burlap strips tied around the trunks, with several inches draped over the string. Older larvae feed at night and hide during the day. They will nestle under the burlap, and in the late afternoon, they can be collected and destroyed (wear gloves, as touching the larvae can cause an allergic reaction).

Leafrollers
Fruit tree leafrollers are larvae that spin webs between leaves and fruits, forming a sheltered spot where they can feed on the fruits. They will attack most fruit trees including citrus. Pheromone traps will help monitor if leafrollers are entering your area. Bt (*Bacillus thuringiensis*) or rotenone sprays provide control.

Peachtree Borers
The larvae of these pests tunnel into the trunks of apricot, cherry, peach, and plum trees, weakening and possibly killing the trees. Kill the larvae in the holes they have made by inserting a wire and jabbing it around to spear the pests. Alternatively, spraying Bt (*Bacillus thuringiensis*) into the holes will work, as long as the spray directly contacts the larvae. Borers also can be blocked from entering the tree by encircling the trunk with a piece of tin. Force it down below the surface of the ground, leaving about 2 inches between the tin and trunk. Fill the space with tobacco in late spring to make a barrier against the adult moths, which try to lay eggs near the tree base in late summer and early fall.

Pear Psylla
If your pear trees appear to be covered with soot, they have probably been attacked by pear psylla. These tiny insects secrete a sweet, sticky substance. The soot is actually a fungus that grows in the secretions. Stop pear psylla before it creates a problem by spraying with dormant oil in spring. During the growing season, psylla can be controlled by dusting dwarf trees with diatomaceous earth or ground limestone or by spraying with insecticidal soap.

Plum Curculios
These pests lay their eggs in fruits of most common backyard fruit trees, cutting out crescent-shaped holes and damaging the skin. They can be trapped by taking advantage of their natural tendency to play dead when threatened. As soon as you notice damaged fruit on a tree, spread a white dropcloth under the tree and shake the tree or limbs. The insects will drop from the branches, immobile, and you can collect and destroy them.

do—and squeeze out as much juice as possible. Pour the juice into clean glass jugs or bottles and refrigerate, or just drink right away.

If you have a cider press, its hand- or electric-powered cutting cylinder makes it easy to mince up the apples. Keep your hands and fingers away from the rotating blades. Use a large tub to hold the pulp, a smaller one to catch juice runoff, and a clean muslin sack or cheesecloth for pressing the juice out of the pulp. Once the apples are crushed, fill the muslin sack with enough pulp to fill the press. Crank the press handle until juice no longer runs. Repeat the process with the rest of the pulp. For a clearer cider, try pouring it through a paper filter such as a coffee filter. Many cider presses are designed so that apple pieces are fed into the crusher or mincer, pass through it, and fall into the cloth-lined frame, ready for pressing.

SETTLING AND RACKING-OFF CIDER

If you prefer a cider with a slight bite to the flavor, let it stand at room temperature for three or four days before drinking. Fill clean glass jars or clear or light-colored plastic containers to just below the brim and stopper with a cotton plug (not a regular lid or cap). The plug will pop out if fermentation causes a buildup in pressure. After the cider has settled, sediment will begin to cover the bottom of the container. To "rack-off" the cider, put one end of a rubber tube (about 3 feet in length) in the cider and suck on the other end as you would with a soda straw. As soon as you feel liquid in your mouth, pinch off this end with your fingers and put the tube into an empty container that is lower than the filled one. You've created a siphon that will draw off the clear cider. Stop the process before the sediment at the bottom of the container is disturbed.

FERMENTING CIDER

If you prefer a "dry" cider with more zip, allow the cider to stand longer at room temperature. To prevent the cider from turning to vinegar, it must not be stored in the open air. Close containers with an airlock or a curlicue glass "cork" sold by home-brew suppliers. Or tightly stretch three thicknesses of clean muslin over the bottle opening and secure it well with a rubber band around the neck of the bottle. For fermented cider, use heavy glass or plastic containers, such as those used for making homemade wine, that will withstand the fermentation pressure. After about ten days, the cider will begin frothing and may foam over the top. Clean off the sides of the container, replace the muslin if necessary, and let the frothing continue until fermentation subsides. Once this happens, the sugar in the cider has been turned to alcohol, making the flavor dry rather than sweet. This is often called hard cider. The longer the cider stands, the higher the alcohol content will be.

Storing Fermented Cider

You can store fermented cider in the refrigerator for four or five days. If you want to keep it longer, you'll need to pasteurize it to stop fermentation. Pasteurizing is simply heating the cider to 185°F. To be accurate, use a candy or jelly thermometer to monitor the temperature. Skim off the froth that will probably develop on the top of the cider and pour the hot cider into clean, heated plastic containers or glass jars (heat the containers so they won't crack when exposed to the hot cider). Refrigerate right away, as leaving it on the counter to cool down allows flavor to be lost.

An easy way to store fermented cider is to freeze it. If you plan to freeze it for more than six months, pasteurize it first.

Thinning Fruit

Once your trees begin to bear, you'll probably want to watch each and every fruit mature and ripen. But thinning by pulling off some of the immature fruit is one of the best things you can do to increase harvests and promote better tree health.

WHY THIN?

Thinning is often the most neglected task of fruit tree growing. But fruit on an unthinned tree will be smaller and less sweet. In apples, the decrease in sweetness also means a decrease in storage life. Fruit will take longer to ripen, and in the case of cultivars that are marginally hardy, the crop may not mature before the end of the growing season.

Trees that overbear also will form fewer flowers for the following season and may revert to biennial bearing—only yielding a crop every other year. Fruit trees such as peaches that have overexpended energy in ripening fruit are more likely to suffer winter damage. Furthermore, branches heavily loaded with fruit often break, ruining the tree's form and possibly its bearing potential for years.

THINNING GUIDELINES

Now that you know the importance of thinning, here are a few helpful tips.

- When thinning, use a twisting motion; don't pull. This prevents spurs from being broken or damaged.
- Thin apples, pears, and plums within two months after full bloom (the time when more than half the blossoms were open).
- Thin apricots within the first 38 to 41 days after full bloom.
- Thin peaches and nectarines before the fruit is 1¼ inches in diameter.
- Thin pears, apples, and peaches to only one fruit per cluster or spur. This keeps fruits from rubbing against one another while they are ripening.

Harvesting Tree Fruits

There's nothing better than tree-ripened fruit for fresh eating, jams, jellies, pies, or tarts. Here are some guidelines to help you decide just how and when to pick for best flavor.

WHEN TO HARVEST

Ripe sweet cherries or apricots are delectable right off the tree. It's easy to tell when these fruits are ripe—just pluck and taste one when they've reached full size and have the right color. If they are sweet, they are ripe and ready for harvest. The same applies to apples, peaches, nectarines, plums, and prunes. When ripe, most of these fruits are easy to pick. Use a slight twisting motion as you lift upwards to pick the fruit without damaging the tree.

These rules don't apply to sour cherries and pears. Sour cherries are ripe when you can pull the fruit away from the pit, leaving the pit and stem on the tree. Pears need to be picked when they are full size, but not yet ripe. If pears ripen on the tree, their flesh becomes coarse or mealy in texture. The skin of ready-to-pick pears lightens from dark green to light green and the fruit easily separates from the tree when picked with a slight upward tilting motion. To ripen pears, put them in a cool place (60° to 70°F) and cover with newspaper. Some cultivars such as 'Anjou' and 'Comice' need to be stored for a couple of months at cold temperatures (30° to 32°F) before ripening can occur. A trick that will ripen these cultivars soon after picking is putting the pears and a ripe banana or apple in a closed paper bag. The ripe fruit will release ethylene gas, which induces ripening.

HARVESTING TIPS

- Don't just drop your freshly picked fruit into a bucket—place them in gently. This will extend the storage life of fruit, particularly long-keeping apple cultivars.
- To extend the storage life of sweet cherries, leave the stems attached to the fruit you pick.
- On large trees, fruit on the outer limbs or at the top of the tree often ripen before fruit on the interior; plan more than one harvest.
- Place buckets or boxes of harvested fruit out of the sun as soon as they are filled. This is particularly important for black cherries because the dark color absorbs heat fast, making the fruit spoil quickly.
- Some fruit—plums, prunes, and apricots, for instance—continues to ripen off the tree. You can take advantage of this if your vacation is scheduled for the week these fruits will be ripening. Pick before you leave, and look forward to coming home to ripe fruit! But, peaches and nectarines soften after picking, but don't gain in sweetness—so don't pick them until the fruit is tasty.

Favorite Nuts and Fruits

Growing Nut Trees

Reliably long-lived, often gargantuan in size, and possessing many unique physical attributes, nut trees have become an important part of American culture. Grown since colonial times, nut trees are truly a multipurpose crop, providing shade, beauty, edible nuts, building materials, and wildlife habitats.

SELECTING NUT TREES

People often ask whether they should plant cultivars or seedling nut trees. Named cultivars are produced vegetatively, usually by grafting or budding, yielding genetically identical clones. The advantage of grafted trees is that you know exactly what you are going to get with respect to hardiness, cracking quality, flavor, size, and other crop characteristics. Seeds, on the other hand, are always somewhat different genetically. This genetic diversity can make a stand of seedlings less susceptible to serious insect or disease problems than a stand of genetically identical cultivars.

Where high-quality nut production is of greatest importance, as with pecan or English walnut, stick to named cultivars where available. For trees such as black walnut and butternut, where timber value may be as important as the nut quality, plant a few grafted trees and use high-quality seedlings to fill out the rest of the planting. The resulting forest will be much healthier, and the cost of seedling trees is also a fraction of that of grafted ones.

PLANTING AND CARE

These low-maintenance plants can adapt to a range of sites. They generally need very little extra care once they have been established. Keep in mind that many nut trees, including pecans and most black and English walnuts, need cross-pollination; be sure to plant more than one cultivar or seedling of each kind.

Most nut trees have a deep anchoring taproot, making them a bit more difficult to establish than other trees. Whenever possible, start with small, young trees; they will often adjust more quickly and begin growing sooner than larger trees. Make sure you dig the planting hole deep enough to accommodate the entire taproot.

Unlike fruit trees, most nut trees don't require special pruning techniques to produce good crops. Prune nut trees as you would any shade tree, removing dead, diseased, or crossing branches regularly. If you've planted grafted trees, be sure to prune off any suckers that may arise from the rootstock. For trees that are eventually intended for timber, keep side limbs pruned off to about 12 to 16 feet up the trunk.

Most nuts are best when they are gathered as soon as they become ripe. Remove the outer husk as soon as possible to prevent mold or darkening of the nut kernel. Store the husked nuts in their shells in a cool, dry, rodent-free area. Allow the nuts to cure (dry) for one to three months. After curing, most nuts will keep in the shell for at least a year.

Growing Small Fruit

While tree fruits—apples, peaches, pears, plums, and so on—have similar cultural requirements, the small-fruit crops—blueberries, brambles, grapes, and strawberries—all require widely different care. Fortunately, they're all relatively easy to grow. In the pages that follow, you'll find details on how to plant, prune, train, and care for the most popular small-fruit crops.

BLUEBERRIES

Vaccinium spp.

Ericaceae

Blueberries are among North America's few cultivated native fruits. They have become one of the most popular fruits for home gardeners for their ornamental value, pest resistance, and delicious berries. Only their soil requirements keep them from being more widely planted.

Northerners grow two species of blueberries: *Vaccinium corymbosum*, highbush, and *V. angustifolium*, lowbush. Southern gardeners tend to raise *V. ashei*, rabbiteye blueberry. All three bear delicious fruit on plants with beautiful white, urn-shaped flowers and bright fall color. Here's a rundown:

Lowbush blueberries: Although the fruit of the lowbush blueberry is small, many people consider its flavor superior to that of other blueberries. These extremely hardy plants are good choices for the North. They bear nearly a pint of fruit for each foot of row. Lowbush plants spread by layering and will quickly grow into a matted low hedge. Zones 2 to 6.

Highbush blueberries: Highbush are the most popular home-garden blueberries. Growing 6 to 12 feet or more in height, each bush may yield 5 to 20 pounds of large berried in mid- to late summer. Crosses between highbush and lowbush species have resulted in several hardy, large-fruiting plants. They grow between 1½ and 3 feet tall. Highbush blueberries vary in hardiness, but many cultivars grow well in the North if you plant them in a sheltered spot. Zones 3 to 8.

Rabbiteye blueberries: Rabbiteyes are ideal for warmer climates. They'll tolerate drier soils than highbush plants can, although they may need irrigation during dry spells. The plants grow rapidly and often reach full production in four to five years. They grow from 10 feet to more than 25 feet high and may yield up to 20 pounds of fruit per bush. Rabbiteyes do not grow well in areas that are completely frost-free, however, because they need a chilling period of a few weeks to break dormancy and set fruit. Zones 7 to 9.

Planting and Care

Blueberries require full sun and well-drained, moisture-retentive, acidic soil with a pH of 4.0 to 5.0. Of the three species, highbush blueberries are the most finicky about soil. Blueberries generally grow well in soil enriched with acidic organic material, such as peat moss, composted pine needles or oak leaves, or compost made from pine, oak, or hemlock bark. Fertilize with acidic fertilizers, such as cottonseed meal or soybean meal. Blueberries enjoy a thick, organic mulch.

Most blueberries are not entirely self-pollinating. Plant at least two different cultivars near each other for adequate cross-pollination. Blueberries grow slowly and don't reach full production until they're six to eight years old, so get a head start with two- or three-year-old plants.

Like most bush fruits, blueberries benefit from pruning as they become older. Yearly pruning helps to encourage large fruits, maintains productivity, and lets sunshine into the bushes, which aids in ripening the berries. Late winter is the ideal time for pruning.

In general, both highbush and rabbiteye plants respond to the same type of pruning. For the first three to four years, prune only to make sure each bush is growing in a strong, upright shape. If the fruit buds are too numerous, remove some of them to get fewer but larger berries. (You can distinguish fruit buds on the dormant plants because they are fatter than leaf buds.)

Harvesting

Blueberries ripen over a long season, and you don't need to pick them daily like strawberries. Different cultivars ripen to various shades of blue, so be careful not to pick them too early if you want the best flavor; taste them to determine when they're at their peak. Don't pull berries from the stem; instead, gently twist them off with your fingertips. If the berries don't come off with slight pressure, they're not ready for harvest. Blueberries keep for several days after picking if you keep them cool and dry. They are also ideal for freezing.

Preventing Problems

Although commercial growers encounter a variety of insects, home gardeners rarely have any problems. The blueberry maggot and cherry fruitworm are the most troublesome insects that are likely to appear. Reduce the chances of damage by cleaning up all the old fruit in a planting before winter.

Diseases are seldom a concern in the North but tend to be more common in the South. Botrytis tip blight kills new growth, and stem canker causes cracks in the canes. Cut away any growth that shows signs of abnormal appearance. Mummy berry makes the fruit rot and fall off. To prevent it, plant resistant cultivars, keep the berries picked, and clean up any dropped fruit. Viral diseases, such as stunt, are difficult to control and invariably result in the gradual deterioration of the plant. Buy from a reputable nursery to get disease-free plants.

Nut Trees for Home Use

Besides producing a tasty crop, many nut trees are beautiful, long-lasting landscape specimens. You may want to try planting some of the nut trees described below in your home landscape.

Plant Name	Cultural Requirements	Size and Zone	Comments
Almond (*Prunus amygdalus*)	Rich, well-drained soil. Blossoms cannot withstand late spring frosts.	Small (20'–30'); Zones 7–9	Beautiful flowers, blooms very early, drought-tolerant; limited range.
Butternut (*Juglans cinera*)	Prefers rich, deep soil, but will tolerate a range of conditions.	Medium (40'–70'); Zones 3–7	Graceful; may be toxic to some plants; susceptible to disease; nuts stain pavement.
Chestnut, Chinese (*Castanea millisima*)	Light, upland, sandy loam soil.	Small (10'–20'); Zones 5–8	Ideal for small sites; prickly burrs surround nuts. Many Chinese-American crosses available.
Chestnut, European (*Castanea sativa*)	Rich, upland, loamy soil.	Large (50'–90'); Zones 5–8	Long-lived, stately; prickly burrs surround nuts; needs a pollinator. Mostly grown from seed.
Filbert, hazelnut (*Corylus* spp.)	Rich, light, well-drained soil.	Small (10'–40'); Zones 2–8	Crimson fall foliage; husks litter ground. Grow as a hedge, multi-stemmed bush, or small tree.
Heartnut (*Juglans ailantifolia* var. *cordiformis*)	Deep, rich soil.	Medium (30'–60'); Zones 5–8	Light-colored bark, lacy foliage, fast-growing; may be toxic to some plants; nuts stain pavement.
Hickory, shagbark and shellbark (*Carya ovata* and *C. laciniosa*)	Rich, upland soil; tolerates a wide range of sites.	Large (60'–120'); Zones 3–8	Stately, long-lived; husks litter ground.
Pecan (Carya illinoinensis)	Deep, rich, moist bottomland is required.	Large (70'–150'); Zones 6–9	Stately, long-lived; husks litter ground. Grow strongly once established.
Walnut, Eastern black (*Juglans nigra*)	Rich, deep soil; tolerates a range of sites.	Large (60'–120'); Zones 4–8	Lacy foliage, stately; may be toxic to some plants; nuts stain pavement.
Walnut, Persian (*Juglans regia*)	Rich, deep soil.	Large (50'–90'); Zones 5–9	Stately, fast-growing; may be toxic to some plants; nuts stain pavement.

Birds are unusually fond of blueberries. To prevent damage, cover the bushes with tightly woven netting before the berries begin to ripen.

BRAMBLES

Rubus spp.

Rosaceae

Raspberries and blackberries are among the most delicious and desirable berries you can grow. They are frequently treated as gourmet fruit, but because they don't ship well, not because they are hard to grow.

Brambles can produce fruit for 10 to 25 years. It's important to choose cultivars that have the characteristics you want and that suit your climate. Here's a rundown:

Raspberries: There are two types of raspberries: summer-bearing and fall-bearing. In some areas of the country, their bearing seasons may overlap, so you can harvest raspberries from early summer until frost. Red and yellow cultivars are summer- or fall-bearers. Black and purple raspberries are all summer-bearers.

Red and yellow raspberries are the easiest raspberries to grow. Their fruit is both sweet and fragrant.

Black raspberries are not as winter-hardy as red ones, but tend to tolerate more summer heat. They also are more prone to viral and fungal diseases and have stiffer thorns. The berries are seedy but have a very intense flavor. They are good eaten fresh or in preserves.

Purple raspberries are hybrids resulting from crosses between reds and blacks. The canes are generally more winter-hardy than the black parents. They tend to be very spiny and productive with large, intensely flavored berries.

Blackberries: In general, blackberries are less winter-hardy than most raspberries. In northern areas, the roots may survive without protection, but the overwintering canes are often killed above the snow line. But because blackberries tend to be extremely vigorous, even a very short portion of surviving cane will often produce a surprising amount of fruit.

Blackberries can be divided into three general groups: erect, semi-erect, and trailing.

The erect type has strong, upright canes that are usually thorny and don't require support. They tend to be more winter-hardy than the other types and produce large, sweet berries.

Semi-erect blackberries are thornless and more vigorous and productive than the erect type. Most of them grow better if supported. The fruit is tart and large. The plants bloom and mature later than the erect type.

Trailing blackberries, or dewberries, are the least winter-hardy. They need support, are early ripening, and have large wine-colored to black fruit of distinctively good flavor.

Hybrids: Raspberry-blackberry hybrids combine the characteristics of their parents. Most of them are very winter-tender. Some are thornless. The fruit resembles blackberries.

Planting and Care

Plant brambles in a sunny site with good air circulation and well-drained soil. Start with disease-free stock, and plant in very early spring. Plant in hills or rows well away from wild or abandoned raspberries, which may carry diseases. Provide posts or a wire fence to support the canes.

Row spacing should be wide enough to allow sunlight and air to reach all plants and to allow you to walk or mow between the rows without damaging yourself or the plants. For home gardeners this means at least 5 feet between rows for raspberries and 7 feet for blackberries.

Some types of brambles produce suckers. Red and yellow raspberries spread 12 to 15 inches a year, so plant 1 to 2 feet apart, depending on how soon you want a solid hedgerow. Blacks and most purples don't sucker but form clusters of canes from their crowns. Plant them 2½ to 3 feet apart. Blackberries sucker vigorously; space them 5 to 6 feet apart in rows.

Brambles are self-pollinating. Well-maintained plantings may fruit heavily for many years, but disease often appears as plants age. Plan on establishing a new raspberry bed every ten years (less if plants begin to decline).

Pruning and Training

For black, purple, and summer-bearing red raspberries, cut off all fruit-bearing canes at ground-level as soon as harvest is over, or when growth begins in the spring. In late winter or early spring, thin out new canes that emerged the previous season; save the sturdiest ones and leave six canes per hill or 6-inch spacing between row-planted canes. Shorten lanky canes to 4 to 5 feet. Since black and purple raspberries fruit most heavily on side branches, induce side branching during the summer by pinching the growing tips of canes when they reach 2½ feet. The following late winter or early spring, shorten the side branches to about 1 foot.

For fall-bearing red raspberries, remove fruiting canes each summer as soon as the second fruiting is complete. Or sacrifice the second berry crop (which may be light anyway) and cut the entire planting to the ground as soon as leaves drop in the fall. Although this approach yields only one crop instead of two, it has several advantages. Pruning all canes to the ground eliminates winter injury to canes, results in vigorous new canes for next fall's crop, and cuts down on overwintering pests that will appear next spring.

On erect blackberries pinch the tips of 3-foot canes to force growth of lateral shoots. During the dormant season, shorten all lateral shoots to about 1½ feet. For both types of blackberry, cut away all fruiting canes right after harvest. In winter thin out canes, leaving three or four canes per clump for erect types and eight to twelve canes per clump for trailing types.

Trellising

Though many brambles can be grown without a support system, all are best grown on a trellis. Trellising reduces disease problems, saves space, and speeds pruning and picking.

V Trellis. Summer-bearing raspberries do well on a V trellis. Construct it as follows:

1. Set a sturdy 4-inch post at each end of the row and about every 20 feet in between. Posts should be set at least 2 feet deep and extend 4 to 6 feet above ground.
2. Add a 2-inch x 4-inch cross arm, with notches cut on each arm, to hold wires. The height of the cross arms will depend on how vigorous your brambles are. Try putting them about 3 feet high, and move them if necessary.
3. Cut two lengths of 12- or 14-gauge wire or synthetic baling twine a little longer than the trellis, and fasten the ends to either side of the endpost cross arms.
4. After pruning, put the wires in the outer notches, and arrange the canes outside the wire. Tie each cane

Continued ➔

individually to the wire. Or use two sets of wires on each side of the cross arm, and sandwich the canes between them. After harvest, move the wires to the inside notch to keep the new canes upright.

Hedgerow Trellis. All types of bramble fruit do well when supported by a hedgerow-type trellising system. To construct it:

1. Set a sturdy 4-inch post at each end of the row and about every 20 feet in between.
2. Hammer upward-slanting nails into both sides of each post 3 feet and 4 feet above the ground.
3. Cut four lengths of wire slightly longer than the trellis and twist the ends of the wires into a loop to fit over the end nail.
4. After pruning, lift the wires onto the nails to hold the canes upright between them. (Future pruning is easier if you can remove the wires, so don't staple them to the posts, just rest them on the nails.) Tuck new canes between the wires. A variation of this trellis uses 1-foot cross arms to hold the wires farther apart.

Harvesting

Brambles ripen in early summer. Red raspberries tend to ripen first, followed by black raspberries, and even later by blackberries. Berries do not keep ripening after harvesting. For best flavor and ease of picking, wait until they are fully ripe. Some raspberries offer a slight resistance to picking even when fully ripe. Let your taste tell you when to pick. Red raspberries vary in color at maturity from light to dark red. Some purple ones change from red to purple to almost black, with sugar levels increasing as the color darkens. Blackberries, though they also vary in color, are typically shiny black when not quite ripe and dull black when fully ripe. They come off the vines more easily when fully ripe.

Pick your berries as early in the morning as possible while they are cool. If the berries are wet, let them dry before picking. Handle them gently and place, don't drop, them into a shallow container. Refrigerate immediately.

Preventing Problems

Certain common garden pests attack brambles. Aphids can spread viruses. Japanese beetles feed on ripe fruit. Tarnished plant bugs feed on buds, blossoms, and berries. Keep surrounding areas weed-free to limit tarnished plant bugs.

Several viral diseases, which can drastically reduce yields, affect bramble crops. Raspberry mosaic stunts plants and causes yellow-blotched, puckered leaves. Blackberry sterility results in vigorous growing plants that produce only nubbins—tiny, crumbly, malformed berries—or none at all. Leaf curl causes dark green, tightly curled and malformed leaves. Since there is no cure for viral diseases, dig infected plants and dispose of them immediately.

To prevent problems with viral diseases, plant virus-resistant cultivars and purchase plants only from nurseries that sell virus-free tissue culture or certified bareroot plants. Remove all wild brambles within 500 to 1,000 feet, especially upwind, and keep aphids off your brambles because they spread viruses. Plant black raspberries away from red and yellow ones because blacks are more susceptible to viruses.

Several other diseases attack brambles, including anthracnose, powdery mildew, rust, wilts, and root rots.

Since fungi need warm temperatures and humid conditions to thrive, anything you do to keep the aboveground parts of the plants dry will be to your advantage. Select a planting site with good air circulation and drainage. Avoid overhead watering. Keep your rows narrow, and thin canes to recommended densities. Avoid excessive nitrogen. Trellis the canes for best air circulation. Keep the rows weed-free. Remove spent canes immediately after harvest. Collect and destroy all prunings. If fungal diseases have been a problem in previous years, apply lime-sulfur spray in the spring when the first leaves are ¼ to ½ inch long.

Grapes

Vitis spp.

Vitaceae

Grapes make a wonderful treat straight from the vine, or preserved as jelly, juice, or wine. They thrive in full sun, with good drainage and protection from late frosts.

There are four main types of grapes grown in North America: European, or wine grapes (*Vitis vinifera*); American, such as 'Concord' (*V. labruscana*); hybrids between European and American; and muscadine (*V. rotundifolia*).

Vinifera (European) grapes produce most of the world's table grapes, wine, and raisins. They are not as hardy as their American cousins, are much more susceptible to disease, and require more work to harvest a satisfactory crop.

American grapes have a strong grape or "foxy" flavor and slipskins, which means that the berries can easily be squeezed out of the skins. Many good fresh-eating and juice grapes have been selected from the native species.

Plant breeders have crossed and recrossed vinifera and American species and created grapes to satisfy almost every taste and use. Many of them are as hardy as their American parent, to about -10°F, and have good disease resistance.

If you grow seedless cultivars, you probably won't get grapes as large as those on bunches for sale at the market. Commercial growers dip or spray clusters with synthetic growth regulators so they'll produce big berries.

If you live in the far South, you may only be able to grow muscadine grapes. They make good jelly and juice and a sweet wine.

American and hybrid grape cultivars can be grown on their own roots. Vinifera grape roots are very susceptible to phylloxera, a sucking insect native to the eastern and southern United States and now spread throughout the world. Choose vines grafted on American rootstocks. Certain American rootstock cultivars are also resistant to nematodes and the viral diseases they transmit.

Planting and Care

Plant grapes in a sunny site with deep, well-drained, moderately fertile soil and good air circulation to promote disease resistance.

Plant dormant, one-year-old vines in the spring before their buds begin to swell and open. Soak roots in a pail of water with a handful of bone meal for one to two hours before planting. Plant muscadines 15 to 20 feet apart in rows 10 feet apart; plant other types of grapes 8 feet apart in rows 8 feet apart.

Prune each vine back to leave two live buds before planting; also cut back long roots so they'll fit easily into the hole without bending. Leave 1 to 2 inches of trunk above ground and make a shallow basin around the vine to hold water. If you are planting grafted vines, be sure to keep the graft union above ground level.

Pruning and Training

There are many ways to train grapes. One of the most common methods for home gardeners is cane pruning. If you are new to grapes, don't let talk about training and pruning scare you. Grapevines are very forgiving. You can train cane- and spur-pruned vines on an existing fence or wall.

No matter what training method you plan to use, all vines are treated the same until the second winter after planting.

First Growing Season. During their first summer, the vines need to grow a strong root system. Use drip irrigation or a soaker hose, if needed, to keep the soil damp but not soggy. From mid-August on, water only if the leaves wilt so the vines will harden off for winter. Mulch or cultivate to control weeds.

You can let the vines sprawl on the ground the first year, or tie them loosely to a small stake to keep them out of harm's way.

First Winter. Any time from midwinter on, select the strongest, straightest shoot and prune off all the others. Cut the chosen shoot back to two live buds. The result will look very much like the little vine you planted the previous spring. But remember, the first season is for growing roots. Go ahead and cut off all that top growth; you'll have a better plant in the long run. If cold injury is a problem in your area, wait until the buds start to swell so you can see which ones are alive. You may want to select two shoots rather than one as insurance against injury.

Second Growing Season. If you haven't done so already, place a stake in the ground as close as possible to the vine. When new shoots are 6 to 12 inches long, select the sturdiest, most upright shoot and tie it loosely to the stake. Break off the remaining shoots with your fingers. As the shoot grows, tie it to the stake at 12-inch intervals to form a straight trunk.

When the shoot reaches the desired height, break off the small shoots that are growing above each leaf near the base of your trunk-to-be, but don't remove the leaves. Let the sideshoots grow on the five leaf nodes just below the vine head; cut the tip off the main shoot when it grows a few inches or so above the vine head. Prune off any suckers below the soil line as close to the trunk as possible.

If your vine doesn't reach the desired height by the end of the second season, it probably hasn't developed enough roots to produce the size plant you want. Cut the vine back to two buds, and let it try again the next summer.

Fourth Growing Season. In the fourth growing season, vines are ready to bear a normal crop. For large table grapes, give vines 1 inch of water per week. In the fourth and subsequent winters, you may want to keep a few more buds on each cane for the next season. The vigor of a vine will tell you how many bugs it can support. If your wine has many spindly shoots and little fruit, try leaving fewer total buds the next winter. If it has long, thick shoots and few clusters, leave more buds the next winter.

Subsequent Growing Seasons. During the spring through mid-July, position shoots so light penetrates through the foliage. On short-trunk, trellised vines, tuck the shoots behind the catch wires above the training wire. If shoots reach the top of the trellis and hang down, they will shade the fruit and the canes where next year's flower buds are forming. Prune off the tips if they get too long. Pick off leaves and small shoots near fruit clusters to let in light. This is important because it promotes ripening and discourages pests. You may want to remove or thin

Continued →

clusters to increase berry size or improve quality. If you have too heavy a crop, the fruit may be slow to ripen as well.

Winter Protection

There are grape cultivars that will tolerate severe winter cold. You can grow cultivars beyond their normal northern limit by training trunks only 1 foot high and covering vines with mulch during the winter, or by bending whole vines over and burying or mulching them for the winter.

Once grape buds begin to swell in the spring, they become more frost-tender. All species are susceptible to frost damage at temperatures below 31°F. See "Growing Fruit Trees" on page 426 for more information on site selection and frost protection. Autumn frosts seldom cause damage because the high sugar content of the berries keeps them from freezing and the outer canopy protects both the foliage and fruit beneath it. If you live in an area with short seasons, plant an early-ripening cultivar.

Fertilizing

On most sites, careful soil preparation before planting eliminates the need for heavy fertilization. Mulch lightly with compost in late winter each year. Overfertilizing can cause vines to grow rampantly and produce little fruit. When in doubt, don't fertilize. Compost tea and dilute seaweed extract sprays are good general foliar fertilizers.

Harvesting

Grapevines bear by their third or fourth growing season. Harvest when the fruit tastes ripe. Support the cluster with one hand and cut its stem with pruning shears. Handle clusters gently and lay them in a basket or flat. Harvest large quantities in the morning, small amounts any time of day. Move picked fruit to a cool, protected place as soon as possible.

Preventing Problems

Grape berry moths lay eggs on flower clusters. The greenish or purplish larvae spin silver webs and feed on buds and flowers. Control grape berry moths with mating-disruption pheromone dispensers.

Many caterpillars can feed on grape leaves. Control by spraying Bt (*Bacillus thuringiensis*). Japanese beetles are fond of grapes. A few won't hurt the vine, but complete defoliation will.

Prevention and good housekeeping are the best ways to avoid disease problems. Mulch or cultivation will help prevent spores from splashing up from the soil and infecting new growth. Keep the area under the vine weed-free to increase air movement and reduce disease problems. Fungal diseases thrive in dark, humid environments, so arrange shoots in the leaf canopy so some light falls on all foliage. Cut off any leaves that are shading clusters. Remove infected parts immediately, and collect prunings and fallen leaves and dispose of them.

Sulfur dust or spray helps prevent disease. If you've had past problems with disease, you may want to consider a regular preventive spray program. Coat all parts of the vines, including the undersides of leaves, before symptoms appear. Apply when canes are 6, 12, and 18 inches long, then every two weeks until four to six weeks before harvest.

STRAWBERRIES

Fragaria x *ananassa*, *F. vesca*

Rosaceae

Strawberries are justly celebrated each spring in festivals all over America. Fresh strawberry shortcake, strawberry ice cream, strawberry pie, and even plain, red ripe strawberries are hard to beat. The plants are inexpensive, bear a full crop within a year of planting, and are relatively simple to grow.

Garden strawberry cultivars (*F.* x *ananassa*) are divided into three types: Junebearers, everbearers, and day-neutrals, which flower at different times in response to day length. Here's a rundown:

Junebearers: These bear fruit in June or July, or as early as April in Florida and California. They produce a single, large crop over three to four weeks. If you want to freeze lots of fruit at one time, plant Junebearers. There are early-, mid-, and late-season cultivars. Junebearers produce many runners and spread rapidly.

Everbearers: These produce a moderate crop in June, scattered berries in summer, and a small crop in late August. They are especially productive in northern areas with long summer days. The total harvest for everbearers is much less than the total harvest for Junebearers. Plant everbearers if you want berries for fresh eating all season. They produce fewer runners than Junebearers and so are easier to control.

Day-neutrals: These are unaffected by day length. They are extremely productive and bear fruit from June through frost in

northern areas, or January through August in milder climates. Unfortunately, day-neutrals require pampering. They are fragile and sensitive to heat, drought, and weed competition. If you are willing to give them the care they need, they'll reward you with a generous supply of berries throughout the season from relatively few plants. Day-neutrals produce few runners, so they rarely get out of control.

Alpine strawberries: Alpine strawberries (*F. vesca*) are one of the parent species of the garden strawberry. They produce small, aromatic berries from early summer through frost. Alpines are grown from seed or divisions and produce no runners. They are care-free and make good ornamental edgings.

Planting and Care

Plant strawberries in well-drained soil rich in organic matter. The ideal location is in full sun on high or sloping ground. Avoid frost-prone, low-lying areas.

To prevent diseases associated with overcrowding, allow a square foot of space for each plant. Choose one of three different planting systems: hill, matted row, or spaced runner. For a hill system, space plants 1 foot apart each way in double rows, with 2 to 3 feet between each double row. Remove every runner so plants channel their energy into producing large berries. Since plants are well spaced, the hill system minimizes diseases associated with crowding. For a matted-row system, space plants 1½ to 2 feet apart in rows 4 feet apart. Allow the runners and daughter plants to grow in all directions to form a wide, solid row. For the spaced-runner system, set plants closer than the matted row; remove all but a few runners. Pin down runner tips so daughter plants are about 8 inches apart in every direction.

Vigilant weed control is essential to prevent aggressive perennial weeds from out-competing shallow-rooted strawberry plants. It helps to lay down a thick mulch of straw around the plants during summer.

Even well-managed strawberries will decline after a few seasons. Start a fresh bed in a new site with new plants every few years. Renovate Junebearers each year right after harvest. Cut off and rake away leaves; dig out old, woody plants; and thin out remaining plants. Then fertilize and water.

Harvesting

Spring-planted Junebearers won't provide a harvest until a year after planting. Everbearers will produce a sizable late-summer crop, and day-neutrals will produce from midsummer through fall the year they're planted. Fall-planted berries will bear a full harvest the next growing season.

Harvest berries by pinching through the stem rather than pulling on the berry. Pick ripe berries every other day; always remove all ripe berries and any infected or malformed ones from the patch to prevent disease problems. During wet or humid weather, pick out diseased berries every day. Cull the moldy berries, wash your hands, and then pick the ripe berries. At the very least, carry a second basket or a plastic bag to put moldy or damaged berries in while you pick.

Strawberries need 1 inch of water per week throughout the growing season. Drip irrigation works best.

After the ground has frozen, cover the plants with fresh straw, pine boughs, or spun-bonded fabric to protect them from alternate freezing and thawing, which can heave plants from the soil. (In climates where a snow cover remains through the winter, strawberries need no special winter mulch.) Pull the mulch away from the plants in early spring so the ground can warm up. Reapply fresh mulch around the plants to smother early weed. Leave spun-bonded fabric on over winter and into spring for slightly earlier harvests. Remove it when flowers open so bees can pollinate the blossoms.

Preventing Problems

Verticillium wilt and red stele infect strawberry plant roots. They are often carried in on new plants and made worse by heavy, wet soil. Remove and destroy infected plants. Replant new plants in a new location or choose resistant cultivars. Vegetables like tomatoes and potatoes are also infected by Verticillium wilt, so grow only resistant cultivars where these vegetables have grown in the last three years, and vice versa.

Gray mold rots the berries. Wet, humid weather and overcrowded beds with poor air circulation invite it. Keep rows narrow, thin out crowded plants, and remove moldy berries from the plants immediately to control gray mold.

Berries injured by the tarnished plant bug don't grow or ripen properly, but remain small and woody or form hard, seedy tips.

Apples: A Strong Start

Vicki Mattern

Yes, you can grow apples organically! If you select disease-resistant varieties (see "Organic Apple Picks" on page 456) and handle your trees with care, problems should be minimal. When insect pests or diseases do show up, use organic controls such as those suggested in "Apple Pest Problem Solver." Here's how to get your apples off to a strong start:

1. **Choose the best rootstock.** First, be sure you have the best rootstock for your needs—dwarf, semi-dwarf, or standard. Each rootstock has its own advantages and disadvantages. For instance, trees with certain rootstocks may require staking, be less cold hardy, or have little resistance to fire blight and other diseases. Ask a local nursery, apple orchardist, or your county extension service to recommend the best rootstocks for your site and climate.

Continued →

2. **Plant it right.** Plant your apple trees in either early spring or fall. (Avoid fall planting if you live in a very cold region.) Choose a well-drained site that receives plenty of sunlight. If your soil is poor, amend the entire site—not just the planting hole—with compost and other organic materials, preferably the season before planting.

Organic Apple Picks

These reliable disease-resistant apple varieties are among the best for organic growing:

Early

'Pristine': large yellow fruit; sweet-tart flavor

'Redfree': medium-size red fruit; juicy, mild flavor

'William's Pride': large red fruit; crisp and juicy

Midseason

'Freedom': round, bright red fruit; crisp and tart

'Liberty': large, dark red fruit; crisp and juicy

'Prima': bright yellow with red blush; mildly tart

Late

'Enterprise': medium-to-large red fruit; rich, spicy flavor

'Goldrush': yellow fruit, sometimes blushed; spicy flavor improves in storage

Dig a generous-sized planting hole. Place some of the amended soil back in the hole so that the graft will be at least 6 inches above ground level. If you plant deeper, the graft could sink below the surface when the soil settles. Backfill the hole, then water the tree thoroughly.

Trees on dwarf rootstocks need staking to compensate for the vigorous roots. After planting, drive a sturdy wooden or metal stake into the ground near the tree. Tie the tree loosely to the stake. Wrap the trunk to protect it from sunscald, and install a hardware cloth sleeve to protect the trunk from rodents. Spread a layer of organic mulch over the area.

3. **Mulch matters.** Apply an organic mulch, such as straw, after planting an apple tree. Mulch helps the soil stay moist and blocks the growth of competing weeds and grasses, which could stunt the tree's growth. Keep the mulch about 2 feet away from the trunk of the tree, however, and remove the mulch in fall so that rodents don't move in for the winter.

4. **Feed lightly.** About 3 weeks after spring planting, spread a balanced organic fertilizer in a 2-foot radius around the base of the tree. Each year, spread 5 to 10 pounds of compost out to the drip line in late winter. Shoots on a well-nourished, young apple tree should grow 1 or 2 feet in a season; those on a mature, bearing tree should grow 6 to 10 inches. If growth is less than that, give them an inch or so of compost the following spring. If your tree fails to thrive, have a leaf analysis done through your extension service to identify any nutrient deficiencies.

5. **Train a leader.** Train the tree to a central leader—the main trunk—so that the interior of the growing tree has access to plenty of sunlight and air.

Year 1: After planting, prune the trunk back to 2 or 2½ feet. Also head back any side branches by one-third to one-half their length.

During the growing season, when the new growth reaches 1 to 1½ feet, choose three or four main branches spaced about 4 to 8 inches apart along the trunk. Cut off all other branches on the tree, but leave the central leader alone.

Year 2: The next winter or early spring, remove any new shoots that are growing at a narrow angle and competing with the central leader. Also remove any vertical side branches. Head

Apple Pest Problem Solver

Insect pests taking a bite out of your apple harvest? Here's how to manage them organically:

Mites, aphids, and scale. If you observed infestations of these pests last year, apply dormant-oil spray very early in the season, when a quarter-inch of green shows on the flower buds.

Codling moths. Reduce codling moth numbers by wrapping trunks with corrugated cardboard to attract larvae looking for a site to pupate. Remove and destroy the wraps one month after each generation of larvae begin moving down the trunk. When apples are about 2 inches across, slip small brown paper bags over them and staple shut. Spray several applications of Surround, a kaolin clay product, beginning at petal fall.

Apple maggots. Hang red, sticky ball traps from mid-June until harvest (one trap per dwarf tree and six per standard tree).

Plum curculios. At petal fall, spray Surround. Or, reduce damage by shaking trees daily for several weeks, knocking beetles onto a tarp, then drowning them in soapy water. Clean up all dropped fruits in June and again in fall.

back each branch tip by one-third to one-half to encourage side branches to form.

When the new growth is 1 or 1½ feet long, choose another "layer" of three or four main branches about 1½ feet above the previous branches and cut off any other new branches. The remaining branches should create a spiral pattern up the trunk so that each has access to the sun.

Year 3 and after: Repeat the pruning cuts from Year 2. Each year, focus your efforts on choosing the newest layer of main branches.

Fantastic Ways to Enjoy Your Fruitful Bounty

Vicki Mattern

Make the most of your fruit harvest with these two delicious recipes. Your hard work has never tasted this good!

Raspberries with Wild Rice

1½ cups defatted chicken stock

¼ cup wild rice

2 teaspoons canola oil

⅛ teaspoon dried marjoram

1 cup raspberries

2 tablespoons minced parsley

In a 1-quart saucepan, bring the stock to a boil. Transfer to the top of a double broiler. Add the wild rice, oil, and marjoram. Cover and cook over boiling water for 1 to 1½ hours, or until the liquid has been absorbed and the rice is tender. Transfer to a serving bowl. Fold in the raspberries and parsley.

Makes 4 servings.

Apples and Oats Breakfast Cereal

4 cups water

1⅓ cups oat bran

½ cup raisins

1 apple, shredded

1 tablespoon maple syrup

½ teaspoon ground caraway seeds

½ teaspoon ground cinnamon

1 to 2 cups skim milk

In a 2-quart saucepan, bring the water and oat bran to a vigorous boil, stirring constantly. Reduce the heat to low and cook for 2 minutes, stirring frequently, until thick. Remove from the heat and stir in the raisins, apples, maple syrup, caraway seeds, and cinnamon. Let stand for 5 minutes. Spoon into bowls and pour the milk over the cereal to serve.

Makes 4 servings.

Tips for Berries and Small Fruits

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

A morning of maintenance once or twice a year—and a watchful eye—are all the care blackberries and raspberries need. Other small fruits are even more obliging. Small fruits bear quickly and for many years, and they are perfect in the low-maintenance garden.

This section will help you choose berries and small fruits that will give you lots of delicious fruit for little or no care in return. You'll also learn tricks for keeping overzealous spreaders in check and quick ways to boost your harvests.

Grow Berries and Small Fruits the Easy Way

Berries and small fruits are tough characters. In the wild, they grow and bear quite happily with no help from anyone. Let them grow wild in your yard if you have room—you'll get plenty of handfuls of berries for your morning cereal. Here are four simple things you can do to civilize your berry patch and increase your harvests.

Mow. Your trusty lawn mower or string trimmer is a fast and easy way to keep the weeds from overwhelming your plants. Mowing also keeps adventuring berry suckers from turning your yard into an impenetrable briar patch. Leave a few inches unmowed around the main stems so you don't damage the plants themselves.

Mulch. Cover the no-mow zone right under your plants with mulch. Straw, old carpet (preferably natural fiber) spread upside down, or even the weeds you just uprooted from the front bed will do fine. If new weeds break through, just stomp them over and dump on more mulch.

Prune. You'll get plenty of fruit from most types of berries and small fruits even if you never snip a twig. But an occasional cut or two will keep plants vigorous, thin out dead wood, and keep the fruits within reach. Only you can decide whether saving time by not pruning is worth a smaller harvest or a struggle with a tangle of thorny canes. If you decide to prune, you'll find low-maintenance pruning tips for various fruits later in this chapter.

Feed and water. Mulching your plants with organic mulch like grass clippings, chopped leaves, or pulled weeds feeds them gradually, helps control weeds, and conserves soil moisture. If you care to do more, add compost under the plants each year as an extra feeding. Watering is optional, too. In dry seasons, if you don't water, the berries will be smaller or may even shrivel up before they ripen. If you aren't content with what nature can provide, keep the plants watered from the time they flower through harvest.

Just Starting Out? Put Your Berry Best Foot Forward

Get your berry plants off to a healthy start before you plant. You'll save yourself unnecessary maintenance later on.

Continued →

1. **Pick a berry good site.** Put your berries and small fruits where they will be happy. Like vegetables, they want as many hours of full sun as possible, well drained soil, and space so air can move around them.
2. **Banish pesky weeds.** It's lots easier to dig up or smother nasty perennial weeds before you plant; otherwise, you'll have to pick through a tangle of berry plants to get them out.
3. **Buy smart.** Don't be pennywise and dollar-dumb. Healthy, pest-resistant plants that are suited to your climate are a must for low-maintenance growing. To find out which types of small fruits and berries grow best in your area, call your local extension agent and ask what they have the fewest problems with. Select cultivars that are resistant to extremes (drought, cold, heat, humidity) and as many diseases as possible.

Buy plants (especially strawberries, raspberries, and blackberries) from a reputable nursery. Cheap plants are rarely a bargain in the long run and, like free plants from a neighbor, they can harbor diseases and pests.

Neglect These Care-Free Berries

It's really as easy as plant-'em-and-pick-'em with certain small fruits and unusual, delicious berries. You'll get loads of tasty fruits without pruning, staking, or other care. Here are some no-sweat possibilities.

Alpine strawberry (*Fragaria vesca* 'Alpine'). Compact plants without runners yield small, flavor-packed berries from spring through frost.

Bush cherries and native plums (*Prunus* spp.). Clouds of white flowers, then tart cherry-like fruit, cover these 3- to 10-foot bushes. Fall-bearing types thwart birds.

Currant and gooseberry (*Ribes* spp.). Tangy and translucent, red and white currants hang in clusters from 3- to 5-foot plants. Musky black currants dangle from bushes up to 7 feet tall. Try 'Crandall' for fragrant yellow spring flowers. Gooseberry fruits are larger, but the 3- to 5-foot bushes are quite thorny. Try 'Colossal' or 'Poorman' for fewer thorns.

Elderberry (*Sambucus* spp.) Clusters of creamy flowers as big as dinner plates on 5- to 10-foot stems mature into heavy crops of tart, flavorful berries.

Highbush cranberry (*Viburnum trilobum*). As much an ornamental as a fruit, these 6- to 10-foot beauties sport white spring flowers, reddish fall foliage, and tart red fruits for months.

Juneberry (*Amelanchier* spp.). Dainty white, early-spring flowers grace these shrubs and trees. The blueberry-like pink to purple-blue fruits are also attractive.

Mulberry (*Morus* spp.). While technically a tree, the fruits are definitely berries. Shake the lower branches over a sheet to quickly gather the ripe berries. Keep trees away from walkways—dropping fruits stain.

Put Your Berries Where Your Mouth Is

To save time and enjoy more berries, plant your berries and small fruits right next to your house or driveway. That way, you won't have to hike out to the back 40 to see if they're ripe or to pick a handful.

Sound unattractive? No way! Many berries and small fruits are very good-looking plants. Some have pretty, fragrant flowers and vibrant fall color. All you need to do is think of edibles instead of ornamentals when you plan your landscape. Here are some suggestions to get you started.

Groundcovers. Strawberries fill in fast as a groundcover on sunny slopes. Mix in some pink-flowered ones for interest.

Flower beds. Alpine strawberries are as pretty an edging plant as anyone could want, and they bear all summer. Try alternating yellow and red cultivars. Red currants drip clusters of eye-catching red jewels in season.

Vines for shade. Grape- or kiwi-covered arbors make for cool outdoor sitting.

Foundation shrubs. Blueberries and highbush cranberries look wonderful behind smaller plants. They offer spring flowers, tasty eats, and fall color—things many foundation shrubs don't rise to.

Don't Sweat It—Plant a New Strawberry Patch Every Few Years

Strawberry plants are cheap; your time isn't. If you have space for two strawberry beds in you garden, try this simple approach.

Plant a new patch. Every third spring, buy new plants and plant a brand-new strawberry patch. Put it as far away from the old patch as possible to reduce the chance of pests and diseases packing up and moving on over. Harvest the berries as they ripen.

Recycle the old patch. Bid the old patch goodbye as soon as it finishes bearing that same year. Till the old plants under or mow them short and spread mulch over them to kill them.

Plant Junebearers for Jam Sessions; Everbearers for Nibbling

Sun-warmed strawberries are one of the biggest pleasures of the home garden. But too many or too few berries aren't much fun. Select the right plants to start with to tailor your harvest.

Junebearers. These are the overachievers of the strawberry family. They make lots of runners and lots of berries all at once. If that's what you want, you just can't beat Junebearers. Choose a cultivar with multiple disease resistance.

Everbearers. These produce a few runners and a modest quantity of berries spread over the whole season. Pick an old-fashioned cultivar like 'Quinalt' or go with alpine strawberries. "Day-neutral" cultivars are not a good low-maintenance choice.

Give Crowded Strawberries a Haircut and a Dose of Old News

If you grow Junebearers, your plants may seem bent on crowding themselves out of existence. Compensate for this self-destructive trait by revving up your power mower for a once-a-year, done-before-you-know-it renovation.

Mow the tops and spread the news. After you harvest, set your mower at about 2 inches, snap on the grass catcher, and chop off all those leaves. Dump the clippings into the compost.

Cover the edges of the bed with sections of newspaper at least four sheets thick. Leave just a 6- to 10-inch-wide strip of mowed plants uncovered down the middle of the bed. Hold the paper down with handfuls of soil or compost.

Layer on compost, then mulch and water. Shovel a ½-inch layer of compost over the chopped-off plants in the unpapered strip. Then cover the whole bed (paper and compost-covered strip) with 2 inches of loose straw mulch. Finally, give the whole bed a good soaking, and you're done until next year.

Teach Your Blackberries and Raspberries to Stay Put

Blackberries and raspberries make great backyard fruit crops. Not only is their fruit delicious and abundant, the plants are also easy to grow. But they are generally thorny and can spread rampantly. Here are two things to do to make them welcome residents in your yard.

Give them enough room to start with. If you don't give blackberries and raspberries room at planting time, you'll curse them later as you try to squeeze around the plants to pick or mow. Plant raspberries and thorny blackberries 3 feet apart in a row. Plant thornless blackberries 6 feet apart in a row. Leave at least a 5-foot aisle between rows so you'll be able to get between them to mow and pick.

Show your brambles who's in charge. Curb the spreading tendencies of raspberries and blackberries right from the start. To make sure you end up with a manageable row, not an impenetrable scratchy patch, draw an imaginary 1-foot-wide strip with your new berries right down the middle. Mow the area outside that 1-foot-wide row regularly (seed it with slow-growing grass or let nature provide). Every time you mow you'll effortlessly nip off any suckers that sprout outside their designated row. No stooping, no sweat.

Take the "Ouch!" Out of Picking Bramble Fruits

If a thorny embrace isn't your idea of a good time, try one or more of these painless ideas.

Go thorn-free. Select cultivars with no or few thorns and avoid a sticky issue. Try 'Chester' or 'Navaho' for thorn-free blackberries. Boysenberries, Loganberries, and Youngberries all come in thornless versions, too. Look for 'Canby' or 'Mammoth Red' for almost thornless red raspberry harvests.

Stake it to 'em. Black raspberries and thornless blackberries don't spread much but stay in neat clumps. This is not to say they still don't try to reach out and grab you. Pound a metal fence post in right next to each clump. Tie the canes to the post with a sturdy loop of twine every year in late winter.

Round 'em up. Red and yellow raspberries spread underground to make a solid row (or patch if you let them). Avoid scratches from nodding canes with the easy-to-build V-trellis.

1. To make a V-trellis, pound pairs of 8-foot metal fence posts into the ground at an angle. They should be about 1½ to 2 feet apart at the bottom, 3½ feet apart at the top, and 6 feet high. You'll need one pair at each end of your row for rows up to 30 feet long.
2. Add a sturdy anchor post at either end of the row.
3. Use wire or plastic bailing twine to string the trellis. You'll need two wires, one 2½ feet and one 4½ feet from the ground.
4. Every year, cut off the canes that have fruited and tie the remaining canes loosely to the trellis in late winter.

Easy Pruning for Raspberries and Blackberries

Two or three short pruning sessions a year (depending on what kind of berries you have) is all it takes to tame your brambles. In return, you get easier picking with fewer scratches, and your plants will stay healthier.

SIMPLE SUMMER SNIPS

1. **Cut off used-up canes.** Bramble canes die after they make their summer fruit crop. So, after you harvest those last few fruits, pull out your trusty clippers. Clip off all the canes that had fruit on them as close to the ground as possible. Don't cut off canes that haven't made fruit yet; they hold next

Pruning for raspberries and blackberries

Continued ➔

year's berries-in-the-making. *Fall berry pickers take note:* If your red or yellow raspberries offer you fruit in late summer and fall, don't cut off those canes. They still have a summer crop of berries in them.

2. **Pinch back thornless blackberries and black raspberries.** Left alone, these types grow long, arching canes. Pinch them back when they're young and you'll get more fruit and suffer fewer entanglements. When the canes are about waist-high, snip off the top few inches. The clipped canes will grow many side branches that will bear lots of fruit next summer.

LATE-WINTER THINNING

On a nice day in late winter or early spring, spend a few minutes with your clippers in your berry patch. Start by cutting off any fruited-out canes you didn't remove after harvest last summer. Then cut off any skinny or bent-over canes. Finally, follow the appropriate set of instructions below.

3. **Red and yellow raspberries and thorny blackberries.** Thin the remaining canes to leave four canes per foot of row. Don't snip off the tips of the canes unless they were winter-killed.

4. **Black raspberries and thornless blackberries.** Thin the remaining canes to leave five canes per plant. Shorten each side branch to about a foot long.

Give Berry-Robbing Birds the Brush-Off

After weeks of watching them ripen, the last thing you want is bird-pecked berries. Try these tips for keeping the berries whole—and wholly for you.

Location. Plant near a door or path you use frequently. Human traffic discourages birds better than a scarecrow.

Tabby tracks. Entice a cat to lounge about in the berry patch. A puss in full view is a much more effective bird deterrent than a clever hunter hiding in the bushes.

Netting. Lightweight plastic netting keeps out birds (they will pick through it if it's too close to the fruit, though). Use a large piece and anchor it all around with boards or rocks so the winged thieves can't sneak under and have a feast. Or gather the edges around the base of a bush and tie it shut like a sack. Remove for harvest, then replace until next picking time.

Cage. Beat the netting blues by building a wooden cage frame with a door around the bush(es). Staple wire mesh or netting over it—it will last for years.

Train Grapes High and Let Gravity Do the Work

Gardeners often try to convince grapes to grow up a fence trellis, but vines don't always grow up. This means you spend your spare time tucking and tying stray shoots up all summer long. Use the following simple method and spend your summer lying down and sipping grapeade instead.

GETTING STARTED

1. **Build a sturdy frame.** You can build a long-lasting, one-vine trellis in just a few hours.

2. **Grow a tall trunk.** Plant your vine under the middle of the trellis. (Choose a hardy, disease-resistant cultivar suited to your area.) Tie a length of twine to the center of the top bar and tie the other end loosely near the base of the vine. Let the strongest shoot climb the twine. Remove any other shoots that form. Snip off the tip of the chosen shoot when it reaches the top bar.

3. **Grow two main branches.** Lots of side branches will sprout after you cut off the tip of the upright shoot. Choose two sturdy ones near the top bar. Tie them to the top bar, with one reaching in each direction. Snip off all the other side branches. Let your two chosen branches grow until they reach the ends of the top bar. Then clip off the tips.

GROWING HAPPILY EVER AFTER

1. **Do nothing all spring and summer.** As new shoots grow, their weight will pull them gently downward. Sit back and watch the fruit swell. Come fall, pick and enjoy. (And tell your friends how hard you worked to raise those grapes.)

2. **Do a winter haircut.** Get out your clippers on a sunny day in late winter and spend a few minutes getting your vine ready for spring. Check the ties that hold the main branches to the top bar and loosen or replace them as needed. Cut off any shoots that sprouted from the trunk below the top bar. Then cut all the hanging shoots back to leave two buds on each (the stubs will be about 4 inches long).

3. **Continue to grow happily ever after.** Alternate summer watching and winter pruning every year. As the vines age, cut off a few of the oldest stubs to thin things out.

CONVERTING AN OLD VINE

If you already have a grapevine, it's not hard to change it over to this training method.

1. **Check the support system.** If your vine already has a sturdy trellis with a wire 5 to 6 feet high, you can use that. If not, build one over the vine as described earlier.

2. **Hack it back.** Grapevines are very forgiving, so get out a saw and some clippers on a nice day in late winter and have at it. Cut your vine back to the top of the current trunk. Or, if the current trunk is badly twisted or lying on the ground, cut it off a few inches above the soil line. Next summer train one of the new shoots as you would a newly planted vine.

Oh-So-Simple Pruning for Blueberries

You can harvest good crops of blueberries for years without ever having to prune them. But, if you'd like to boost your crop a bit or think a bit of pruning is warranted, here's what to do.

This Berry Is for the Birds

Roger Yepsen

Read anything about growing elderberries, and you're apt to find a lot of grumbling about the way that birds manage to harvest the crop the day before the gardener gets around to it. You can try all sorts of stunts and devices to keep the birds away. Most practical is to toss netting over the shrubs until you're ready to pick. Or just stick a couple of plants in a relatively unused part of the yard and enjoy them and the wildlife they attract, without necessarily thinking of the elderberry pies and wine you might be making.

The plants are a bit straggly and free-growing, so they aren't the best choice for a tiny yard. Choose a site with moist, fertile, well-drained soil. Once plants are established, you can keep them vigorous by pruning 3-year-old canes. This encourages new growth and makes the overall form a little tidier.

An informal grouping of them won't attract much attention until the flowers appear—large, lacy umbrels of tiny cream-colored flowers. You can snip them for use in making fritters and pancakes, but you'll want to spare some in order to have berries. The inky berries find use in jam, pie, and wine. While the standard garden-variety elderberry remains popular, you have your choice of several that either offer generous harvests or add remarkable colors to the home landscape.

- 'Johns' is a selection of familiar native elderberry, *Sambucus canadensis*, chosen for its superior yield.
- 'Goldbeere' (*S. nigra*) produces stunning yellow berries.
- 'Black Beauty' (*S. nigra*) is just that, with purplish-black foliage setting off pink, lemon-scented blossoms.
- Variegated elderberry (*S. nigra*) has foliage patterned with cream and dark green.

Highbush and mid-high blueberries. Cut off a few branches that are 5 or more years old at ground level each winter. Also remove any dead branches or ones that are leaning severely.

Lowbush blueberries. These ground-hugging plants spread by suckers. The easiest way to prune them is to divide your patch in half and mow one half right down to the ground every winter. Alternate halves each year and you'll always have one patch busily growing back while the other patch is productively fruiting.

The Healthful Blueberry

Roger Yepsen

Blueberries aren't just for muffins and pancakes. Eaten frequently, they can have a range of beneficial health effects; in fact, in tests of some 40 fruits and vegetables, these little blue morsels ranked highest in antioxidants, including the anthocyanins responsible for their vivid color. And among blueberry varieties, 'Rubel' is a standout, with nearly double the antioxidant level. That doesn't mean they taste like vitamin pills. In fact, 'Rubel' has an excellent flavor. As a bonus, the small-size berries won't collapse in baked goods to leave the pockets created by super-size blueberries from the supermarket. 'Rubel' is a reliable producer, too, and although the small berries mean more picking, they are a relatively easy variety to harvest.

Blueberries in a Pot

Smaller blueberry varieties make handsome potted plants. And growing them in pots may be the way to go if you live in parts of the country with high-pH soils. To keep the soil cool and moist, it helps to dig a hole and sink the pot level with the ground. For the acid medium, mix ⅓ pine bark, ⅓ peat moss, and ⅓ potting soil. Stir in ½ ounce of sulfur for each cubic foot of soil. Fertilize with products labeled for use with azaleas. And top the pots with mulch to retain moisture and lower the temperature around the shallow roots. That's it—for the next 3 or 4 years. At that time, you'll want to replace the soil and prune back the roots, then repot.

Use a Vinegar Dressing for Sourer Soil

While there are a number of things you can do to lower the pH of soil or growing medium, the easiest way to treat potted plants or a few in the ground is to include vinegar when watering. Stir 2 tablespoons of distilled household vinegar into 1 gallon of water, and monitor the effect this has over time by testing the pH.

Plant an Edible Hedge and Throw Away Your Hedge Clippers

Need a hedge, but hate the repeated shearing it needs to stay neat? Wish you had room for some berry bushes, but can't figure out where to fit them in? Solve two problems with one

Continued →

low-maintenance solution: Replace your hedge with a closely spaced row of berries. Gooseberries or currants make a nice low hedge; thorny cultivars discourage trespassers. Blueberries or bush cherries make a taller, informal hedge. Raspberries and blackberries make a great narrow screen if you tie them to a fence.

Keep your hedge well back from driveways and sidewalks so dropped fruit won't land on the pavement. You may want to consult with your neighbors if the hedge will butt up against their property—offer them half the fruits, or plant away from the line and keep a mowed path along the actual property line to beat back wandering suckers.

The hardest part of herb gardening can be deciding what kind of herbs you want to grow—and then deciding where you're going to grow them. Do you want herbs for crafts or for cooking? Do you have sunny or shady sites? And what other plants grow well with herbs? Once you answer these questions, you'll be on your way to getting your herb garden off to a good start.

Herbs for Cooking

If you're just starting with herbs, or if you don't have a lot of garden space, you'll probably want to stick with basic culinary herbs. Homegrown herbs straight from the garden offer the freshest flavors—something you just can't get from store-bought herbs. It's also easy to dry herbs at home; their savory flavors will linger to add a taste of summer to midwinter meals.

A broad range of herbs is available to add flavor to everything from salad dressings to desserts. Here's a list of some popular herbs and how you can use them to liven up meals.

- Basil (with meats or vegetables, in sauces)
- Chervil (in soups or stews, or with fish or vegetables)
- Chives (in soups, salads, and sandwiches)
- Dill (with fish or vegetables; in salads or sauces; seeds used for pickling)
- French tarragon (in salads or sauces; with meats, fish, or vegetables)
- Garlic (with most anything, except desserts)
- Lovage (use like celery in soups, stews, salads, or sauces)
- Oregano (in sauces or with cheeses, eggs, meats, or vegetables)
- Parsley (with most anything, except desserts)
- Rosemary (with meats or vegetables; in soups or sauces)
- Sage (with eggs, poultry, or vegetables)
- Sweet marjoram (use like oregano)
- Thyme (with meats or vegetables)

HINTS FOR HERBAL COOKING

Fresh and dried homegrown herbs are interchangeable in most recipes. Dried herbs are more powerful, ounce for ounce, than fresh ones, so when substituting fresh herbs for dried, use two or three times more. To release the flavor of dried herbs, crush the foliage between your hands before adding it to recipes.

Most herbs don't require cooking; add them just before taking the dish off the stove. Or, for the freshest flavor, simply add a pinch of herbs to each plate at serving time. If you're using a specific herb for the first time, use restraint when adding it to a dish. If you overdo it, you might overwhelm the original flavor of the meat or vegetable that you meant to enhance.

If you do find that you've been a little heavy-handed with the seasoning, try these tips.

- Strain as much of the herbs and spices as possible out of the dish.
- Add a peeled, whole, raw potato to the pot just before serving.
- If possible, add more of the nonherb ingredients, or make a second, unseasoned batch of the recipe and combine it with the overseasoned one.
- Serve the dish chilled to blunt the taste of the overseasoning.

Herbs for Crafts

Making craft projects with herbs is a creative and delightful way to bring your garden indoors. You can work with fresh and dried herbs rich with color, texture, and fragrance to make wreaths, potpourris, and fragrant oils. The number of ways you can use herbs in crafts is really only limited by your imagination.

Many common herbs are great for craft projects. Here are a few ideas.

- Create a culinary wreath using chives, creeping sage, marjoram, oregano, or thyme.
- Braid fresh garlic heads together with bunches of herbs, then hang them to dry in the kitchen. Later, use scissors to cut away the bulbs or dried herbs as they're needed for cooking.

- Create a personalized potpourri by mixing together your favorite dried herbs, flowers, and spices. Mint, rosemary, sage, and thyme are just a few of the herbs that hold their fragrances well when dried.
- Use herbs like oregano and yarrow in fresh or dried arrangements.
- Instead of bows, add small bunches of dried and leafy herbs like thyme or sage to wrapped gifts.

Herbs for Fragrance

Flowers release their scents into the air so freely that you need only walk past roses, lilacs, or any other highly fragrant blooms to enjoy their aromas. Herbs, on the other hand, don't usually release their scents unless you rub a leaf, walk on the plant, or brush against the herb's branches. But that doesn't mean you can't grow and enjoy herbs specifically for their fragrances—and there are certainly enough fragrant herbs to choose from.

The leaves of scented geraniums, for instance, smell wonderful when you rub them. They come in a wide variety of scents, including ginger, lemon, lemon-rose, mint, nutmeg, and rose. Scented geraniums, along with lavender (floral scent), lemon balm (citrusy scent), lemon verbena (citrusy scent), and sweet woodruff (woodsy/earthy scent), are among the best-known herbs for fragrance.

You can use fragrant herbs many different ways, such as by creating these household items.

- Sachets
- Pomanders
- Herb pillows
- Essential oils
- Perfumes
- Scented candles
- Scented soaps

Herbs for Tea

Of all the things you can do with herbs, one of the most popular is making and drinking herbal tea. Historically, herbal teas were used as medicines, and many people still brew and drink them for their medicinal effects. But most people drink herbal teas because they find them soothing. You can brew a tasty pot from of any of the following herbs (use leaves only, unless otherwise noted):

- Angelica
- Bee balm
- Catnip (leaves and flowers)
- Chamomile (flowers)
- Lemon balm
- Lemon thyme
- Lemon verbena
- Mints
- Rosemary
- Sage
- Scented geraniums

Keep in mind that not all herbs are suitable for making tea. Do some research before you brew.

BREWING THE PERFECT POT OF TEA

Herbal teas are at their best when brewed lightly and delicately, and they can be made with either dried or fresh herbs. To make herbal tea, you'll need 1 teaspoon of dried herbs or 1 tablespoon of fresh herbs for each 6- to 8-ounce cup. Place the herbs in a china, pottery, or other nonmetal teapot (nonmetal pots help keep the tea pure in flavor and hot while it brews). Add boiling water and let the tea steep for 5 to 10 minutes (keep the pot covered to retain heat). Steeping time will vary, depending on what herbs you're using, so do taste checks at regular intervals until you're sure. Then strain the herbs out and serve the tea with honey, lemon, orange slices, or fresh herb sprigs.

MAKING ICED TEA

You can also make delicious iced tea using the same procedure as above, except use 3 tablespoons of fresh herbs or 2 tablespoons of dried herbs for each 6- to 8-ounce cup. (The extra amount of herbs will keep your tea from becoming diluted as the ice melts.)

For a change of pace, try freezing herb teas in ice cube trays and using the cubes to chill refreshing summer drinks, such as lemonade or punch—or to add sparkle to plain water. You can also freeze sprigs of herbs, like mint, in ice cubes for flavoring and decorating beverages.

Herbs for Healing

Herbs are also traditional ingredients in many home remedies. While natural food stores and vitamin suppliers sell all sorts of ready-made herbal medicines, it's less expensive and more satisfying to make your own remedies with herbs picked right from your garden. You can combine the herbs to fit your own needs and tastes and make just the right amounts you need. And by growing herbs organically, you can guarantee their purity because you'll know they won't have been treated with any chemicals.

Just remember that many herbs have toxic properties, and some are absolutely poisonous. That's why it's extremely important to

- make sure each plant is correctly identified before you use it;
- use all plants judiciously;
- remember that medicines that are healthful when taken in small quantities can be very harmful when taken in larger doses;
- avoid mixing herbal remedies with prescription medications; and
- consult a doctor about a serious ailment instead of trying to treat it yourself.

7 TOP HERBS

Here are seven herbs you can grow in your garden along with the conditions they cure.

Continued →

Basil wastes warts. This aromatic herb contains many antiviral compounds. One widely practiced folk remedy for warts involves rubbing crushed basil leaves on the growths.

Calendula treats cuts and scrapes. It reduces inflammation and heals wounds. The flowers are used externally in infusions (teas brewed for anywhere from 15 minutes to several hours), ointments, and tinctures.

Chamomile battles gingivitis. Chamomile is effective as a gargle or mouthwash for treating gingivitis. That's because its flowers contain several anti-inflammatory and antiseptic compounds.

Fennel eases asthma. The Greeks treated asthma and other respiratory ailments with fennel tea. Fennel contains a helpful chemical that helps loosen bronchial secretions.

Garlic relieves insect bites and stings. It contains enzymes that break down chemical substances that the body releases in response to pain. Interestingly enough, garlic works both internally and externally. You can make a poultice and apply it directly to insect bites and stings, or you can get a measure of relief by eating garlic.

Lemon balm alleviates migraines. The recommended dose is a tea made with 1 to 2 teaspoons of dried herb per cup of boiling water, steeped until cool.

Parsley beats bad breath. Bright green parsley is a rich source of chlorophyll, which is a powerful breath freshener.

Planning Your Herb Garden

Once you've decided what herbs you want to grow, you need to figure out where you're going to put them. If you just want to grow a few herbs, you may decide to tuck them into a flowerbed or the vegetable garden. If you really want to get into growing and using herbs, you'll probably want to create a separate garden for them. Either way, here are a few points to keep in mind.

MATCH PLANTS TO PLACE

For healthy, vigorous herbs, give your plants the best possible conditions. Although many herbs can adapt to poor, dry soil, that doesn't mean they thrive in it; fertile, well-prepared garden soil will encourage much better growth.

LEAVE ROOM TO GROW

Just like vegetables, herbs need room to spread without crowding their neighbors. For the right spacing, follow the guidelines on the seed packets or transplant labels. Crowding in lots of herbs won't give you a better harvest; instead, the plants won't grow as well, and you'll be left with lots of thinning and dividing work to keep plants healthy.

If you're growing perennial herbs that will spread—such as mint—plan some kind of containment system, or soon you'll have nothing but the spreaders. Or set aside a separate area of the garden where they can spread without endangering more delicate plants.

PICK A PRACTICAL SITE

While it's important to give your herbs the conditions they like, you'll also want to consider your needs. For example, you're most likely to use your herbs if they're close to the house. Also, plan your garden for easy care. You can do that by

- choosing a site near a water supply (for moisture-loving herbs like mint);
- allowing for paths so you can comfortably reach into all parts of the garden without stepping on the soil; and
- making at least one path wide enough so you can get into the center of a large garden with tools and a wheelbarrow.

COMPANION PLANTING

Companion planting is planting certain combinations of plants together to repel pests, attract beneficial insects, or make efficient use of garden beds. You can use herbs in companion plantings to repel or trap pests and to help other plants grow.

HERBS THAT BEAT PESTS

Try planting garlic with bush beans to repel aphids, and catnip with eggplant to repel flea beetles. A ring of chives under an apple tree is said to discourage apple scab. Other herbs used to repel pests include:

- Anise hyssop
- Borage
- Calendula
- Cilantro
- Dill
- Mint
- Rosemary
- Sage
- Scented geranium
- Tansy

You can also use herbs as traps to lure pests away from your crops. Dill and lovage can be used to lure hornworms from tomatoes, for example.

HERBS THAT HELP

Some herbs seem to enhance the growth of other plants. Try pairing borage with strawberries, chervil with radishes, sage with cabbage-family crops, and summer or winter savory with onions. Also try basil or thyme around tomatoes, and tarragon with any vegetable you're growing. (Watch out, though: Some herbs inhibit neighboring plants. Dill, for example, slows the growth of tomatoes, while garlic harms neighboring beans and peas.)

HOW TO USE COMPANIONS

You can mix and match herbs with most other plants, as long as you're meeting the growth requirements of each individual plant. Here are some guidelines to follow when choosing companions.

- Choose companion plants that have the same requirements for sunlight, water, season, and temperature.

- Plant perennial herbs with perennial crops. You can pair strawberries and Roman chamomile or lemon thyme in the same bed. Or let asparagus share space with tarragon. You can sow seeds of shallow-rooted annual herbs, such as cilantro or dill, around established perennial fruits and vegetables, but don't dig holes and set-in plants—you'll disturb the root system of the perennial.
- Avoid using invasive herbs, such as mint, as companion plants, because they'll quickly take over. Instead, grow invasive herbs in pots near the garden.

Planting an Herb Garden

Barbara W. Ellis

Herbs are among the easiest plants to grow in a garden—and the most useful. Perhaps best known for their role in cooking, where they add flavor to stews, soups, vinegars, jellies, relishes, and all types of recipes, herbs also have many other uses. They have been used medicinally and in cosmetics. In arts and crafts, they lend color and fragrance to potpourris, herb baths, wreaths, and sachets. However you use herbs in your garden, you'll find that they offer fragrance, flavor, color, a sense of history—and more.

Designing an Herb Garden

You can incorporate herbs in the garden in many different ways. Combine them with annuals and perennials in beds and borders. Plant them in a kitchen garden or perhaps a cutting garden. Grow a more traditional herb garden—perhaps in a formal knot pattern. Or simply tuck some commonly used cooking herbs in a half-barrel or a small bed outside the kitchen door so you can dash out quickly for an easy supply of fresh herbs.

The success of any good garden is based on the quality of the design and the implementation of that design. Take time before you plant to think about what herbs you want to grow, what you'll use them for, and what sites you have that would suit their cultural needs. For example, if you want a steady supply of fresh herbs for cooking, choose a convenient place for daily harvest. If you are growing a large supply for drying, on the other hand, convenience isn't such an issue.

STYLE

Select a style that complements the house or building nearest to the garden. Herb gardens are often used for historic sites because they can be used to represent almost any time period. A dooryard garden would be suitable for a colonial-style house. This informal style of herb garden, actually a type of cottage garden, provides a warm welcome to all visitors coming to the house. This style came to America with the early colonists and was primarily utilitarian. Herbs were planted near the front door for easy access; herbs such as tansy (*Tanacetum vulgare*) also had value in keeping insects out of the house.

A Victorian garden displaying herbs in containers or in flower beds is another possibility. Although the Victorians did not grow herbs in great quantity, there was some carryover from colonial gardens. They especially loved herbs used for fragrance, as well as those with special meaning. (Perhaps the best-known herb for this purpose is rosemary, for remembrance.) A garden using herbs in the Victorian style should include some of the Hybrid Perpetual roses that were so popular during the Victorian era and are a symbol of love.

Modern herb gardens tend to blend herbs with complementary plants. Herbs can create a lovely garden at the entrance to any house or building and can be blended beautifully with other plants, particularly old roses or perennials. At long last, herbs are being recognized as important ornamentals worthy of being grown in all types of gardens—formal or informal, historic or modern. Use herbs as border plants along walkways to soften harsh edges or in containers, on balconies, rooftops, or patios. There are limitless possibilities for the use of herbs in the landscape.

HERBS IN NOOKS AND CRANNIES

Although the subject of herb lawns is often covered in gardening books, using herbs in this manner generally works better in theory than in reality. Even in the finest of English gardens, an herb lawn is something that requires a great deal of work and considerable maintenance.

That said, if you still want the challenge of a thyme or chamomile lawn, plan on starting with plants rather than seeds to avoid severe weed competition. The two best plants to use are Roman chamomile (*Chamaemelum nobile*) and caraway thyme (*Thymus herba-barona*) because they are both durable and fragrant. Plant Roman chamomile on 6-inch centers in a moderately

Continued ➔

rich, well-drained soil. Be aware that Roman chamomile sometimes dies out in spots, leaving bare areas. Caraway thyme, on the other hand, is about the toughest herb for a lawn. It will create a thick, dark green mat within one year if planted in full sun in moderately rich, well-drained soil. Because the plants attract bees when in bloom, be sure to block off the lawn during their flowering time or prune back the blossoms. You'll need to water regularly until the plants become established.

Roman chamomile and caraway thyme are also excellent to use on benches constructed so that the seat is actually a bed in which plants are grown, a tradition in many European gardens. These and other herbs can also be included for planting in the nooks and crannies between rocks in a wall or along a walkway. Some are fine for rock gardens. The best of the very small thymes to grow in between bricks or stone on a walkway is mother-of-thyme (*Thymus praecox* subsp. *arcticus*), which comes in a red-, white-, or pink-flowered form. Again, it's best to begin with plants rather than seeds because it gets the planting off to a good, quick start. In fact, many herbs such as thymes are variable when grown from seed, producing many inferior hybrids. So it's best to avoid seed-grown plants altogether.

Other herbs to consider for use as groundcovers include sweet woodruff (*Asperula odorata*), which will grow well in moist shade; wild strawberry (*Fragaria virginiana*), which is perfect for a sunny spot in a naturalized garden; pennyroyal (*Mentha pulegium*), another sun-lover hardy only to Zone 7; and golden lemon thyme (*Thymus* x *citriodorus* 'Aureus'), a creeping thyme grown for its attractive golden foliage.

KNOT GARDENS

A traditional knot garden is another possibility for a small, formal herb planting. Knot gardens were at their peak of popularity in Elizabethan England, when it was fashionable to include a knot as an essential component of any garden. All knot gardens featured fragrant herbs, the clippings of which were used for scenting linens and fabrics. There are a variety of knot garden styles from which to choose. (One pattern is illustrated on page 500.)

Here are the main points to consider when thinking about and planning a knot garden.

- Place the garden where it can be viewed from above so the interlocking chains will be fully appreciated.
- Be sure the site has excellent drainage before you plant. If there is any doubt, either relocate the garden or consider adding a system of drain tiles.
- Select only plants that thrive in your area and that are completely hardy.
- Do not plan a large knot garden because when plants die, replacement plants are often hard to locate.
- Be sure to use plenty of evergreens so your knot will be interesting to look at in the winter as well as summer.
- Plan on pruning the plants in the knot from early spring through midsummer, as needed. Don't simply shear the surface of the plants each time. Plucking some of the branches near the center of the plant allows air and light into the center, which helps avoid serious disease problems and encourages new branches and thick growth.
- Use an attractive, appropriate material, such as cobblestone or brick, to edge the bed. The edging will help accentuate the design and perhaps help drainage.

Selecting a Site and Preparing the Garden

It's important to keep a few basic points in mind when selecting a site and planting your herb garden. With the exception of shade-loving herbs, most herbs require at least six hours of direct sunlight. The soil should be slightly acid, with a pH of approximately 6.5, and should be moderately rich and well drained. It also should be free of encroaching tree roots.

To prepare a new bed for herbs, follow the steps below. You'll have to make adjustments depending on your own garden and the conditions available.

Start by laying out the bed you've designed; ideally, you'll have a detailed design on paper to follow. Remove all sod or top growth from the site. Dig the soil either by double garden digging (going two spade depths into the soil) or digging as deep as possible with a garden fork. Then apply a generous amount of organic material over the top of the area; well-rotted manure and/or well-rotted leaves are best. Adjust the pH as necessary. If the soil is heavy clay, apply generous amounts of medium-size chicken grit because this will help to break up the heavy clay and improve aeration, especially important in wet winters. The addition of gypsum will help improve the drainage in heavy clay soils. If the area is extremely wet, consider making a raised bed to help improve the drainage. The best height for a raised bed is from 12 to 18 inches. Avoid higher beds, because the soil can become too dry in winter.

Planting and Caring for Herbs

Herbs are really no different than annuals, perennials, biennials, or bulbs when it comes to planting and propagation techniques. For planting, seed sowing, or propagation information, see the appropriate sections earlier in this book for directions.

The main consideration in keeping the herbs beautiful is to keep them well pruned. For the most part, herbs love to be cut back, and they will reward you with beautiful form and habit as long as their pruning requirements are met. With cooking herbs, of course, you'll want to use the trimmings in the kitchen. For best results, prune plants on a cool, shady day so that underlying growth is not suddenly exposed to hot, baking sun.

Planting & Caring for Herbs

Once you've decided what herbs you want to grow, it's time to get your hands into the soil. In this chapter, you'll learn what you need to do when starting with plants or seeds. You'll also discover how to control herbs that grow out of bounds and how you can keep herbs thriving indoors when Old Man Winter arrives.

Starting with Plants

Buying plants is the way to go if you want to start with just a few of each herb. Buying plants is also a good choice for perennial herbs. For the best success, buy the following herbs as plants (unless otherwise indicated):

- Garlic (bulbs)
- Mint
- Scented geranium
- Oregano
- Horseradish (roots)
- Rosemary
- Lavender
- Sage
- Lovage
- Tarragon
- Thyme

Start with only one or two plants to see how well they do in your conditions and how well you like them. You can always buy more plants next year.

SNIFFING BEFORE YOU BUY

Knowledgeable herb gardeners sniff before they buy. That's because many specialty herbs—including oregano and French tarragon—don't come true from seed. Seedlings may have no fragrance whatsoever, or they may only be a weak facsimile of the best culinary aromas. Don't buy plants hoping they'll develop fragrance and flavor as they grow because they won't. Even small plants should have the full-blown, pungent aromas the herbs are grown for. To test a plant's aroma, gently rub a leaf between your fingers and take a good whiff.

Starting from Seed

Growing herbs from seed is less expensive, but it takes more time and care than buying plants. As a general rule, growing from seed is best for annuals and biennials. It's also a good choice when you want more than just a plant or two. You can either directly sow herb seeds in the ground or sow them in pots indoors.

Herbs for direct sowing. You can sow these herbs directly in the garden: basil, borage, German chamomile, chervil, cilantro, dill, fennel, mustard, and parsley.

Herbs for indoor sowing. For an extra-early crop, start basil, sweet marjoram, and parsley indoors. For a continuous supply of fresh herbs, sow a second crop outdoors when soil temperatures warm up.

Easy perennials from seed. Catnip, chives, feverfew, and lemon balm are easy to grow from seed sown indoors or out.

Planting Herbs

Plant annual herbs just as you would plant vegetables. Since perennial herbs will grow in your garden for several years or more, take extra care to get them off to a good start. Plant them in spring or fall, when temperatures are cool and the soil has lots of moisture in it. Overcast days are best for planting because plants will have time to recover from the shock of moving from their cozy homes in pots to their new home in the garden.

Here's a three-step approach to getting your herbs in the ground.

1. **Prepare for planting.** Give your herbs a good drink before you plant by soaking them, pots and all, in a shallow tub of water, weak compost tea, or liquid seaweed solution. When you're ready to plant, pinch away any dead stems, leaves, and spent blossoms, and pull and throw away weed seedlings growing in the pot. Then dig a hole that's deep enough so you can set the plant at the same depth it grew at in the pot.
2. **Remove plants from pots.** To remove a plant from its pot, hold one hand over the top of the pot with your fingers around the stem. Turn the pot upside down with the other hand, and tap the bottom. Then gently squeeze the plant out of the pot while keeping the ball of soil and roots intact. Loosen roots that are tightly intertwined, and cut away bent or broken ones.
3. **Settle plants in the soil.** Center the plant in the hole, making sure it is sitting at the same depth that it was in the pot. Plants planted too deeply can rot; those planted too shallowly can dry out. After setting the plant, replace the soil. Firm the soil around the stems, forming a shallow trench around the center stem to hold water and direct it to the plant's roots. Water gently and thoroughly. Apply an organic mulch such as cocoa bean hulls to keep plant leaves clean and to help retain soil moisture.

Controlling Invasive Herbs

Some perennial herbs, such as horseradish and mint, grow so vigorously that they'll engulf their better-behaved neighbors. Here are some control tactics to use on them.

- **Impermeable mulch.** Mulch around invasive herbs with a 1-inch-thick layer of newspaper. Cover the newspaper with an attractive mulch like cocoa bean hulls or bark chips. Renew this mulch combination each season to prevent the spread of invasive herbs.
- **Herbal islands.** Plant invasive herbs in island beds, surrounded by lawn. Weekly mowing around the beds will keep the spreaders in check.

Continued →

- **Sunken containers.** Plant invasive herbs in large containers sunk into the soil to keep roots from spreading through the entire bed (see "Containing Creepers," below).

CONTAINING CREEPERS

If you plant an invasive herb in a bucket, the roots can't get through the bucket walls, and the bucket rim stops creeping stems that spread along the soil surface. (Trim away stems that sneak over the top.) Here's how to do it.

1. Use a hammer and nail to punch several drainage holes in the bottom of a large bucket. Five-gallon plastic buckets are ideal.
2. Dig a hole in the soil that fits the bucket. The hole should be deep enough so that when you put the bucket in the soil, the rim sticks up 3 to 4 inches above the soil surface.
3. Put the bucket in the hole and fill it with garden soil.
4. Plant the herb in the bucket, water thoroughly, and then mulch in and around the bucket to conceal its edge.

Preparing Perennials for Winter

With the end of the growing season in sight and colder weather right around the corner, it's time to start putting the garden to bed for winter. The first thing to do is stop harvesting perennial herbs in late summer or early fall, about 3 weeks before you expect the first frost. Once frosts arrive and the ground has frozen, mulch heavily to protect perennials from winter heaving (when alternate freezing and thawing of the soil pushes plants right out of the ground). When mulching, keep these points in mind.

- Straw is the ideal winter mulch. (You don't want to use leaves because they might drift over the crowns of small plants and suffocate them.)
- Draw the mulch up to, but not over, the plants.
- Gray-leaved plants that hold their leaves over winter, such as lavender and thyme, need additional protection in cold climates. Laying evergreen boughs over the plants will help ensure their survival with minimal dieback.

TENDER PERENNIALS

Tender perennial herbs, such as bay and rosemary, need protection in most parts of the United States. In zones where they're not hardy, grow them in containers and bring them indoors over winter. If you've been growing them in beds, you can still bring them indoors for the winter. Here's how.

1. Carefully dig up the plants and pot them.
2. Water the herbs and set them in a shady place outdoors for about a week, so they can gradually adjust to the dual shocks of pot culture and decreased sunlight. (If you're bringing herbs indoors that are already in pots, you'll still need to put them in shade for a week so they can adjust to the transition.)
3. Regularly check the plants, both outdoors and indoors, for pests such as whiteflies or aphids. If you find any, spray the plants with insecticidal soap.

The best time to pot most outdoor herbs is after the fall harvest and before the first frost. They should be safely indoors by the time frost strikes. Chives, however, benefit from induced dormancy before coming in from the cold. Divide the clumps, pot them, and let them stay outside until frost kills the foliage. Then bring them in, and they'll give you a new burst of lush growth.

Windowsill Herbs

Growing herbs indoors is a way to enjoy them all year long—particularly those herbs that wouldn't survive outdoors through the winter. No matter whether you decide to grow herbs as houseplants year-round or you're potting up perennials to move inside for the cold months, you'll give your plants an edge if you keep these points in mind.

Give them light. Most herbs thrive on at least 5 hours of sunlight a day. (Exceptions are the mints, parsley, rosemary, and thyme, which can take partial shade, and ginger and lemon balm, which actually like shade.)

Turn, turn, turn. Don't forget to turn the plants on windowsills regularly. Turning keeps them shapely and makes sure all sides get enough light.

Keep it cool. Most herbs like temperatures on the cool side—daytime temps of 65°F and nighttime temps of 60°F.

Give them air. Herbs are extremely sensitive to dry, stagnant air—which is what you probably have in your tightly sealed, centrally heated house. Stale air promotes fungal diseases and insect infestations. So try to keep the air moving around the plants by cracking a window in an adjoining room or by opening doors. Also, don't crowd the pots—give them plenty of space so air can circulate around them.

Mix things up. Herbs in pots need a reasonably rich soil mix with good drainage, such as 2 parts compost, 1 part vermiculite, and 1 part perlite. Or, try a mix of 1 part potting soil, 1 part sand, and 1 part peat moss.

Water regularly. Although herbs enjoy regular waterings, they're finicky plants—meaning that they don't like waterlogged soil. Water most herbs thoroughly when the soil surface starts drying out between waterings. But never let rosemary completely dry out, or else you'll inadvertently kill it. And always use room temperature water so you don't shock the plants' root systems.

Herbs in Containers

Herbs are great container plants, which means that you can grow them even if you don't have room for garden beds. Although

potted herbs won't produce the big harvests you'd reap from garden-grown herbs, a few pots in a sunny site will produce plenty of fresh herbs and some to dry, as well. And growing tender herbs such as rosemary in pots makes it easy to move them indoors for the winter.

CARE BASICS

Containers. When choosing containers for herbs, select those that have drainage holes. Also, make sure the containers are large enough to allow 1 to 2 inches of space around the rootball. If the plants become rootbound, move them to larger containers.

Potting mix. A good, organic potting mix is important for container plants.

Watering. You'll need to water herbs in containers more frequently than you would if they were growing in the garden. How often to water isn't rocket science, though. If you live where it's hot and dry, you'll need to water thoroughly and frequently. If you live where it's cool and wet, you'll need to water less often. (To check to see how moist the soil is, press your finger into the top inch of soil.)

Feeding. Herbs will benefit from a seasonal spray of liquid kelp or fish emulsion.

Herb Favorites

Now that you know the basics of growing herbs, it's time to decide which ones you want to try. In this section, you'll get an overview of 27 different herbs, as well as a few specifics for growing and harvesting each one. You'll also find out how you can use the herbs you plant for cooking, or—in some cases—healing.

BE CREATIVE

Remember that you can incorporate herbs into your flower or vegetable gardens; you don't have to grow a traditional "herb garden." And if you don't have room for a garden in your landscape, grow herbs in containers on your patio or inside on a windowsill. That's one of the great things about herbs: Because they demand little, you can grow them practically anywhere—from a simple arrangement of pots on a sunny porch to a stylized formal garden.

KEEP THEM CLOSE

Even if you use herbs in your garden beds, make sure you keep a few close to your kitchen door for the spur of the moment. After all, what could be more convenient than snipping a few sprigs of lemon balm for a cup of tea at the end of a hard day at work, or gathering some oregano to add to the simmering pot of freshly made tomato sauce on the stove?

BROADEN YOUR HORIZONS

Some of the herbs in this chapter, such as parsley, are probably familiar to you, while others, such as borage and feverfew, may be new. Experiment! Plant a couple of old standbys, and then broaden your horizons by trying one or two that you've never tasted before.

Angelica

(*Angelica archangelica*)

Angelica is a plant that stands out—literally—in any herb garden, as it can grow as high as 8 feet tall. This herb sort of looks like celery; it has a round, hollow stem that's purplish in color, and it has tiny white or greenish flowers. It's a biennial, or a short-lived perennial hardy in Zones 4 to 9.

GROWING GUIDELINES

Rich, moist, well-drained soil and partial shade are the keys to making angelica happy. Plant the seeds directly in the ground in spring, but don't cover them, because they need light to germinate. Once the seedlings are up, thin them so they're about 3 feet apart.

After frost of the first year, angelica will die back to the ground. The following year it will send up new shoots that you can harvest in early spring. If you let the seedheads develop, the plant will die after the seed ripens—but you'll get replacement plants from the seeds that have self-sown.

IN THE KITCHEN

Angelica has a slightly sweet flavor. Although you can use the leaves to dress up green salads, fruit soups, or meat stews, the most celebrated part of angelica is its stem. Cook the stems like celery and eat them as a side dish or add them to stews. You can also candy the stem and savor it alone, or use it to decorate

- cakes
- puddings
- tarts

HARVESTING HINTS

As mentioned earlier, you can harvest the stems (and leaves) in the spring of the second year of growth.

TRIVIA TIDBITS

In ancient times, angelica was supposed to ward off evil spirits and witches. Peasants would make necklaces of the leaves for their children to wear for protection. And the juice of the roots was used to make a special drink thought to ensure a long life.

Continued →

Anise Hyssop

(*Agastache foeniculum*)

Anise hyssop is a sturdy and lovely plant that's as much at home in the perennial border as it is in the herb garden. The stems rise up to 3 feet tall and are topped with 3- to 6-inch spikes of lavender-blue flowers from midsummer to early autumn. You'll see a lot of bees and butterflies buzzing around this beauty, seeking its rich nectar. The leaves and flowers have a slight licoricelike scent and flavor. Anise hyssop is a perennial that grows in Zones 4 to 9.

GROWING GUIDELINES

Although it prefers full sun, anise hyssop will also grow in light shade. A North American native, it's naturally found along lakeshores and streams in moist, well-drained soil that's very fertile.

You can buy young plants or start seeds indoors in late winter to transplant into the garden after the last spring frost—or you can sow the seeds directly in the garden a week before the last expected frost. Space seeds about 1 to 1½ feet apart. Even though anise hyssop is a perennial, the seedlings will usually reach blooming size the first year.

After a hard frost, the plants will die back to the ground. Be sure you mark the location of your plants, as they are very slow to emerge in the spring.

Plants do tend to be short-lived, so divide the clumps every year or two in spring to keep them vigorous. Even if the parent plants die out, you'll generally have plenty of self-sown volunteers to replace them.

IN THE KITCHEN

Fresh leaves are excellent in salads. Or, chop them and add them to summer fruit cups, along with the colorful flowers. The licorice flavor of fresh minced leaves is also a nice complement to

- chicken
- fish
- pork
- rice

Fresh and dried leaves make a good tea, alone or in combination with other herbs.

HARVESTING HINTS

For occasional use, snip off the leaves as needed, starting from the bottom of the plant.

The fresh flowers are attractive in salads and make a nice addition to potpourri. Cut them just as they begin to open.

For tea, cut the whole stems 4 to 5 inches from the base of the plant and strip the leaves off. To air-dry whole stems, gather them early in the day and hang them in a well-ventilated, dark, dry location.

TRIVIA TIDBITS

The botanical name *Agostoche foeniculum* refers to the many flower spikes on this fennel-like plant. It is just one of many unrelated plants that share the anise scent that is characteristic of fennel.

The Cheyenne called this herb "Elk-Mint" and made infusions of the leaves.

Basil

(*Ocimum basilicum*)

Basil's pungent flavor enhances any summer garden recipe. And you can choose from lots of varieties, including lemon, cinnamon, and anise-flavored types. Basil also comes in a variety of shapes and colors; you can plant varieties that are low-growing, stocky, or tall, with variegated, crinkled, purple, green, or smooth leaves. Basil is an annual that will grow in Zones 4 through 10. The plants can grow up to 2 feet tall and 8 inches wide.

IN THE KITCHEN

Basil has a rich and spicy, mildly peppery flavor, with a trace of mint and clove. For the best flavor, use basil fresh, rather than dried. Traditional in Italian, Mediterranean, and Thai cooking, basil is superb with

- tomatoes
- white beans
- pasta
- rice
- cheese
- eggs
- fish
- lamb
- poultry
- veal

You can also pair basil with a host of mild vegetables, such as zucchini, summer squash, and eggplant. If you make your own pizza or tomato sauce, try substituting basil for oregano and see how you like the taste.

GROWING GUIDELINES

You can grow basil in any well-drained soil amended with plenty of organic matter. Just make sure you plant basil where it will get full sun.

Start basil seeds indoors 6 weeks before your last expected frost. Plant the transplants outdoors after the danger of frost has passed and when soil temperature averages 50°F or higher. If you're growing small-leaved basil, place the plants

6 to 8 inches apart. Varieties with large leaves need 1 to 1½ feet between plants.

Mulching the area after the seedlings have shot up helps to keep the ground moist and warm and discourages weeds. But make sure you mulch after the ground has warmed up because basil roots need heat.

HARVESTING HINTS

Begin harvesting basil as soon as the plants have several pairs of leaves. If you harvest frequently, you'll help encourage your plants to produce new growth—which, in turn, will give you even more basil to harvest. You can keep harvesting basil up until the first frost. After harvesting, wrap dry foliage in paper towels and store it in resealable plastic bags in the fridge.

TRIVIA TIDBITS

In Italy, basil has been and still is a sign of love. According to tradition, if a man gives a woman a sprig of basil, she will fall in love with him and never leave him. Today, he'd probably have better luck if he made her pesto and served it over pasta with salad, bread, and a little wine—and then did the dishes afterward.

Borage

(*Borage officinalis*)

Borage produces blue, star-shaped blossoms and is a nice addition to a wildflower bed or vegetable patch, as well as to your herb garden. This annual, which can grow up to 2 feet tall and 16 inches wide, attracts lots of bees, which love its flowers.

GROWING GUIDELINES

Borage needs fairly rich, moist, light soil and full sun to grow. This herb is easy to grow from seed. Plant the seed as soon as the danger of frost has passed. (Borage will readily reseed itself after its initial planting.) When the seedlings poke their heads through the ground, thin them so they're about 2 feet apart.

Because borage likes moist soil, mulch around the plants to help contain moisture. Don't be disappointed if the pretty blue flowers don't appear on your new plants the first year; sometimes borage acts as a biennial.

IN THE KITCHEN

Borage has a crisp cucumber flavor. You can use the leaves raw, steamed, or sautéed, as you would spinach. You can eat the flowers and stems, too; peel, chop, and use the stems like celery. The leaves and stems enhance

- most vegetables
- green salads
- salad dressings
- pickles
- cheese
- fish
- poultry
- iced beverages

HARVESTING HINTS

Harvest borage as you need it for fresh use, gathering the young, tender leaves in the morning, after the dew has dried. Always use borage fresh because it loses its flavor and color when dried.

TRIVIA TIDBITS

Borage has a reputation for invoking courage. In fact, ancient Celtic warriors preparing for battle drank wine flavored with borage to give them courage. They believed their fears would vanish and they would feel elated. (The effect was probably due to the wine, not the borage.)

Catnip

(*Nepeta cataria*)

Catnip, which many people plant for their cat's enjoyment, is a member of the mint family. Cats love this feline drug, sniffing, chewing, and rolling around in it. (Humans, on the other hand, can only feel envy at all the feline fun.) Actually, smelling catnip—not

Continued →

eating it—is what does the trick for cats. A happy cat may chew on the plant, but that's mostly to bruise it and release more of the magic fragrance.

Catnip is coarse-leaved and gray-green, and it produces white flowers with purple-pink spots. A perennial, catnip can grow 1 to 3 feet tall and is hardy to Zone 3 or 4.

GROWING GUIDELINES

Catnip does best in average, sandy, well-drained soil, in an area that gets full sun to partial shade (although it will be most fragrant if you plant it in full sun). The easiest way to start a catnip patch is by planting a whole plant (check out your local garden center or ask a friend with an established patch if she has any extra plants).

HARVESTING HINTS

Gather the leaves and tops in late summer when the plant is in full bloom, and dry them in the shade. Store dried leaves away from moisture.

HEALING WITH CATNIP

Some people make a tea from the dried leaves and flowering heads as a remedy for upset stomachs and insomnia.

TRIVIA TIDBITS

During the Middle Ages, catnip was thought—incorrectly—to prevent leprosy.

Chamomile, German

(*Matricaria recutita*)

Chamomile, Roman

(*Chamaemelum nobile*)

Although you're probably familiar with the word *chamomile*, you may not know that it's two different plants. German chamomile is an annual reaching 2 to 3 feet tall. It has a honey-apple fragrance and is the chamomile commonly found in tea bags. Roman chamomile is a low-growing perennial that rarely reaches more than 9 inches high—making it suitable for use as a groundcover. It's hardy in Zones 6 to 9 and normally carries a stronger fragrance than its German counterpart.

GROWING GUIDELINES

German chamomile prefers sandy, well-drained soil, while Roman chamomile does best in light, dry soil. Plant both types in full sun to partial shade.

You can sow chamomile seeds outdoors in early spring or late summer by scattering them where you want them to grow in the garden. Don't cover the seeds with soil, though, because they need light to germinate. Keep the soil evenly moist (not soggy).

When the seedlings are 1 to 2 inches tall, thin them so that they're 8 to 12 inches apart. (For a groundcover, thin Roman chamomile seedlings to 4 inches apart.)

HARVESTING HINTS

If you're going to use chamomile for tea, harvest the flowers in full bloom throughout the summer. Spread the flowers thinly on a cloth or screen to dry in the shade. Throw away any stem or leaf parts, and store the flowers in an airtight container away from heat, light, and moisture.

HEALING WITH CHAMOMILE

Chamomile tea helps alleviate insomnia and calm nerves. It also relieves indigestion, nausea, and flatulence. A gargle with cooled tea helps relieve mouth inflammations and sore throats.

TRIVIA TIDBITS

In the days before refrigeration, immersing meat in chamomile tea was thought to help eliminate the rancid odor of spoilage. Chamomile was also reputed to make an excellent insect repellent. And the fresh, delicate fragrance of this daisylike herb made it a popular air freshener in homes where bathing was uncommon.

Chervil

(*Anthriscus cerefolium*)

Chervil comes in two main varieties, one plain and one curly. A hardy annual, chervil looks dainty and delicate and produces small white flowers on plants that can grow to 2 feet tall.

GROWING GUIDELINES

Chervil likes a rich, humusy, slightly acid soil. Plant it in early spring or fall, since it prefers cool temperatures and bolts (goes to seed) at the first sign of heat. You can direct-seed chervil shallowly in the ground. When the seedlings reach 2 inches high, thin them to 9 to 12 inches apart.

Keep mulch away from the bases of the plants, or they may be damaged by earwigs. Also, cover small seedlings with floating row covers to protect them from rabbits, groundhogs, or other animal pests.

IN THE KITCHEN

Chervil has a subtle, tender flavor—part anise, part parsley—and is an effective seasoning in food. You can use both the leaves and the stems in cooking, and whole sprigs make a delicate and decorative garnish. Chervil enhances

- carrots
- corn
- cream
- eggs
- fish and seafood (especially oysters)
- peas
- spinach
- veal

Chervil also complements tarragon, shallots, freshly ground black pepper, marjoram, and lemon. Always add chervil at the end of cooking because lengthy heating turns the flavor bitter.

HARVESTING HINTS

Snip the feathery leaves 6 to 8 weeks after sowing. Use chervil fresh because dried leaves have little flavor.

TRIVIA TIDBITS

Chervil's flavor and fragrance resemble that of the myrrh brought by the wise men to the baby Jesus. Because of this and because chervil symbolized new life, it became traditional to serve chervil soup on Holy Thursday.

Chives

(*Allium schoenoprasum*)

Chives are bulb plants, although the bulbs are so tiny that you might not realize they're there. Those plants produce beautiful, globelike, pink and lavender blossoms. A perennial, chives grow to about 18 inches high and thrive in Zones 3 to 9.

Growing Guidelines

This herb requires well-drained soil and full sun. The easiest way to grow chives is to start with young plants acquired from garden centers, by mail order, or from a friend. Plant clumps of up to six chive bulbs 5 to 8 inches apart.

Keep mulch away from the bases of the plants to improve air circulation and prevent disease problems. Chives compete poorly with other plants, so make sure to weed diligently.

You'll need to divide large clumps of chives about every 3 years. In early spring, dig up the plants and work the clumps apart with your fingers to create small clumps of four to six bulbs each. Then replant these divisions (or share them with friends).

IN THE KITCHEN

Chives taste like mild, sweet onions. Mince the fresh, slender leaves, and use them in recipes or as a garnish. French cooking combines chives with shallots, marjoram, and tarragon. Chives also complement

- artichokes
- asparagus
- carrots
- cauliflower
- corn
- onions
- peas
- potatoes
- spinach
- tomatoes
- cheese
- eggs
- fish and shellfish
- poultry

Don't overlook chive flowers, either. Toss them in salads or add them to a dish as a beautiful, edible garnish.

HARVESTING HINTS

Use scissors to cut chives about 2 inches above the soil. Before the plants flower in spring, harvest from the outside edges of the clumps. After the plants flower, cut back the entire plant to remove the spent flowerstalks. Chives are best if you use them fresh.

TRIVIA TIDBITS

Chives have been added to foods for nearly 5,000 years. Native to the Orient, they were probably first used by the Chinese and then the ancient Greeks. By the sixteenth century, they had also earned a place in European herb gardens. When the colonists came to America, they brought chives along with them.

Coriander

(*Coriandrum sativum*)

People have used coriander in cooking since ancient times. This cool-weather annual has pale mauve flowers that bees and other pollinators just love. (The flowers appear in spring or mid- to late summer, depending on when you sow them.) Those flowers produce seedpods that are harvested for the spice coriander. The lower leaves of the plant, commonly called cilantro, are round with slightly scalloped edges. Coriander grows 2 to 3 feet tall.

Continued →

GROWING GUIDELINES

Coriander prefers sunny sites with well-drained soil. Sow the seeds directly in the garden about ½ inch deep after the danger of frost has passed. After the seedlings appear, thin them to 4 inches apart and keep them evenly moist. Make sure you don't overfertilize this herb because too much nitrogen in the soil will produce a less-flavorful plant.

IN THE KITCHEN

Coriander leaves have a bold taste that combines a strong sage flavor with a sharp hint of citrus. You can mince the fresh leaves and add them to foods such as salsa, or you can use them whole as a lacy garnish.

Coriander seeds are sweetly aromatic, with a slight hint of citrus. Whole or ground seeds add character to

- salad dressings
- chili sauce
- guacamole
- marinades
- cheese
- eggs

The flavor of coriander also combines nicely with beets, onions, potatoes, clams, oysters, and sausage.

HARVESTING HINTS

Harvest fresh coriander leaves as needed. Coriander seeds ripen and scatter quickly, so cut the entire plant as soon as the leaves and flowers turn brown. Tie the plants in bundles, and hang them upside down with a paper bag tied securely around the flowerheads to catch the seeds as they dry.

TRIVIA TIDBITS

Greek and Roman doctors, including Hippocrates, made medicines from coriander, but it was also prized as a spice and as an ingredient in a Roman vinegar used to preserve meat. The Chinese used coriander as far back as the Han dynasty—207 B.C. to A.D. 220. At the time, it was thought that coriander had the power to make a person immortal.

Dill

(*Anethum graveolens*)

Dill is simple to grow and beautiful to look at, which is why you should add it to your garden. This annual herb grows in Zones 2 through 9 and looks like a smaller version of fennel, its relative. Dill can grow up to 3 feet tall and has pretty yellow flowers and feathery, blue-green leaves.

GROWING GUIDELINES

Dill needs moist soil with good drainage and full sun. This herb doesn't transplant well, so you'll have the best luck if you sow the seeds directly in the ground in spring, after the danger of frost has passed. (Make sure to weed diligently because small dill seedlings don't compete well against other plants.) When the seedlings are about 2 inches high, thin them so they're 10 to 12 inches apart. If you're growing dill mostly for the foliage, you can sow the seeds just 8 to 10 inches apart; do so every 3 weeks for a constant supply of dillweed.

If you're growing dill for the seeds, keep in mind that seeds may not be produced until the beginning of the plant's second year.

IN THE KITCHEN

Dill has a pickle flavor. You can use its feathery leaves fresh in salads and as garnishes; use the seeds whole or ground in longer-cooking recipes. Dill is delicious paired with fish (especially salmon), as well as

- cabbage
- cucumbers
- potatoes
- cheese
- cream
- eggs
- lamb
- pork
- poultry

Dillweed is easiest to handle when it's frozen on its stem. Simply snip some off with scissors as needed, and put the rest back in the freezer.

HARVESTING HINTS

Once the plants are well established (about 8 to 10 weeks after sowing), you can begin clipping the leaves close to the stem. You'll have to use it soon because dillweed will last only a couple of days in the refrigerator before it droops and loses its flavor. Or, you can freeze the freshly picked leaves.

Harvest the seeds when the flower matures, anywhere from 2 to 3 weeks after blossoming (the seeds will be a light brown color). When you cut the stems, make sure you leave enough of the stem on so that you can tie the plants into a bunch and hang them in a dark place for drying.

TRIVIA TIDBITS

The name dill comes from dilla, Norse for "to lull." Dill was believed to work as a charm against witches; mystics could combat an "evil eye" spell by carrying a bag of dried dill over the heart.

Fennel

(*Foeniculum vulgare*)

Fennel's filigreed leaves and small yellow flowers dance in the wind. This herb stands tall (about 4 feet high) to make a good border, or, when intermittently placed among shorter specimens, creates an unusual garden skyline. Fennel is a semihardy perennial, but most people grow it as an annual. It will grow in Zones 6 through 9.

GROWING GUIDELINES

You can plant fennel seeds directly in the ground as soon as you can work the soil in spring. Plant the seeds about 6 inches apart in a rich, well-drained bed that gets full sun. (Make sure to plant fennel away from coriander, which will prevent fennel's seeds from forming.) Cover the seeds shallowly and keep the soil moist. For a continuous crop of fennel during the growing season, keep planting seeds every 2 to 3 weeks. (Note: One or two plants will probably produce plenty of leaves for your family so you may want to succession sow only if you're growing extra for friends.)

IN THE KITCHEN

If you like the taste of licorice, then fennel is for you. Use fresh leaves in salads and as lacy garnishes; you can eat the tender stems like celery. Use the seeds, whole or ground, to dress up breads, cakes, and cookies. Fennel also goes well with

- beets
- potatoes
- pickles
- barley
- rice
- eggs
- cheese
- fish

The leaves and seeds lend aroma and flavor to herb butters, cheese spreads, and salad dressings.

HARVESTING HINTS

Begin snipping the leaves once the plant is well established—about 8 to 10 weeks after planting the seed. Then just keep harvesting the leaves as you need them.

If you want to harvest the seeds, you'll need to keep a close eye on the plants so you'll notice when the seeds turn from yellowish green to brown. When that happens, use scissors to snip the entire seedhead and let it drop into a paper bag. Store the bag in a warm, dark place for further drying. Once the seeds are thoroughly dried, store them in glass jars.

TRIVIA TIDBITS

In medieval times, people kept a stash of fennel seeds handy to nibble on through long church services and on fast days; the seeds were considered to be an appetite suppressant.

Feverfew

(*Chrysanthemum parthenium*)

A member of the daisy family, feverfew sports small, white flowers with yellow centers. This herb looks similar to chamomile; you can tell them apart because feverfew stands up straight, while chamomile tends to bend over. Feverfew is a short-lived perennial that's often grown as an annual. It grows 2 to 3 feet tall—making it perfect for defining garden borders—and is hardy in Zones 4 to 9.

GROWING GUIDELINES

Feverfew prefers full sun and well-drained soil. In spring, after the danger of frost has passed, sow the seeds by scattering them on top of prepared soil and lightly taking them in. Once the seedlings have germinated (they do so pretty quickly), thin them to 12 inches apart. (Be on guard, though—feverfew is a profuse self-seeder and may spread beyond your garden.)

HARVESTING HINTS

Harvest feverfew's leaves before the plant blooms in summer. Pinch back or shear off the tops of the stems. Dry the leaves by spreading them in a single layer on a cloth or screen in the shade. Store dried leaves in an airtight container away from heat and light.

HEALING WITH FEVERFEW

True to its name, feverfew reduces fevers (its common name comes from the Latin word *febrifugio*, or "fever reducer") and is a mild sedative. Modern research has also shown that the regular use of feverfew reduces the frequency and severity of migraines and associated symptoms, such as nausea and vomiting. In addition, the herb's anti-inflammatory qualities may provide relief to arthritis sufferers.

TRIVIA TIDBITS

In its long history, this herb has been used as an ingredient in making sweets and wines; as an aromatic to ward off disease; and as an insect repellent. It was also used to treat infant colic, vertigo, arthritis, kidney stones, and constipation.

Garlic

(*Allium sotivum*)

Garlic's aromatic bulbs are a seasoning and a vegetable in one. Soft-neck types have tops that flop over as they dry, so they're best for braiding. Hardneck garlic has a stiff upright flowerstalk (which can grow to 2 feet high). All types of garlic are perennials grown as annuals.

Continued ➔

GROWING GUIDELINES

Plant garlic in full sun in well-drained soil. You can plant in midfall or early spring as soon as the soil is workable. Although you can start garlic from bulbils, it's much faster and easier to plant cloves.

Set the cloves with the root end (the wider end) 1 to 2 inches deep, 6 to 8 inches apart. (If you're planting in fall, the cloves will produce shoots immediately, then become dormant until spring.) In spring, side-dress the plants with compost. Keep the soil evenly moist until the tops begin to die, then stop watering so the bulbs can mature.

IN THE KITCHEN

Garlic has a strong, oniony taste that livens up tomato sauce and pesto. (You can soften garlic's flavor by using it in recipes that require long, moist cooking, like stewing.) Other foods that are enhanced by garlic include

- cheese spreads
- herb butters
- herb vinegars
- pickles
- meat
- poultry

HARVESTING HINTS

Eventually, the tops of the garlic plants will begin to bend and turn brown. Garlic is ready to harvest when most (about 75 percent) of the leaves have turned brown. Pull fall-planted garlic in late June or early July; pull spring-planted garlic at the end of the season. Use a digging fork to lift garlic from the soil. Lay the whole plants in an airy, dark, dry spot for several weeks to cure. Then trim away leaves and brush off dirt.

Garlic keeps best if you store the bulbs in a cool, dark, dry spot.

TRIVIA TIDBITS

The Romans took garlic to strengthen them in battle because it was the "herb of Mars." (Mars was the Roman god of war.) European legend says that if a man chews on a garlic bulb during a footrace, no one will be able to get ahead of him. (And it's doubtful anyone would even want to draw close!)

Lavender

(*Lavandula angustifolia*)

Lavender has a classic fragrance that's reminiscent of days gone by—or at least of your grandma's house, where she had lavender sachets tucked into drawers. But despite its old-fashioned connotations, this perennial herb (it's hardy in Zones 5 to 8) is still quite popular today. And with good reason: Lavender smells great, works well in any garden setting (it can grow up to 30 inches tall), and has a myriad of uses.

GROWING GUIDELINES

This herb needs a sunny site with excellent drainage. (If your soil isn't well drained, you can amend it with compost and coarse gravel.) Lavender is difficult to start from seed because it needs a long time to germinate. So ask friends for cuttings or buy plants from your local garden center or from a mail-order supplier. Place plants 2 feet apart and water regularly for the next few weeks. Once established, though, lavender is very drought tolerant.

If you live in Zone 7 or colder, protect your lavender plants with a winter mulch of evergreen boughs to ensure strong new growth the following spring.

As it grows, lavender's stems can become woody. Keep your lavender looking its best by pruning it back by about half its height every 2 or 3 years in spring.

HARVESTING HINTS

If you're planning on drying lavender, harvest the flowers either when they first open or when they're full. To dry the flowers, spread them flat on paper or hang them in bunches in a warm, dry place, like an attic. Well-dried lavender flowers will remain aromatic for a long time.

HEALING WITH LAVENDER

In France and Spain, bruises and bites are treated with lavender compresses, while compresses of warm lavender tea are thought to relieve chest congestion.

TRIVIA TIDBITS

Up until World War I, lavender was used as a disinfectant for wounds.

Lemon Balm

(Melissa officinalis)

Brush this perennial herb's leaves and your fingers will smell of lemon with a hint of mint. Hardy in Zones 5 to 9, lemon balm produces tiny white or light blue flowers (much loved by bees) in May or June. The flowers bloom throughout the summer, and the plant grows to about 2 feet high.

GROWING GUIDELINES

Lemon balm isn't particular about soil or site (in fact, it can become invasive if left unattended). It prefers average soil in full sun, but will make do in partial shade. Sow seed directly in the ground about 12 to 24 inches apart in early spring or fall. When the plant becomes overgrown, dig up and divide the roots, then replant the divisions in either spring or fall.

IN THE KITCHEN

Fresh lemon balm leaves make a relaxing hot tea; you can also toss a few sprigs of lemon balm into cool summer punches or iced tea. In addition to beverages, toss whole or chopped fresh leaves into

- green salads
- marinated vegetables
- fruit salads
- poultry stuffing

Lemon balm also teams well with asparagus, beans, broccoli, corn, freshly ground black pepper, olives, lamb, and shellfish.

HARVESTING HINTS

If you want to use lemon balm immediately, pick the leaves at their peak of flavor and fragrance. For later use, harvest the leaves just before the plants begin to bloom, tie the stems in small bundles, and hang them in an airy spot out of direct sunlight to dry.

TRIVIA TIDBITS

The Greek physician Dioscorides put lemon balm on scorpion and dog bites, and then he would drop some more into wine for the patient to drink. And beekeepers used to rub lemon balm inside a hive to encourage a new swarm to stay.

Lemon Verbena

(Aloysia triphylla)

Lemon verbena is a deciduous woody shrub that has tiny lavender flowers and attractive foliage. Simply brush by this plant and you'll release its sweet, lemony fragrance. It's only hardy in Zones 9 and 10, but it works well as a container plant—which means you can still grow it if you live where winters are cold; you just have to bring it indoors. Lemon verbena grows 10 to 15 feet high outdoors in warm climates and up to 5 feet high in cooler climates or indoors. It flowers in late summer and fall.

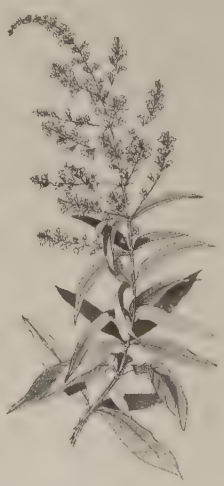
IN THE KITCHEN

Lemon verbena is most often used to make a delicately flavored tea. You can also use this herb wherever you want to add a touch of lemon, such as in rice, pound cake, or zucchini bread. Fresh or dried leaves also brighten the taste of

- vegetable marinades
- puddings
- salad dressings
- beverages
- fish
- poultry
- jams

Fresh lemon verbena leaves are tough, though, so be sure to remove them from marinades, beverages, and salad dressings before serving.

GROWING GUIDELINES



Unless you live in a very mild climate, you'll probably grow lemon verbena in a container. This plant does best in rich, moist (but not soggy) soil and full sun. Lemon verbena also likes a lot of nutrients, so feed your plant regularly with fish emulsion. (Remember: This herb is deciduous, so don't be concerned when it loses its leaves in fall.) Cut the plant back halfway in midsummer and again in the beginning of fall to keep it bushy.

You can take your container-grown lemon verbena outdoors during the warmer months. If you choose to expose your plant to the good life outside, make sure you place the container on top of a hard surface, such as tile or bricks. That way, the roots won't escape from the pot and take hold in the ground.

HARVESTING HINTS

You can harvest sprigs of lemon verbena leaves almost all year long.

Continued →

TRIVIA TIDBITS

Lemon verbena hasn't figured as an important medicinal herb, probably in part due to its late introduction to Europe (it's native to Chile and Argentina). It has, however, been used in folk medicine to aid digestion and to reduce fevers.

Lovage

(*Levisticum officinale*)

This perennial herb tastes like celery, but it is a lot easier to grow. The plant can reach 5 feet tall, making it a large, dramatic specimen for your garden. Another plus for lovage is its cold tolerance; it's hardy to Zone 3.

GROWING GUIDELINES

Lovage does best in moist, fertile, well-drained soil in a site that receives full sun to partial shade. Since you'll probably only want one lovage plant, purchase a seedling from your local nursery or ask a friend for a cutting. Whether you use seedlings or divisions, set them at least 2 feet apart. Wait 2 years before harvesting the roots or stems. Also, side-dress plants with a rich compost each spring, and keep them well watered during dry spells.

IN THE KITCHEN

As mentioned above, lovage leaves, stems, and seeds all taste like celery. You can use the leaves fresh in salads and fresh or dried in soups, stews, and sauces. Chop and add the stems to salads; you can also cook and puree them. The seeds, whole or ground, work well in pickling brines, cheese spreads, salads, salad dressings, and sauces. Lovage also enhances

- potatoes (especially potato salad)
- tomatoes
- steamed vegetables
- rice
- chicken
- poultry stuffings

HARVESTING HINTS

Gather seeds when the tiny fruits begin to open, which means they're ripe.

Cut the leaves or stems whenever you want to use them. To dry leaves and stems, hang them upside down in a warm, shady spot, like an attic. When dry, store the leaves and stems in tightly sealed, opaque containers because light will quickly yellow this herb.

TRIVIA TIDBITS

Lovage was very popular in the Middle Ages, when people grew it in kitchen gardens. Early herbalists recommended lovage as a diuretic, and occasionally as a cure for rheumatism, jaundice, malaria, sore throats, and kidney stones.

Marjoram

(*Origanum majorana*)

Marjoram is a gentle, subtly perfumed, calming herb whose fragrance livens recipes, potpourris, and other crafts. A tender perennial, marjoram will overwinter in Zones 9 and 10, but it is usually grown as an annual. It grows to about 1 foot tall.

GROWING GUIDELINES

This herb prefers full sun and light, well-drained soil. Because marjoram seeds are small and slow to germinate, you'll need to start them indoors 6 to 8 weeks before your last expected spring frost. When you transplant the plants to the garden, space them about 8 inches apart.

In the fall, dig plants and transfer them to containers for winter harvest indoors. Replant them again in spring.

IN THE KITCHEN

Marjoram tastes something like a mild oregano, with a hint of balsam. This herb is especially good with beef, roast poultry, green vegetables, eggs, potatoes, squash, and tomatoes. You can also add it to

- stews
- soups
- marinades
- stuffings
- dressings
- flavored vinegars and oils
- herb butters
- cheese spreads

Experiment and pair marjoram with other herbs, too. It complements basil, bay, garlic, onion, and thyme.

HARVESTING HINTS

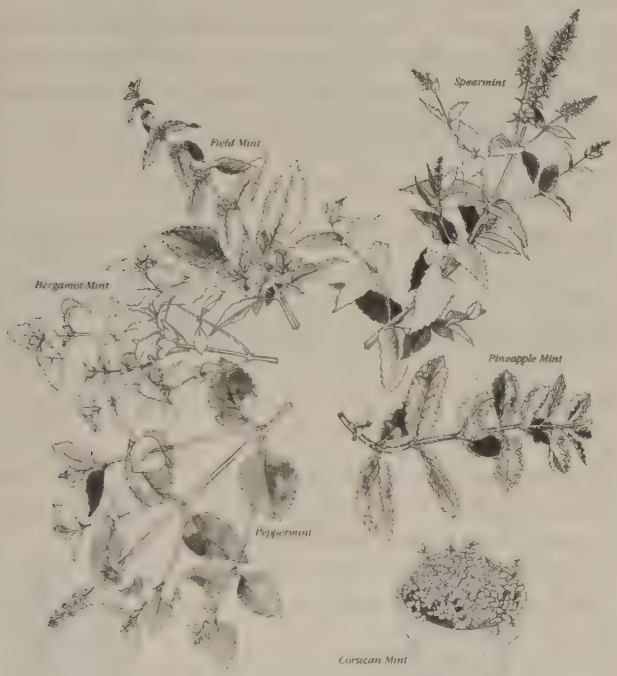
Begin harvesting marjoram 5 to 6 weeks after transplanting into your garden, or when the plants are growing vigorously. You can keep harvesting marjoram to use fresh as you need it. You might also want to dry some; unlike some other herbs, marjoram retains a lot of its flavor when dried. Dry it away from sunlight to preserve both color and flavor. When dried, rub the stems on a screen to shred the leaves, discard the stems, and store the shredded leaves in airtight containers.

TRIVIA TIDBITS

The Greeks called marjoram "joy of the mountains" and used it at weddings and funerals and to cure rheumatism.

Mints

(*Mentha* spp.)



Mint seems to be a good antidote to hot summer days, when you need something cool and refreshing from your garden. And when it comes to growing mint, you have a lot of flavors to choose from: apple, lemon, orange, pineapple, peppermint, and spearmint, to name just a few. Most mints are tough perennials, so they're easy herbs for beginners. They'll grow in Zones 5 to 9, and can reach up to 2 feet high.

GROWING GUIDELINES

Plant mints in full sun or partial shade in rich, moist, well-drained soil. Mint often doesn't come true from seed, so ask a friend for cuttings or visit your local garden center for seedlings.

Although mint is an easy herb to grow, it can spread aggressively—and then you'll have a difficult time getting rid of it. To prevent mint from spreading, plant it in 5-gallon containers with holes punched in the bottom for drainage.

Frequent cutting will keep mints at their prettiest. It encourages stems to branch out and makes for lusher, healthier plants. In late fall, after your final harvest, cut your mint plants to the ground. This eliminates overwintering sites for mint pests, such as spider mites and aphids.

HARVESTING HINTS

Fresh is best when it comes to mint. And because mint is such a tough plant, you can start harvesting it almost as soon as it comes up in spring. Harvest heavily and continuously to encourage new growth, then stop harvesting 2 to 4 weeks before fall frosts.

HEALING WITH MINT

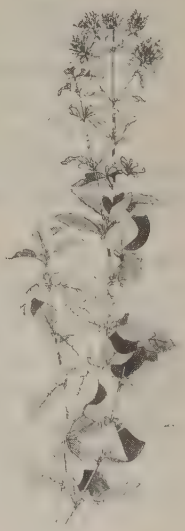
Of all the mints, peppermint is the one that has the most medicinal effects. You can use it to calm an upset stomach or relieve gas. Peppermint may also help relieve menstrual cramps.

TRIVIA TIDBITS

Beginning in the eighteenth century, mint became an important medicinal herb. Japanese mint was thought to aid fertility, while a remedy for mad dog bites called for combining peppermint or spearmint with salt and applying it to the wound.

Oregano

(*Origanum* spp.)



Tomatoes—and subsequently, tomato sauce—would only be half as popular without the biting flavor of oregano. This perennial herb is hardy in Zones 5 to 9 and grows to about 2 feet tall. Flavor varies with variety, so you might want to grow several different kinds to find the one (or two or three) that you like best.

GROWING GUIDELINES

Grow oregano in full sun and well-drained, rich garden soil. Starting with plants is probably the best way to grow this herb because seedlings vary in flavor. (Starting with plants also allows you to taste before planting.) Space the plants 1 to 2 feet apart, and keep mulch away from the stems to promote air circulation and prevent disease problems. Divide the plants every 3 to 5 years.

IN THE KITCHEN

Oregano has a hot, peppery flavor and enhances lots of food, including omelets, frittatas, and quiches. Oregano also adds dimension to

- eggplant
- marinated vegetables
- mushrooms
- beef
- onions
- pork
- potatoes
- poultry
- zucchini
- yeast breads
- roasted bell peppers

And, of course, oregano's flavor combines well with garlic, parsley, thyme, and olive oil.

Continued ➔

HARVESTING HINTS

You can harvest fresh leaves all season, as long as the plants are growing vigorously. Stop harvesting 2 to 4 weeks before the first expected frost; dry the remainder of your harvest so that you can enjoy the flavor of this herb all winter long.

TRIVIA TIDBITS

Many of oregano's early uses were medicinal, rather than culinary. For example, the Greeks made dressings from oregano leaves and placed them on sores and aching muscles, while some Roman scholars recommended oregano dressings for scorpion and spider bites. And after oregano was introduced to North America by European colonists, doctors used oil of oregano to help ease the pain of toothaches.

Parsley

(*Petroselinum crispum*)

Parsley really has a lot more to offer than just being the token garnish on a plate of steak or fish. This herb is an excellent addition to most recipes, is rich in vitamins and minerals (A, C, calcium, and iron), and fights bad breath (the chlorophyll it contains is a natural breath sweetener). Parsley is a biennial grown as an annual; it will grow in Zones 5 through 9. You can choose from two parsley varieties: curly leaf and flat-leaved.

GROWING GUIDELINES

Parsley grows best in rich, moist, well-drained soil in full sun to partial shade. Sow seeds outdoors when the soil temperature averages 50°F. You'll need some patience because parsley seed germinates extremely slowly, often requiring 6 weeks before the seedlings poke up through the soil. (You can speed germination by soaking the seeds in water overnight before planting.) Once the seedlings pop up, thin them to 8 to 10 inches apart.

IN THE KITCHEN

Parsley has a gentle flavor and works especially well at blending the flavors around it. You can use both the curly and flat-leaved varieties in cooking, although flat-leaf parsley is more flavorful. You can add parsley to most foods (except sweets), including

- salsa
- tabbouleh
- ham
- grilled meats
- poultry

HARVESTING HINTS

You can begin harvesting parsley as soon as the plants are growing vigorously. Snip individual outer stems from the plants; they'll continue to produce new growth all season long.

Parsley dries and freezes well. If you dry it, crush it by hand after it's completely dry and store it in an airtight container.

TRIVIA TIDBITS

In ancient Greece, parsley was used in funeral ceremonies and to make wreaths for graves. Parsley was also placed in wreaths given to winning athletes because the Greeks believed that the god Hercules had chosen parsley for his garlands.

Rosemary

(*Rosmarinus officinalis*)

Rosemary is an herb that's not just for the kitchen spice rack. You can use rosemary to make sachets for your drawers or a rinse for your hair. And rosemary oil adds a pleasant piney scent to soaps, creams, lotions, and toilet waters.

Rosemary grows in shrubby clumps of branching stems covered with wonderfully fragrant, needlelike, green leaves. This herb is a half-hardy perennial that's an evergreen in Zones 8 through 9. In Zones 6 and 7, you can grow the hardy variety 'Arp,' or you can grow rosemary as a container plant that's overwintered indoors.

Plants can reach 5 to 6 feet tall where they're hardy outdoors; container plants reach 1 to 3 feet tall.

IN THE KITCHEN

Rosemary is pungent and somewhat piney. Its flavor harmonizes with poultry, fish, lamb, beef, and pork—particularly when these foods are roasted. Gentle soups benefit from rosemary's robust character, as do marinades, salad dressings, and cream sauces. Rosemary also enhances

- mushrooms
- peas
- spinach
- squash
- tomatoes
- lentils
- cheese
- eggs

You can use both the flowers and the leaves for garnishing and cooking. Crush or mince the spiky leaves before sprinkling over or running into foods.

GROWING GUIDELINES

This aromatic herb grows best in well-drained, sandy, or gravelly soil and full sun. Seedlings grow very slowly, so you'll want to buy plants and start with them for fastest results. Space plants 1 to 2 feet apart (if you plan to grow your rosemary as a perennial in the garden, space the plants a good 4 feet apart).

HARVESTING HINTS

You can continuously harvest rosemary as long as the plants are growing. Strip the needles from the stems, then chop them before using. Rosemary also dries and freezes well. Freeze whole sprigs, and when you need some leaves, slide your thumb and index finger down a sprig, taking off as many leaves as you need.

TRIVIA TIDBITS

In ancient Greece, students wore rosemary garlands in their hair while studying for exams because they believed rosemary would help improve their memory. In the Middle Ages, men and women placed rosemary sprigs under their pillows to ward off demons and prevent bad dreams.

Sage

(*Salvia officinalis*)

If you can grow only one herb in your garden, you might want to make it sage. This shrubby perennial (about 2 feet tall) is an herb gardener's delight. The plants grow quickly without becoming invasive, and the flowers attract hummingbirds and beneficial insects. Sage is an intensely aromatic culinary herb that's hardy to Zone 5, but it will often survive in Zone 4 with winter protection.

GROWING GUIDELINES

Sage thrives in average, well-drained soil in full sun. You can buy plants or grow your own from seed. If you grow your own, start the seeds indoors 6 to 8 weeks before your last frost date. The seeds should germinate within 3 weeks at 60° to 70°F. Transplant the seedlings outdoors after all danger of frost has passed. Space the plants 18 to 24 inches apart in the garden.

IN THE KITCHEN

Sage leaves have a lemony, pungent taste and are the perfect complement to poultry, stuffings, and sausages, as well as

- artichokes
- asparagus
- eggplant
- onions
- potatoes
- squash
- tomatoes

You can add dried sage leaves to dishes, too. A bit of dried, crumpled sage, for example, perks up soft cheeses and lends an earthy tone to breads, especially flat breads like Italian focaccia.

HARVESTING HINTS

You can harvest sage leaves as long as the plants are actively growing. Sage leaves also dry and freeze well. To dry, snip the leaves from branches you've removed, discard the stems, and spread the leaves on cloth or paper in a dark, dry place. Store in an airtight container.

TRIVIA TIDBITS

Native Americans used sage as a medicine, mixing it with bear grease for a salve they claimed would cure skin sores. They also used sage as a leafy, disposable toothbrush.

Savory, Summer

(*Satureja hortensis*)

Summer savory is an annual that's highly aromatic and has been used to enhance the flavor of food for over 2,000 years. It has tiny white or pale pink flowers and grows to 1½ feet high.

GROWING GUIDELINES

This herb likes full sun and average soil and is easy to grow from seed. If you start summer savory from seed, keep in mind that it germinates quickly—so plan your planting accordingly. You can sow seeds no more than ½ inch deep in flats and transplant later, or plant directly into the garden. Space plants about 10 inches apart and keep them well weeded and well watered. If the plants start to flop over, mound soil slightly around their bases.

IN THE KITCHEN

Summer savory tastes like peppery thyme and blends well with most flavors, helping to bring them together. It's popular in teas, herb butters, and flavored vinegars, as well as with

Continued →

- asparagus
- garlic
- onions
- peas
- squash
- lentils
- soups
- eggs

This herb is also a nice accompaniment to fish. You can make a fish marinade by mincing fresh savory leaves and combining them with garlic, bay, and lemon juice. Or, add minced fresh savory to mayonnaise and serve it with poached fish.

HARVESTING HINTS

You can begin harvesting summer savory as soon as the plants get about 6 inches tall. If you keep snipping the tops of the branches, you'll be able to extend the harvest. When the plants insist on flowering, cut the whole plants and lay them on screening or paper in a warm, shady place. After they've dried (in a couple of days), strip the leaves from the stems and store the leaves in airtight jars. You can also collect the seeds as soon as they start to brown. Then place them in an airtight jar along with a desiccant (such as silica gel), and store the jar in a cool, dry place.

TRIVIA TIDBITS

The Romans used savory extensively in their cooking, often flavoring vinegars with it. And the poet Virgil suggested growing savory near beehives because of the pleasant-tasting honey it produced.

Scented Geraniums

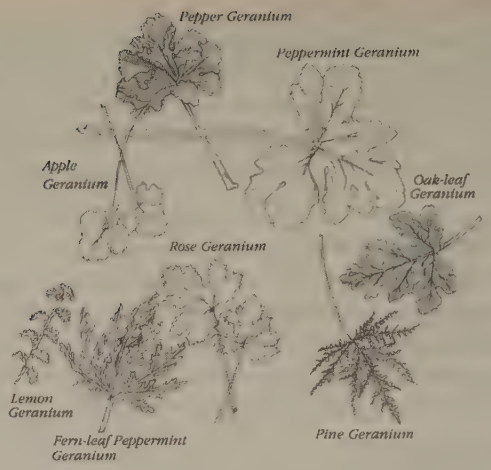
(*Pelargonium* spp.)

Apple, apricot, coconut, lemon, lime, peppermint, rose, strawberry—they sound like specialty lollipop flavors that you might find on a sweetshop counter. But these are just a few of the fragrances available in the amazing repertoire of scented geraniums.

These herbs aren't really geraniums at all, although their leaves look very similar to true geraniums. Scented geraniums are tender perennials that are hardy only in Zone 10. Some varieties can grow up to 3 feet high, while others are compact and work well in baskets. You can enjoy their fragrance in the garden, or dry the leaves and flowers to make sachets and potpourris.

GROWING GUIDELINES

You'll have the best success with scented geraniums if you start with plants or cuttings from a friend. If you choose cuttings, take them in spring or summer, using a sharp knife just below the node where a leaf grows from the stem. Place cuttings in clean sand, and allow enough space around them so that air can circulate freely. Keep them well watered (but not soggy), and in 2 to 3 weeks you should have little plants that you can transplant. Expose the plants to the outdoors only after the threat of frost is past.



IN THE KITCHEN

You can use the leaves of rose geraniums to flavor sugar. Simply alternate layers of sugar and leaves in a mason jar, and place the jar where it will catch the sun for about 2 weeks. Then sift the leaves out and you'll have rose-flavored sugar. You can also use some varieties of scented geraniums to flavor

- tea
- biscuits
- jelly
- pound cake

HARVESTING HINTS

Pick leaves just as the flowers begin to appear—preferably on a sunny, dry, day—for maximum oil content. Dry leaves in the shade to preserve their fragrance.

TRIVIA TIDBITS

Scented geraniums arrived in America during the colonial days and became popular rather quickly. Thomas Jefferson, in fact, brought several varieties to the White House with him.

Tarragon

(*Artemisia dracunculus* var. *sativa*)

Gardeners grow this aromatic, hardy perennial for its distinctively flavored leaves. Although tarragon isn't what most people would consider a visually stunning

plant, it's definitely worth growing because it's such a versatile culinary herb. Tarragon reaches 2 feet tall and will grow in Zones 4 through 8.

GROWING GUIDELINES

French tarragon needs full sun or partial shade and loose, rich, well-drained soil. Start by buying plants (French tarragon doesn't produce viable seed), or get divisions or cuttings from established herb gardens. Space the plants 1 to 2 feet apart. To get the best flavor from the foliage, remove the flower stems when they form. Divide plants every 3 to 5 years to keep them growing vigorously and to help them maintain their flavor.

IN THE KITCHEN

Tarragon offers a strong, unusual licorice flavor that stands out in cooked dishes. As a general rule, don't add this herb with a heavy hand, and don't cook it too long or else you'll bring out its bitter side. (For maximum flavor, add tarragon to long-cooking soups and stews during the last 15 minutes.) Just a few of the foods tarragon enhances are

- artichokes
- beef and pork
- leeks
- fish
- peas
- shellfish
- potatoes
- poultry
- rice

HARVESTING HINTS

Harvest the foliage continuously as long as the plants are actively growing. If you want to store fresh tarragon, freeze it or preserve it in white vinegar (tarragon doesn't dry well).

You can also use this herb in flavored vinegars, herbed butters, cream sauces, and soups and with cheeses, eggs, sour cream, and yogurt.

TRIVIA TIDBITS

Tarragon was thought to prevent fatigue, so pilgrims of the Middle Ages put sprigs of it in their shoes before beginning long trips on foot.

Thyme

(*Thymus vulgaris*)

Thyme is an incredibly useful herb. You can use it in recipes or as a cough suppressant; it attracts beneficial insects, like bees; and it grows just as well on a windowsill as it does in your garden beds.

This perennial herb will grow in Zones 5 through 9 and reaches about 1 foot high. Although thyme comes in both upright and prostrate forms, you should choose upright varieties

for using in cooking because low-growing types are often gritty with rain-splashed soil.

GROWING GUIDELINES

A well-drained site with sandy soil in full sun to partial shade is ideal for thyme. Because thyme seed is rarely true to type, your best bet is to start with plants or divisions. Space new plants 12 inches apart.

Once established, thyme is easy to keep looking good and producing well. Prune it lightly as needed to maintain its attractive shape.

IN THE KITCHEN

The bittersweet taste of thyme seems right for almost any dish, from vegetables and meats to soups and casseroles. Specifically, thyme works well with

- corn
- rice
- peas
- cheese
- sweet peppers
- eggs
- tomatoes

Its flavor also blends well with lemon, garlic, and basil.

HARVESTING HINTS

For fresh use, pick individual leaves or small sprigs as needed. If you want to dry thyme, strip the leaves from the stems and place them on a thin screen to dry before storing. Thyme also freezes well—just make sure you use an airtight container.

TRIVIA TIDBITS

From the fifteenth through the seventeenth centuries, thyme was used to combat the plagues that swept over Europe. And as recently as World War I, thyme's essential oil served as an antiseptic on the battlefields.

Herbs the Low-Maintenance Way

Barbara W. Ellis, Joan Benjamin, Deborah L. Martin

Herbs are naturals in your low-maintenance garden. Whatever your yard is like—hot and dry, or moist and shady—there are tough herbs just waiting to go to work for you. And herbs don't just stand around looking great—nothing puts life into food like your own freshly snipped herbs.

So stop struggling with finicky plants and set your sights on herbs instead. This section gives you some no-nonsense tips for succeeding with herbs and suggests specific herbs for challenging landscape sites. You'll also find suggestions for where to plant herbs for minimum maintenance and easy ways to start your own plants.

No-Nonsense Tips for Growing Herbs

It's hard to imagine plants that are easier to grow than herbs. All they ask for is six or more hours of sun per day and average to good garden soil, and they're on their way. Hardy perennial herbs, like garlic chives, mint, and thyme, are probably the easiest herbs to grow. Once planted, they come back year after year and eventually establish large attractive clumps. Annual herbs must be replanted each year but are well worth the effort. Use these tips to get your herb garden off to a great start.

Start with transplants. If you only need one or two plants (which is plenty for most herbs), transplants are your best bet. They'll have a head start on weeds, and you won't have to spend time thinning seedlings.

Well-drained soil means no-fuss herbs. If there's one key to growing healthy herbs, it's providing them with well-drained soil. Whatever type of soil you have, before you plant turn plenty of compost or other organic material into the planting site. Organic matter will improve drainage in waterlogged clay soils and hold water in sandy ones. You can also grow your herbs in raised beds or containers.

Hold the manure. Herbs don't need rich soil or fertilizer to grow well. In fact, too-rich soil just encourages rampant, less flavorful growth. A little compost mulch every few years is all the feeding most herbs require.

Use your herbs. Regular trimming keeps new tender growth coming, so clip all season. If you have more herbs than you can cook with, use the aromatic clippings as mulch.

Give perennials a fall haircut. Regular harvesting should take care of all the pruning perennial herbs need. If they look scraggly at the end of the season, cut them back by about a third and remove old or dead wood. Check again in spring and remove any dead wood. After three to five years, many perennial herbs lose vigor and should be divided or replaced.

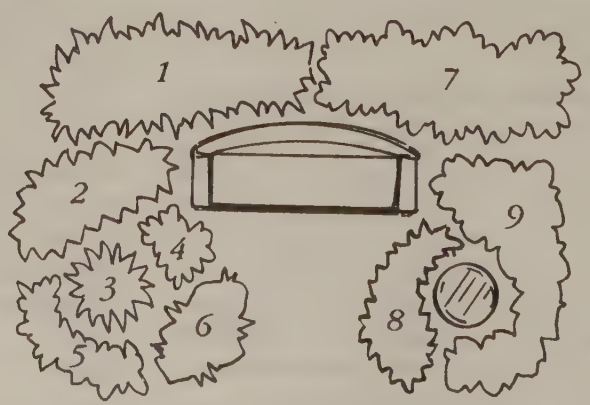
It Pays to Be Choosy When It Comes to Culinary Herbs

Not all herb plants are created equal. Use these suggestions so you don't get burned with a tasteless look-alike.

Grow from seeds. Annual herbs are easy to grow from seed, and you can expect good results from most any seed packet. Growing perennials from seed is more of a gamble; in general, it's easier and more reliable to start with transplants. Don't try to grow tarragon or oregano from seeds at all since these seed-grown plants are usually flavorless.

Sniff before you buy. Put potential purchases to the rub-'n'-sniff test. Rub a leaf between your fingers; if it doesn't have a good, strong aroma like the herb you're looking for, don't waste your time and money on it. This test also works for seedlings: When you thin, leave the most fragrant plants.

1. *Bee balm (Monarda didyma)*
2. *Rose geraniums*
3. *Purple sage*
4. *Lemon thyme*
5. *Parsley*
6. *Basil*
7. *Yarrow (Achillea x; 'Moonshine')*
8. *Garlic chives*
9. *Calendulas*



Buy smart. For the best selection, look for specialty growers in your area. Or order from one of the many mail-order herb nurseries.

Grow an Easy-Care, Elegant Herb Garden

A formal herb garden can take hours of fussing and trimming to keep it looking its best. With a little planning, you can keep all the elegance and eliminate all the work by trading in tightly clipped shapes for soft, natural ones. This garden features fragrant herbs that will stay neat and create waves of color with little or no pruning. To create your own fragrant refuge, select and arrange plants by height to create wavelike clumps.

This planting mixes annuals and perennials in a variety of heights and forms. Bee balm and yarrow provide a backdrop for the bench. Calendulas and garlic chives bloom under the birdbath, while rose geraniums, parsley, purple sage, lemon thyme, and piccola basil make a pleasant tapestry of color and form on the opposite side.

Don't Fuss with an Herb Garden—Grow Your Herbs with Vegetables

Why take care of two separate gardens when one will do? A super-easy way to grow annual herbs is to simply plant them in rows with your annual vegetables. There's room in most vegetable gardens for perennial herbs such as sage and chives, too: Plant them with your other perennial crops such as asparagus or rhubarb, away from the path of the tiller.

Plant a Drain Tile Herb Garden

Large ceramic drain tiles are great containers for herbs. Mix and match heights for a multi-tiered effect, or select all one height. Like any other type of container, they're a great way to grow herbs on a poorly drained site. Or consider planting invasive herbs such as mint in them to keep them out of everything else.

For best results, bury the base of each drain tile about 6 inches in the soil. For an easier and faster result with tiles under 1½ feet tall, just set the tiles directly on the soil. Be sure to level the site so each tile is stable.

Next, fill the tiles with potting mix and plant. Choose a mix designed for large containers or mix equal parts houseplant soil and perlite or vermiculite. Stir in a cup of compost per tile and water well to settle the potting mix. Leave 1 inch of headroom below the rim to make watering easy. Since containers dry out more quickly than inground plantings, water often so the mix never dries out. Monthly feeding with 2 tablespoons fish emulsion and 1 tablespoon seaweed per gallon of water will keep your drain tile garden growing strongly.

Simple Steps for Propagating Herbs

Propagating herbs is easy and rewarding, whether you need to divide a clump of herbs that's gotten too large or want to share a plant with a neighbor. For no-fuss propagation, stick to division and layering. Here's what you need to know to master these easy techniques.

Easy herb division. The best time to divide herbs is in early spring just before plants start to grow, but you can also wait until fall. To make replanting easier on your herbs, wait for a cloudy, windless day to work. Plants will be less stressed and will recover quickly. It helps to protect the newly divided plants from strong sunlight and provide extra water for a few days.

When you divide, dig up the entire clump with a garden fork or spade. Plants like oregano and mint form dense mats that are easiest to divide with a sharp shovel. For clump-forming herbs like chives, lift and water the clumps well. Then pull them apart with your hands and replant; each new clump should have three to five small bulbs to make a strong plant.

For an easy, no-dig approach to division, look for rooted sections around the edges of a clump, slice them off with a trowel, and pot them up or transplant them.

Layering. An easy way to root woody herbs like sage and lavender is to encourage them to form new roots through a process called layering. In early summer, select two or three branches near the base of the mother plant that are long enough to lay on the ground. Bend them over and strip the leaves off where the stems touch the soil. Press each stem firmly into the soil, anchor it with a U-shaped metal pin made from a piece of clothes hanger, and cover the pinned stem with soil. Keep the covering soil moist all season and you should have rooted plants to dig up, cut off the mother plant, and transplant in the fall.

Easy Ways to Hold on to Just-Picked Flavor

Stocking your kitchen with garden-fresh herbs for the winter doesn't have to take much of your precious time. Just use the tips below.

Strip the leaves later. Dry bunches of herbs through the season in a warm, dry place. Use rubber bands to bundle the bunches. Straightened-out paper clips make handy hangers for bundles. Stuff dry bunches of herbs into large airtight containers and label them. You can strip the herbs from the stalks in the fall when you have more time. To retain flavor, don't crumble the dried leaves until ready to use in cooking.

Make herb cubes for next-to-fresh flavor. Juicy leaves like basil freeze easier than they dry. Basil retains better flavor when it's frozen, too. To make herb cubes, puree leaves in the blender with enough water to make a slurry. Pour the slurry into ice cube trays and freeze. Pop out the cubes and store in plastic bags. Add herb cubes to soups and stews as needed.

Freeze leaves whole for fast flavor. If you're really short of time, strip leaves from stems, pack them in self-closing bags, and freeze. Be sure to label frozen herbs—they'll all look the same once they're frozen.

Continued →

Quick and Tasty Salads

Herbs look as good as they taste, so why hide them in the backyard? For an ornamental and edible salad bar right outside your door, try growing sage, garlic chives, basil, marjoram, tarragon, and other herbs next to greens like lettuce, chard, and arugula.

Edible flowers such as nasturtiums add color to the design—and your salads, too. To make your garden as convenient as it is attractive, choose a handy location, such as just outside the front door. That way you can easily step outside and harvest salad greens and herbs just minutes before mealtime.

Sit Back and Watch These Herbs Plant Themselves

Instead of direct seeding, thinning and fussing every year, let herbs replant themselves. Plant them once in an out-of-the-way place and each year let some of the flowers go to seed.

To get your reseeding patch started, wait until the soil warms up and prepare a seedbed outdoors where the plants are to grow. Then sow the seed and keep the area moist until the seeds pop up.

Each year, let some of the plants go to seed for a crop in fall and/or the following spring. Don't pile a lot of mulch over the seeds or they won't germinate when the weather cools off in late summer. This technique is also good for fussy herbs like angelica that only grow from just-ripened seed.

Cooking with Herbs

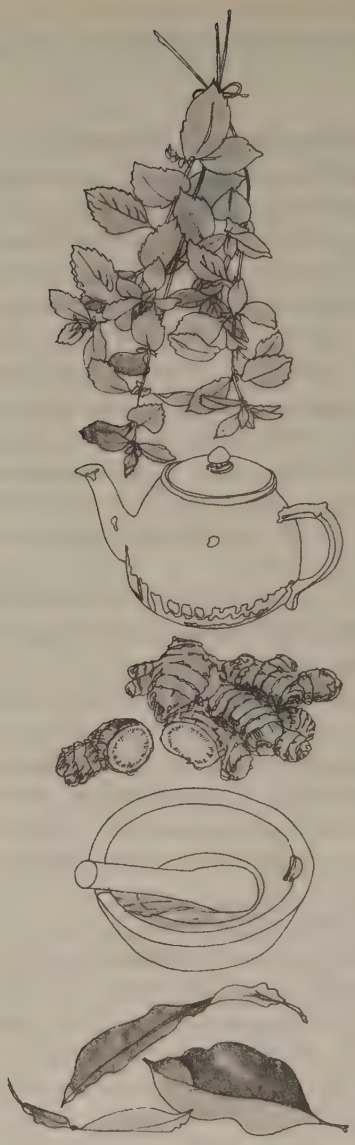
Claire Kowalchik and William H. Hylton

If the secret to your favorite recipe for tomato sauce is a predominance of basil and your neighbor swears only by oregano, which recipe is correct? Both, of course, because the seasoning and flavoring of food with herbs and spices is mostly a matter of personal taste. We choose harmonious flavors by tasting and smelling as we cook. The choice between basil and oregano can depend on the sweetness of the tomatoes; whether they're fresh, frozen, or canned; if the sauce will be served hot or cold; what food will be served with the sauce; and what sort of mood you're in.

So if seasoning is in the taste buds of the beholder, why bother at all with a culinary section? Because of basics. By acquainting yourself with or refreshing your knowledge of how to use herbs, classic combinations, storage methods, and individual flavor personalities, you'll become a more skillful and creative cook.

General Techniques and Preservation

The following tips and suggestions shouldn't be regarded as the last word on using herbs in cooking. Be sure to check the entries on individual herbs for additional ideas and tips.



Using fresh herbs: Some say it started in California at restaurants like Spago and Chez Panisse. New Yorkers claim it began in the Village and spread from there, and others say James Beard had been doing it for years.

Regardless of where it started, any red-blooded lover of food has realized that there's a new culinary aroma in the air, and that aroma is herbal. In restaurants, markets, and in the home, fresh herbs are becoming commonplace. They're being sprinkled, pureed, and sautéed with everything from appetizers to desserts.

In fact, in many recipes, fresh herbs are taking center stage. For instance, press fresh marjoram into the flesh of fish before a quick grilling and the beautiful pattern, aroma, and taste that the marjoram offers will outperform any sauce.

Or think of pesto, the popular herb paste. We used to make it for pasta and only when we could gather enough fresh basil. Now we create pestos with oregano, dill, or coriander leaf and the medium with which we use them (chicken, fish, pasta, or vegetables) gets second billing.

Because fresh herbs are inspiring, they will continue to sprout up in a variety of recipes and cooking styles. And because cooking is an ongoing, creative process, fresh herbs will continue to be enjoyed by a growing and eager audience.

Grating, Grinding, and Crushing

An electric spice grinder is very handy for grinding whole spices. Small spice graters for whole nutmeg or allspice are useful and also come in handy for grating lemon and orange peel. For crushing herbs and spices and blending them into other ingredients, a mortar and pestle are very efficient.

If you use a blender to grind spices and herbs, try this method: A pint canning jar with a standard-size mouth will fit perfectly into many blender bases. Just put the spices in the jar, place the blade, rubber, and screw bottom of the blender container onto the jar as you would a lid. Turn the jar upside down, place in the blender base, and proceed with grinding the spices.

To serve four people with a sauce, soup, stew, or sauté, use about 2 teaspoons of minced fresh herbs. To reach the fullest aroma, rub the leaves between your hands, then mince them using a sharp knife or by snipping them with kitchen shears. Mince large amounts of herbs in a food processor.

Whole fresh leaves should be rubbed between your hands before adding to marinades, soups, stews, and punches. The amount of leaves to add will vary depending on their size, but use the 2-teaspoons-for-4-servings rule and try to visualize how many whole leaves will make that amount.

For the best flavor in long-cooking foods like soups and stews, add fresh herbs during the last 20 minutes or so of cooking.

Conversely, fresh herbs may not have a chance to release their flavors in uncooked foods like salad dressings and marinades or during microwaving. Be sure to taste these foods before serving since it may be necessary to add more herbs.

Tips for keeping fresh herbs fresh: Bouquets of fresh herbs can be set into jars filled with an inch or two of water, covered loosely with plastic wrap, and refrigerated. They'll last this way for about two weeks.

Smaller sprigs of herbs should be wrapped in paper towels, sealed in plastic bags, and placed in the crisper drawer of the refrigerator, where they'll last for about two weeks. Be sure the leaves are completely dry, or brown spots may develop.

Using dried herbs: Although this is the most common condition for culinary herbs, the common *collection* is changing. Where once our staples were bay leaves, dried oregano, and cinnamon, our culinary exploration is encouraging us to reach out.

We now own saffron for our fiestas and file for our gumbos. Dried seeds like coriander and cardamom and dried roots like ginger and horseradish are now the norm for the well-stocked, creative cupboard.

Herbs preserve most flavorfully when they're picked (1) before they flower, and (2) early in the morning just after the dew has dried. Always use plants that are healthy and free from dark spots and other imperfections.

Generally use about 1 teaspoon of dried herbs to serve four people, or about half the amount you would use of fresh. Smell the herbs before using them to make sure they're aromatic. Then rub them between your hands or grind them coarsely in a spice grinder, coffee grinder, or with a mortar and pestle. Use them immediately. Dried herbs can also be steeped in warm stock or other liquid, to cover, before adding them to recipes. This will enhance their flavors. Remember to taste, and, if necessary, adjust the flavor before serving.

Tips for drying herbs: Herbs may, of course, be dried in commercial dryers. But if you don't have one, there are lots of alternatives. For starters, use your oven on its lowest setting. Spread the herbs on cookie sheets, set the sheets in the oven, and leave the oven door ajar to help encourage circulation. Stir and check the herbs occasionally. They're dry when the leaves crumble when pinched and rubbed.

Bouquets of herbs can be hung to dry. Choose an airy, dry place like an attic, and hang the herbs upside down. Tie a paper bag over the bouquet to keep it from the light and to catch falling herbs. The bouquet may take up to two weeks to dry, but check its progress daily.

Microwaving is another alternative. Start with a clear, sunny day, because in humid weather the herbs may reabsorb moisture when removed from the microwave. Brush soil from the leaves and stems with a stiff paintbrush. Then place about a cup of herbs in a single layer between paper towels, and microwave on high for about three minutes. (Delicate herbs like thyme should be turned every 30 seconds.) If the herbs aren't completely dry after three minutes, reset the timer for 20 seconds, and start the microwave again. Don't let the herbs get too hot, or they'll taste scorched. They're ready when they feel brittle and rattle when you shake the paper towels, or when the leaves pull easily from the stem.

Herbs like parsley, coriander leaf, and rosemary dry well in the refrigerator. Simply place an unwashed bouquet in a paper (not plastic) bag. Close the bag and leave it in the refrigerator for about a month. The bouquet will be surprisingly green, but dry and aromatic.

What Herbs Go Best With...

The question usually comes up just after "What's for dinner?" While it is true that most herbs go with most foods, there are some pairings that are especially successful. Listed below are common foods and some of the herbs that best flatter them. While the table isn't the final word, it can be a starting point for your own culinary experiments.

Asparagus
Chives
Lemon balm
Sage
Savory
Tarragon
Thyme

Beans, dried
Cumin
Garlic
Mint
Onions
Oregano
Parsley
Sage
Savory
Thyme

Beans, green
Basil
Caraway
Clove
Dill
Oregano
Mint
Sage
Savory
Thyme

Beef
Basil
Bay leaf
Caraway
Cumin
Fenugreek
Garlic
Ginger
Marjoram
Onion
Oregano
Parsley
Rosemary

To store herbs, remove the leaves from the stems. Make sure they're completely dry, or mold could occur. Then scoop the herbs into tightly covered glass jars away from the light and heat, and they'll be flavorful for about a year. Don't make the easy mistake of storing them above or next to your stove, for the heat will dissipate their flavors.

Roots and thick stems can be dried in a commercial dryer, your oven, or a microwave. For faster drying, chop them into pieces first. Store them in tightly covered glass jars away from the light and heat, and always try to grind them as you need them, using a coffee grinder, spice grinder, or mortar and pestle.

To dry seeds, gather ripe flower heads and lay them out in an airy, dry, dark place. When the seeds are dry, you'll be able to shake them right out of the flower heads.

Pods like chilies and peppers are dried whole in a commercial dryer, in the oven, or by stringing them together and hanging them in a dry, airy place. Store them in jars or by hanging. Grind as needed in a coffee grinder, spice grinder, or mortar and pestle for use in chili powder or paprika.

Garlic cloves and onion pieces can also be dried using a commercial dryer or your oven. Store the dried pieces in a tightly covered glass jar. Grind as needed for garlic powder or onion powder.

Using frozen herbs: Clever chefs are learning that the herbal pantry is not limited to fresh or dried herbs. The freezer provides a hospitable environment for many herbs and spices because its low temperature helps them keep their flavors longer.

What's more, if you need to grind your dried spices ahead of time, freezing will preserve their flavors longer than keeping them at room temperature.

Many frozen herbs can be used as you would fresh—about 2 teaspoons to serve four people. Take the herbs from the freezer and toss them (without defrosting) into soups, stews, and sauces. If you're using frozen herbs in salads or other uncooked foods, drain them first. (Frozen minced herbs will need more draining than sprigs.) Note that flavors can change during freezing, so be sure to taste and, if necessary, adjust before serving.

Tips for freezing herbs: Tough stemmed herbs like basil, tarragon, and sage should have their leaves removed for freezing. Brush off the soil with a stiff paintbrush rather than washing because too much water may dilute flavors. Once the leaves have been brushed and removed, lay them out flat on a cookie sheet and freeze them for several hours. Then place them gently into freezer containers or bags, and they'll be easy to remove individually as needed.

The big question when freezing herbs is whether or not to blanch. Although the color of the herbs will usually stay greener if they're blanched, flavor and aroma will often be sacrificed.

Basil is an exception: It should be blanched, or it will turn black. Most other herbs will freeze well unblanched for up to six months if it is done just after harvesting. After that time, blanched or unblanched, they'll begin to deteriorate.

To blanch, simply place the leaves in a strainer and pour boiling water over them for one second. Then lay them on paper towels and let them cool in the air before freezing. Don't be tempted into cooling the leaves by plunging them into ice water, because it could dilute their flavor.

Delicate herbs like thyme and dill freeze well in sprigs. Simply arrange them in freezer containers or bags and seal. Use whole frozen sprigs or snip them as needed.

Herbs can also be minced by hand or with a food processor and frozen in ice cube trays. When the cubes are frozen, transfer them to plastic bags and use as needed.

Another way to freeze minced herbs is by making herb pastes. Add fresh leaves or sprigs to a food processor and begin to mince. While the motor is running, add oil, a bit at a time, until the mixture has formed a paste. Freeze the paste in ice cube trays or in tablespoon amounts wrapped in plastic.

Making herbed vinegars: Herb-flavored vinegars add magic to any recipe that asks for vinegar. They offer aroma to foods just as rhythm adds excitement to music, without overpowering the harmony of the recipe.

Choose white vinegar, white wine vinegar, red wine vinegar, apple cider vinegar, or rice vinegar, depending on the herbs you're adding. Heat the vinegar but don't boil it; then pour it into a glass jar to which you have added fresh herb sprigs or leaves. Use about three 2-inch sprigs for each cup of vinegar. Garlic, shallots, or chilies can be used, too, by adding one for each cup of vinegar.

Let the vinegar cool, then cover it, and store in a cool, dark place for up to a year. Use the vinegar in salad dressings and marinades and to deglaze pans.

Making flavored oils: Flavored oils can be a dieter's dream. The secret is that you can use less because the oil is more flavorful. For example, on a salad to serve four people, you might make a dressing using 2 tablespoons of oil. But if you use a flavored oil, you can cut the amount in half, and the dressing will be so flavorful, nondieters will be jealous.

Gently heat olive oil, peanut oil, or other vegetable oil until it's warm and fragrant. This will take three to five minutes, depending on how much oil you're heating. Then pour the oil into a glass jar to which you have added fresh herb sprigs, herb leaves, garlic, or chilies. Use about three 2-inch sprigs, one clove of garlic, or one chili for each cup of oil. Let the oil cool, cover, and store it in a cool, dark place for about six months. Use the oil to sauté and in marinades and salad dressings.

Making herb butters: Like flavored oils, herb butters allow calorie counters to use less because there's more flavor. They also jazz up a breakfast table or an appetizer tray with wonderful colors and tastes. Try serving herb butters in tiny ramekins (crocks), shaping them in butter molds, or cutting them with a butter curler.

Continued ➔

Combine about 1 tablespoon of minced fresh herbs with ½ cup softened sweet butter. Wrap the mixture in plastic and store it in the refrigerator for about a month or in the freezer for about three months. Use the butter on warm biscuits or toast, steamed vegetables, poached chicken, or fish. Use it to sauté.

Classic Herb and Spice Combinations

Our tastes are expanding and as they do, the flavors of many countries are finding their way into our kitchens. When we use a pinch of Indian curry powder to spike a sauce or a dash of Spanish saffron to spice a soup, we are enriching ourselves with the classics of other cultures.

Bouquets garnis are the little bundles of aromatic herbs and spices used to flavor soups, stews, and sauces. The idea behind a bouquet garni is to keep the herbs contained so that flavor, but not flecks, will permeate the food. The little bundles can be made up of several fresh herb sprigs tied together with string; fresh or dried herbs tied in a cheesecloth bag; fresh or dried herbs placed in a tea ball; or fresh or dried herbs tucked between two pieces of celery and tied with string. When using a bouquet garni that is tied together with string, make the string long enough that you can tie the loose end to the pot handle. Then when you need to remove the bouquet, it will be easy to find.

Classically, bouquets garnis contain parsley, thyme, and bay with occasional additions of whole peppercorns, whole allspice, whole cloves, celery leaf, tarragon, or marjoram. Be encouraged to expand on the bouquet concept by creating your own removable bundles. For instance, combine cinnamon stick, orange peel, lemon peel, and nutmeg to flavor warm apple cider. Or use lemon peel, whole peppercorns, and garlic together to spice up simmering vegetables.

Bouquets garnis can be made ahead in cheesecloth bags and frozen. Add them to simmering food directly from the freezer.

Fines herbes are a combination of chervil, parsley, thyme, and tarragon, freshly minced and added to omelets, sautés, cheese sauces, and other recipes at the very last minute of cooking. The allure of fines herbes is in the freshness of the herbs and the satisfying flavor they create when combined.

Quatre epices simply means "four spices" and is used in French haute cuisine to flavor roast meats, poultry, hardy vegetables, or desserts. The four spices are a ground combination of any of the following: cloves, mace, nutmeg, ginger, cinnamon, black pepper, or white pepper. Without the peppers, quatre epices become good old American pumpkin pie spice.

Curry powder does not grow on trees. Instead, it is an aromatic combination of many ground spices that can include coriander seed, cumin seed, nutmeg, mace, cardamom seed, turmeric, white mustard seed, black mustard seed, fenugreek seed, chilies, ginger, white peppercorns, black peppercorns, garlic, allspice, cinnamon, cayenne, and fennel seed. Curry powder is famous in East Indian cooking where, depending on the spice combination, it is called garam masala. It is also imported to Southeast Asian cuisines, especially Thai. Note that Thai curries (except for Thai Muslim curry) omit the sweeter spices like cinnamon, ginger, nutmeg, and mace and include lots of fresh basil. Thai curry powders are commonly combined with a liquid and used as pastes.

To enliven its exceptional aroma, curry powder should always be heated before eating.

Chili powder is a combination of ground spices and herbs that always contains dried chilies plus a selection of garlic powder, oregano, allspice, cloves, cumin seed, coriander seed, cayenne, black pepper, turmeric, mustard seed, and paprika. As with all dried spice and herb combinations, chili powder is best when ground as needed and heated before eating. If you must make chili powder ahead, store it in a tightly covered glass jar and keep the jar in a cool, dark place.

Chinese five-spice powder is a dried, ground combination of Szechuan peppercorns, cinnamon, cloves, fennel, and star anise. It's used as a seasoning for pork and chicken and as a condiment. Five-spice powder is most flavorful ground as needed and heated before serving. If you're using five spice powder as a condiment, toast it first in a dry sauté pan. If you must store five spice powder, keep it untoasted in a tightly covered glass jar in a cool, dark place.

Pickling spice often includes dillweed and/or dill seed plus a choice of dried chilies, mustard seed, bay, allspice, white peppercorns, black peppercorns, cinnamon, cloves, coriander seed, turmeric, cardamom, ginger, celery seed, garlic, mace, and nutmeg. Sound confusing? Simply choose your spices according to what you're pickling. For instance, for cucumber pickles, use dillweed, dill seed, mustard seed, celery seed, garlic, and black peppercorns. Now imagine that you're pickling carrots. Think about what flavors enhance them. You could choose cinnamon, nutmeg, bay, and peppercorns.

Salt-Free Blends

Are you one of the millions who monitor salt intake for health reasons? Don't despair! You aren't doomed to a tasteless diet.

The four basic tastes we perceive are sweet, salty, sour, and bitter. Imagine what can happen if one of those tastes, in this case salt, is removed. If you're thinking "bland," you're right. But you can achieve high flavor levels without salt. By raising the flavor levels of sweet, sour, and bitter, you can create wonderful blooms of flavor that will stimulate your taste buds. Here are some salt-free flavor combinations for marinades, sauces, and for sprinkling.

For beef:

- lemon juice, minced fresh rosemary, and freshly ground black pepper
- minced fresh thyme, ground cloves, grated orange peel, and freshly ground black pepper

- garlic, herbed vinegar, and freshly ground black pepper
- mashed green peppercorns, minced onions, and minced fresh marjoram

For poultry:

- minced fresh ginger, freshly grated orange peel, and minced fresh sage
- minced fresh marjoram, minced fresh thyme, and apple cider vinegar
- minced fresh tarragon, minced shallots, and lemon juice
- minced fresh basil, white wine vinegar, and garlic

For fish:

- minced fresh dill, lemon juice, and mustard seed
- minced fresh lovage, celery seed, lemon juice, and freshly ground black pepper
- fennel seed, mustard seed, bay, and grated lemon peel

For green vegetables:

- minced fresh savory, minced fresh chives, and minced onions
- minced fresh dill, bay, and rice vinegar
- minced fresh basil, freshly grated nutmeg, and minced fresh marjoram

For yellow and orange vegetables:

- cinnamon, nutmeg, orange juice, and minced fresh thyme
- minced fresh ginger, cinnamon, apple cider vinegar, and minced fresh lovage or celery leaf
- minced fresh bee balm and minced fresh thyme

For cheese and eggs:

- minced fresh dill, minced fresh chives, minced fresh parsley, and paprika
- freshly grated nutmeg, dry mustard, and freshly ground black pepper
- minced fresh oregano, garlic, and minced fresh thyme

For beans, rice, and other grains:

- chilies, cumin seed, minced fresh oregano, and garlic
- saffron, garlic, and minced fresh parsley
- minced fresh mint, minced fresh parsley, grated lemon peel, and caraway seed

Sweetness Enhancers

Many herbs and spices sweeten the foods around them without adding calories. Use them alone—a pinch of cinnamon to sweeten tomato sauce—or in combination with traditional sweeteners—cardamom adds extra sweetness to cakes and cookies, for example. Experiment with these natural sweeteners:

- angelica stem in salads
- bee balm in beverages
- costmary and mint in sparkling waters
- lemon balm and lemon verbena in frozen desserts
- violet and rose in condiments
- vanilla (just a drop) in savory sauces
- rosemary in fruit salads, fruit compotes, and fruit tarts

Edible Flowers

Many flowers can add color and an outdoorsy, perfumelike flavor to your cooking. They are frequently used as floating garnishes for beverages and soups and to add color to trays and individual plates. But their flair reaches far beyond. For example, edible flowers can be minced and added to cheese spreads, herb butters, or to pancake, crepe, or waffle batter. Use them whole in salads, stuffed, or fried in a light cornmeal or flour batter.

The key word here is *edible*, which is a nice way of saying nontoxic.

Crafts from Herbs

Claire Kowalchik and William H. Hylton

Herbs invite but don't intimidate. Nearby, abundant. Rich in textures, colors, and fragrances. There's a special satisfaction from turning such homey materials into an elegant piece of craftwork.

The pleasure is not all in the result; the process itself soothes and refreshes. There are no acid baths, no deafening machinery with finger-eating blades. Herbs are quiet and fragrant, and the herb crafter's hands smell of rosemary and thyme.

But the greatest charm of herb crafts may perhaps be described as their quirkiness. A finished project shows immediately what's growing by your garage or roadside or what a neighbor happened to plant too much of. Each piece becomes absolutely personal, local, and distinctive, a refuge of the individual spirit in a formularized, mass-produced world.

Living Herb Wreaths

Wreaths make year-round pleasure for Peggy Armstrong, an herb crafter from Ohio. Peggy starts her living wreaths in the spring when she has lots of young plants and is ready to start her other herb plantings; the wreaths become circular herb gardens she happens to hang on the wall. During the summer they thrive hanging against the cedar boards on the outside of her house. When they come inside for a visit, lying on a tray of stones, a hurricane lamp in the center, they make a fragrant centerpiece for a table. One of her favorite wreaths is a treat for the palate as well as the eye, a perfect gift for a good cook:

1. Soak several handfuls of sphagnum (not milled) in water until wet throughout, about 15 minutes. Cut a strip of ½-inch-mesh chicken wire 3 inches wide and 14 to 18 inches long. Bend the long sides of the wire, so they curl up to form a trough. Squeeze enough water out of the sphagnum, so it won't drench the table while you work; then pack it tightly into the trough. (A good dense mass of sphagnum will give the plants a firm base and will hold water well.)
2. Bend the trough sides together until they overlap slightly and you have a long wire sausage stuffed with sphagnum. Fasten the sides together by bending the loose prongs (sticking out where the mesh was cut) to form little hooks that can catch in the mesh hole on the opposite side of the seam.
3. Make five to seven little wells in the sphagnum, evenly spaced about the wreath, by poking through the wire. Plant a young herb in each, anchoring wayward runners with hairpins, if necessary. Peggy uses plants from 3-inch pots whose creeping stems are about 6 inches long. She encourages wreath makers to choose plants boldly in hopes of discovering striking effects. She has certainly not been timid or tradition bound; some of her wreaths include a bright cascade of petunias.
4. Hang the wreath in strong but indirect sunlight. Peggy puts hers on the west side of her house. When the moss starts to dry out, she soaks the whole wreath for 15 minutes in a tub of water with a dash of plant fertilizer. If herb tendrils start growing in odd directions, prune them back or wire them into shape. In about six weeks, you should have a fully covered wreath.

Plants for Living Wreaths

For culinary wreaths:

chives (plant at the bottom center if the wreath is to be hung)

creeping sage

marjoram

oregano

thymes, especially creeping wooly thyme

For fragrant wreaths:

lavender

prostrate rosemary

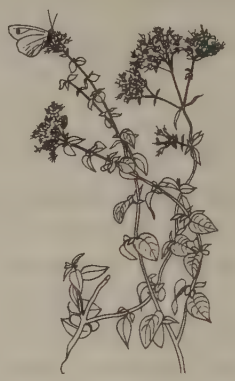
santolina

scented geranium

To add color:

marigold

petunia



Living Christmas Balls

These little globes have some of the same magic as ships in a bottle. Fortunately they're easier to make. They can hang near windows (but out of direct sun) or on Christmas trees, and they make unusual holiday gifts.

1. Find glass Christmas balls 2½ inches in diameter with chimneys at least ½ inch in diameter. Pull off the metal tops and save them. Soak the balls overnight in a half-and-half solution of bleach and water. Then, wearing rubber gloves, swirl each ball in the solution, letting the bleach slosh around inside. Rinse them with plain water. The color should wash off easily. If any trace remains of the color or the cloudy inside coating, rub it off with a paper towel. To reach the inside, use a long-handled cotton swab or a bit of paper towel stuck on the end of a pencil.
2. Mix crumbled charcoal (available wherever aquarium supplies are sold) into a soilless potting mixture (half sphagnum and half perlite, for example). You'll need about 1 teaspoon of charcoal and ¼ cup of potting mixture per ball. Rest the ball in a cup to keep it from rolling around while you work on it. Form paper into a funnel, insert it into the ball's chimney, and pour in the charcoal-soil mix. It should fill a quarter to a third of the ball.
3. Push bits of trailing moss through the opening, and position them with a pencil or needle-nosed tweezers to form a loose carpet over the soil.
4. Take a 1¾-inch-long cutting of partridgeberry, preferably including some berries (the red will make the final ball more festive), and remove the bottom pair of leaves. Using tweezers, poke the cutting through the chimney and into the soil. Make sure at least one node is below ground. Put the point of a long-necked squeeze bottle into the ball and mist the soil.
5. Put the cap and hook back on the ball and if the mood strikes, tie a ribbon around the ball's chimney. Hang it in indirect light and mist the soil when the moss begins to look faded. The ball will make a perfect rooting chamber for the partridgeberry and the moss.

Tussie-Mussies: Bouquets with Meaning

"Making things that are pretty is one thing, but making them meaningful is another," says Lane Furneaux, a master of both arts. From her herb garden in Dallas, she's reviving enthusiasm for tussie-mussies, pretty bouquets of herbs and flowers. What is special about a tussie-mussie is that each plant in it has a meaning.

These little nosegays have been familiar British accessories for centuries, but the Victorians raised them to the level of language, particularly the coy exchanges of flirtation. A young dandy might reassure a distant lady with a tussie-mussie of forget-me-nots (for true love) and rosemary (for remembrance) and perhaps southernwood (for constancy). If she didn't find the bouquet convincing, she might send back yellow roses (for infidelity) and larkspur (for fickleness). He'd best rush for the white violets (innocence) or a lot of rue (repentance). After laying waste to several flower borders, they might get the matter sorted out, or perhaps she would finish the liaison with one scorching handful of fumitory (for hatred).

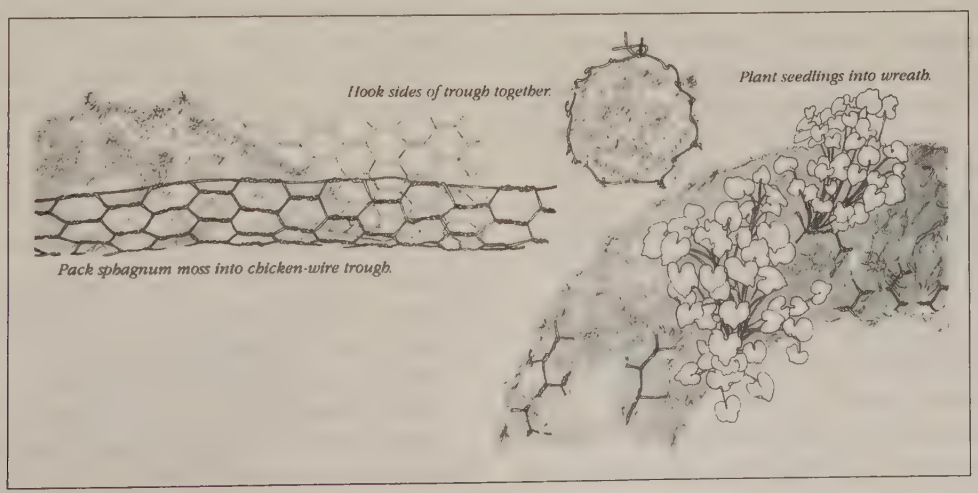
Today's revival of tussie-mussies seems to have sidestepped the lovers' quarrel (an herb patch is unlikely to replace the telephone) and concentrated on creating pretty and meaningful—and fragrant—bouquets for brides, new mothers, departing friends, new neighbors, or anyone in need of a kind word. The little bouquets have even entered politics. As legislation to form the National Herb Garden wobbled through Congress, various legislators received pleas for support in the form of tussie-mussies. The legislation did pass, which might give pause to anyone inclined to dismiss the power of a handful of flowers. To create your own flower power, here is Lane Furneaux's advice.

Selecting the plants: "Tussie-mussies are something you make with what you have," Lane emphasizes. Using only the plants from the backyard or a nearby field makes the bouquets absolutely distinctive and expressive of the maker. She describes seeing a tussie-mussie in *National Geographic* whose maker was not identified. She wrote to ask about the maker, commenting that the style didn't look American to her, and if she had to guess, she would say that it had been made in England, at Claverton in Bath. Several weeks later, she received an astonished phone call from the staff; she had guessed exactly right. She urges newcomers to relax: "Every garden has what it needs for a tussie-mussie."

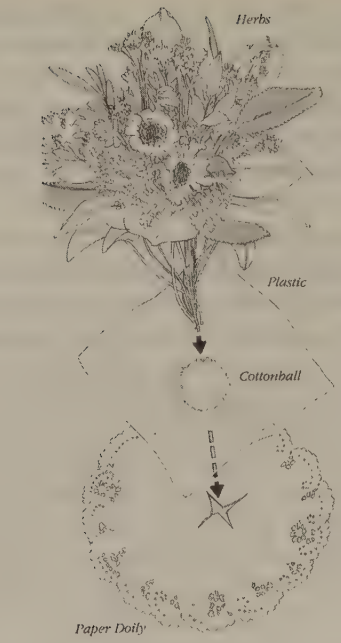
The plant that represents the main message is Lane's starting point. This is the flower that will go into the center. She strolls through her garden searching for plants that express her theme, preferably something colorful. Perhaps opal basil flowers for good wishes, a rose for love, or a pair of roses for an anniversary bouquet. She selects other plants with complementary meanings, and finally she just picks anything that is in particularly good condition or would make a good combination for the flowers. These last plants she looks up on returning indoors, and often she discovers that their sentiments would be perfect for the occasion. She has made tussie-mussies with as few as 2 kinds of plants and as many as 36. (The 36 went into a tussie-mussie for Nancy Reagan to whom Lane had a lot to say.)

Arranging the plants: According to Lane arranging the plants is like writing a letter. It's an activity so intuitive and personal that rules become irrelevant. Here is her approach:

Starting with the plant symbol for the main sentiment, the one that will go at the center, she surrounds it with a little frame of foliage, perhaps some kind of mint for fragrance. Next a ring of something wispy is added for contrast. With a strongly symmetrical center, Lane arranges little bunches of the remaining plants asymmetrically around the outer part. (Some tussie-mussie makers use only one sprig for each sentiment, but bunching the sprigs makes a more dramatic display.) In this outer section, Lane looks for ways to accent the center color. The bouquet is finished with an outer rim of leaves, perhaps from different kinds of scented geraniums. Lane will alternate a triangular leaf with a round one, for example. Or perhaps make two rings of contrasting leaf shapes.



Continued



Assembling the bouquet: Put the sprigs in water, and then wash them, in Lane's words, "just as if they were something to eat." Groom them, cutting off spent blossoms or chewed leaves, until each sprig is perfect. Lane strips the lower leaves, although this is a matter of personal style. At Claverton, for example, tussie-mussie makers retain the leaves, crushing them together when the stems are wrapped. It makes for a bulkier base but more fragrance.

For a bouquet that will be carried, spread out a square of plastic wrap and put a little puff of moist cotton in the center. Then fold up the square so that it engulfs the stems of the bouquet, twisting it around the stems like the flaps of a folded umbrella. Cover it with a spiral of florist's tape.

Tussie-mussies are often set in a paper doily. Cut an X in the middle of the doily, fold down the points, and put the stems through the hole in the doily. Lane secures them with a ¼-inch florist's pin through each point of the X-cut. If the bouquet is eventually going into water, the doily can get pretty soggy. Lane creates a little wax protector for the doily by dipping the points of the X-cut in paraffin before inserting the bouquet stems.

Decorate the assembly with ribbon. Lane uses three colors to spiral up the stem and tie over the pins. She lets long ends trail down.

A tussie-mussie should stay fresh for several hours when wrapped this way. To keep it longer, snip off the base of the plastic container, or better yet, unwrap the stems. Set them in a glass of water. If you have included a large number of plants that dry well, set the tussie-mussie in a glass without water and wait. When the bouquet dries, remove any sprigs that didn't dry gracefully and rewrap the stems.

A final note. Include a message with the tussie-mussie explaining what you intend the plants to symbolize. Even a fellow speaker of the floral language might appreciate clarification on plants that have several meanings. And never give anyone unlabeled basil, which can mean either love or hate.

Woven Herb Baskets

The easiest way to make these unusual craft baskets is to start with plenty of fresh herbs, weave them while they're at their most pliable, and then let them dry. These highly textured baskets with a heathery blending of colors make a dramatic container for any number of displays—pinecones, glass balls, rag dolls, or dried flowers.

The following design comes from the irrepressibly creative herb crafter Peggy Armstrong:

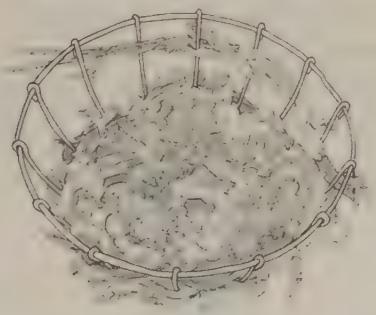
1. Start with a moss basket (the wire frame baskets that florists stuff with sphagnum moss and plant with hanging plants). Garden centers carry several sizes, particularly in the spring. Collect herbs with long stems and, ideally, feathery foliage but with few pronounced branches. Leave flowering stalks on, but break off any part of the stem that's too woody to bend.
2. To weave the first row, select one or two leafy stems. Anchor one end of the bunch by poking it very far down into a crack between two ribs at the base of the basket frame. Weave the herb stem(s) over and under the wire ribs. Press the stem(s) down against the base as firmly as possible. The stem(s) will probably go all the way around the base with a bit left over. Then just use the same stem(s) to start the next row. Weave under the ribs you went over the first time and vice versa.
3. When the first stem(s) have been completely woven in, select another one or two stems. To anchor, lay the stem(s) over the previous row so they overlap about an inch, going under and/or over the same ribs as the previous row. Then continue weaving around the basket. When you reach the beginning again, start the third row, passing the herbs under the ribs you have just gone over and vice versa. That's the basic pattern;

you'll just keep repeating it until you reach the top. The most important part of the process is packing down the layers firmly. Otherwise large holes will appear in the basket as the stems dry and shrink. As you weave higher on the frame, one bunch of stems will not reach all the way around. Don't worry. Just select another bunch, let it overlap, and go on weaving.

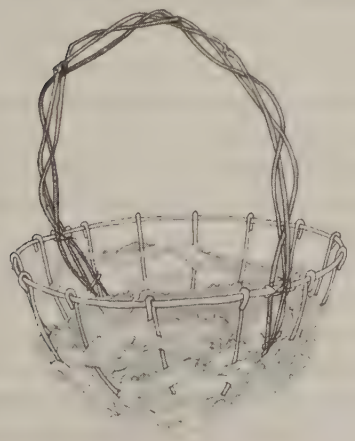
4. After you have woven about an inch of the basket, increase the size of the herb bundle by one stem. Thus you might be weaving with three stems instead of two. About every inch up, increase the size by another stem. (The thicker bunches will give a sturdier, more dramatic basket, but it's impossible to use them near the base. There the ribs are so close together that thick bunches can't bend sharply enough to get around them.) In selecting these thick bunches, don't waste the prettiest stems by burying them in the middle. Put them where they will show on the basket's outside or inside. By composing the stem bunches carefully, you can streak colors from the top to the bottom of the basket, or give the basket's inside a different character from the outside.

5. When you've woven three-quarters of the way up the frame, add a handle. Peggy makes a semicircle of grape vines or plaited herb stems and wires each end against a rib with florist's wire. Continue weaving herb bunches through the ribs, going over or under the handle as if it were just another rib.

Weave herbs into a wire-frame basket.



Add a handle by wiring each end to a rib of the basket.



6. When you come to the top, fasten southernwood around the top edge with florist's wire to hide the metal rim.

7. Prop the basket upside down, perhaps on jars so it can dry.

Drying Herbs and Flowers for Decoration

In drying flowers we play a trick on Mother Nature—and discover the laugh is on us. At first a dried arrangement seems like such a magnificent way to break the rules: When everything turns dry and brown for the winter, we can have tufts of silvery, fuzzy leaves, tiny blue petals, clumps of tawny flowers, hundreds of echoes of summer. But consider the "unnatural" trick: The principal way of drying herbs and flowers is just a matter of warm air, a light breeze, and a couple of days. It's Mother Nature's trick after all.

AIR-DRYING—FOR THE RIGHT FLOWERS

Colonial Williamsburg, a sort of carnival of preservation technology, preserves its herbs and flowers in the simplest way possible. Staff members tie them in bunches, hang them in a dark attic with a dehumidifier, and wait. There are other ways to dry plants, says Libbey Oliver, who supervises Williamsburg's flower arranging, but air-drying produces a look appropriate to the colonial atmosphere. (Silica drying—described later—she considers more Victorian.) Air-drying is certainly the simplest drying technique, but like any other simple task, it can be refined into an art.

Here, step-by-step, is how to do it:

1. **Choose plants that work.** The most common mistake that beginners make, says Libbey, is to try to air-dry the wrong things. The technique just doesn't work on some plants, particularly those with large petals that shed (like tulips or full-blown roses) or those with delicate structures that shrivel (like Queen Anne's lace).

2. **Pick flowers at the right stage.** Some do best when picked half open; they open more as they dry. Others do best

Continued ➔

when left to dry as much as possible on the vine (see the accompanying list, Flowers for Air-drying).

3. **For flowers, strip the leaves.** The less plant material on each stem, the faster the piece will dry. Of course, no stripping is necessary in drying foliage.

4. **Tie 8 or 10 stems in a bundle and hang them upside down.** Libbey uses a rubber band to make a slipknot around the bundle and then hooks the open loop around a clothespin on a clothesline in her drying attic.

   The drying area should be dark and well-ventilated. Air movement is the key. Heat won't be much help if the moisture has no place to go. Williamsburg's drying attic has dark paper over the windows and vents at each end. During the summer flowers dry in an average of 10 days.

5. **As soon as the flowers are dry, pack them in boxes.** Libbey adds a few mothballs. The important rule here is to arrange the flowers so you'll never have to dig through a heap to find the ones you want. Therefore, put only one kind in a box and label each box clearly.

DRYING POWDERS—FOR FINICKY FLOWERS

If hanging flowers in the attic just produces a drift of petals on the floor, try one of the powder methods. The slowest method is to bury the flower in fine sand in an open box. The sand holds the bloom open and the petals in shape while the air dries the flower. Borax, clean sand mixed with borax, plain kitty litter, and numerous other powders will do this. Flowers dry in this mixture in two to five weeks.

One powder—silica gel—actually draws water out of the plant. Finding it may be a challenge. Try drugstores, hobby shops, and florists. Silica gel costs perhaps $6 per pound, but after each batch of flowers, the powder, which looks like a laundry detergent, can be dehydrated in a warm oven and then reused. Flowers dry in this mixture in two to seven days. Afterward they may be particularly sensitive to humidity and may reabsorb moisture and droop if placed in a humid part of the house. The ideal way to display them in such a case is under a Victorian bell jar.

Flowers for Air-Drying

Flowers to pick before fully open:

delphinium (spike should be half open, half in bud)

goldenrod

peony (dry the buds)

pokeberry

safflower (pick when some flowers are still in bud; let top leaves remain)

strawflower

Flowers to pick when fairly open:

celosia (before seeds appear)

chive flowers

marigold (will dry into dark gold pompoms)

salvia

Flowers to leave on stalk until very dry:

globe amaranth

pearly everlasting

tansy

yarrow (yellow is best)

Foliage to pick in prime condition:

artemisia

Pods to let dry on plant:

love-in-a-mist

rue seed heads (pick either green or dried)

Whatever the drying powder, the method of packing is the same:

1. Pick flowers for powder drying when they're not quite fully open. Cut off the stem right under the blossom. Poke a piece of florist's wire into the center of the flower, and pull it through until it forms a wire "stem." Bend one end of the wire into a little nubbin so it won't pull through the stem and out the bottom. (The flowers will be too fragile to wire once they're dried, but the wire is essential if you want to stand the flowers in a vase.)
2. Cover the bottom of a wide, low container with a thin layer of drying powder, and nestle the flowers into the powder, with the wires curling around them. Don't let the blossoms touch. Gently pour in the remaining powder, completely burying the flowers. If the powder is silica gel, seal the container tightly. For other powders, leave the container open.
3. Try to catch the flowers when they're dry enough to hold their color, but not so dry that they fall apart. Flowers with thin petals may dry in two days, while fleshier flowers like snapdragons may take a week. Don't leave flowers in silica gel "an extra day," because they can overdry. Excavate them from the powder very gently because they'll be extremely brittle. If a petal breaks off, reattach it with a spot of white glue.

Dried Herb Wreaths

Pastels. Little pinpricks of color. Airiness, softness.

Dried herbs have opened up thousands of possibilities for wreaths. The herbs may not be evergreen, but they're practically ever ready. Instead of discarding the wreath in January, add a Valentine's Day bow and use it as a centerpiece. Hang a hatchet in it for George's birthday . . . .We are just beginning to glimpse the decorative possibilities of wreaths.

We are also just beginning to glimpse the range of techniques. Here are two approaches from skilled herb workers; you can invent at least a dozen more.

Eileen Weinsteiger's dried herb wreaths: Eileen Weinsteiger takes care of the display herb and vegetable gardens at the Rodale Research Center. Create your own wreath following Eileen's instructions:

1. Select a wreath base of straw or Spanish moss. These are available at garden centers or can be made by bending heavy gauge wire into a circle and lashing a filling material to it with florist's wire.
2. Pick a "background" plant—something that you have tons of and that will go well with all the flowers you intend to use in the wreath. The pale fluff of Silver King artemisia, for example, makes an excellent background. Insert it in the straw, stem by stem, until the whole wreath is covered.
3. Now add the accents, perhaps little bouquets of colorful dried flowers, spaced around the wreath connected by stretches of more neutral flowers. Or perhaps a whole circle of harmonious dried flowers with a few contrasting colors stuck here and there. You might wire in several florist's tubes so you can add fresh flowers, replacing them when they fade.

Peggy Armstrong's dried herb wreaths—any shape: Your imagination and flower supply are your only limitations in making this wreath:

1. Cut a long strip of heavy-gauge wire for the spine of the wreath or garland, and bend a hook into each end.
2. Assemble a bunch of dried flowers, perhaps 3 inches across, representing a balanced arrangement of the foliage and color accents you want in the wreath. Using fine florist's wire, bind the stems to the big wire.

Just keep adding bunches until you've covered the wire. The most important part is keeping the bunches close to each other. Otherwise there will be gaps when the wire is bent. (Peggy prefers to keep the composition simple. She advises people to use no more than three basic colors.)

3. When you have filled the wire or run out of flowers, bend the garland into whatever shape you want. You can have a wreath, a heart, a circle with Mickey Mouse ears, or whatever. Peggy has even wound herb garlands around the poles of umbrellas at a poolside party.

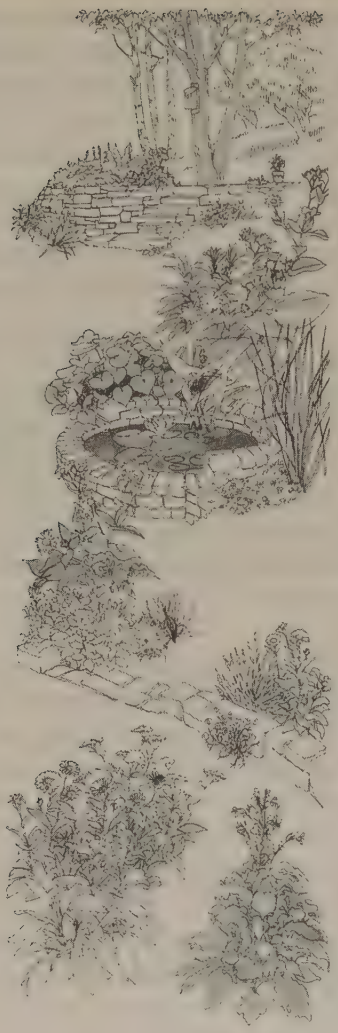
Herb Garden Designs

Claire Kowalchik and William H. Hylton

There are two ways to landscape with herbs: Work them into the overall design as decorative elements, or feature the herbs in special period or theme gardens. If you don't have the room or desire for an herb garden, herbs can still make a valuable contribution to your landscape.

A low hedge of lavender or rosemary can set off a fence or wall or line a path, perfuming the air when anyone walks through. If you're tired of mowing grass, a colorful lawn of creeping thymes, chamomile, and/or pennyroyal requires almost no maintenance.

Continued →



(Remember, though, that an herb lawn won't hold up under heavy traffic—if you want to walk on the lawn, it's best to set down stepping stones.) On a smaller scale, creeping thymes, with their pleasantly pungent fragrance and pink, white, rose, or lilac flowers, can be planted between the bricks or stones of a path, spreading to form a colorful ground cover.

Ground covers for shady sites need not be limited to ivy or pachysandra, either. Plant sweet woodruff, with its starry white flowers, mint-scented pennyroyal, or heavenly sweet violets under your shade trees. If part of your yard is heavily shaded, angelica, lemon balm, sweet cicely, evening primrose, valerian, chervil, goldenseal, lungwort, and the hellebores will add color and texture. Reclaim a swampy site with lovage, marsh mallow, mint, elecampane, queen of the meadow, and bee balm.

Herbs can also be worked into a flower border or vegetable garden. Bright-flowered bee balm; gold, white, or cherry yarrow; garlic chives with its clusters of star-shaped, rose-scented flowers and handsome straplike foliage; variegated sage; daisy-flowered feverfew; blue-green rue; blue-spired aconite; and foxglove with its majestic spikes of flowers in shades of red, pink, yellow, and white are particularly suited to the mixed border. So much variety to choose from makes it easy to design a striking border.

In the vegetable garden, annual and biennial herbs like nasturtiums, basil, parsley, anise, dill, borage, chervil, coriander, calendula, and summer savory add diversity and possibly protection from insects. But to avoid grief at tilling time, confine the perennial culinary herbs, such as sage, thyme, and their like, to a site of their own at one end of the garden, just like those other perennial crops, asparagus, strawberries, rhubarb, and artichokes.

Landscaping

If you use herbs on a larger scale or feature them in a design or garden, good commonsense landscaping rules apply, as they do in any type of garden design. Before you start to design, remember that all gardens involve work. The more formal the design and the larger the scale, the more weeding, clipping, mulching, and watering you'll need to do. Scale down those visions of grandeur until they reach manageable proportions.

When you begin the actual design, bear in mind that it's a lot easier—to say nothing of cheaper—to make mistakes or changes on paper than in the garden. Measure the garden site, then transfer the outline to graph paper, making the layout to scale. Mark down trees, buildings, and other obstructions, and note the direction north. Make sure to leave enough space for comfortable paths, and keep beds narrow enough to work in—4 to 5 feet is about maximum—but wide enough to look effective. Once you have the basic design down, choose the herbs that will bring it to life. The choice can be based on color, height, climatic conditions, or type of plant—for example, those suitable for a colonial or dye garden.

It's wise to keep basic rules in mind when choosing plants. First, always plant groups of a given herb together. Individual plants will get lost, creating a blurred, jumbled effect, while masses of plants will stand out and create a unified design. Second, plant in descending order of height. If your design features a border backed by a wall or fence, plant the tallest herbs in back, the lowest herbs in front. If you're planning an island bed, put the tall plants in the center, the low plants around the edge. Third, keep perspective in mind. If you're planting a knot garden, make sure the garden "floor" contrasts with the knotted "cord," or the pattern will be lost. If your design is meant to be viewed from a distance, use plants that will show up—large ones with bright flowers or silver foliage.

Finally, a word about maintenance. Herb gardens, like any others, look best when the plants are full and lush. This is vital when an herbal hedge or solid block of plants is integral to the design. It's good gardening practice to grow extra plants in a nursery area or corner of the vegetable garden, so you'll always have spares to fill in gaps.

Period Gardens

Period gardens are complex because they are limited to the designs, materials, techniques, and plants of a given historical era. Before embarking on a historical design, read everything you can on the period of your choice, as well as on garden design in that period. An Elizabethan knot garden design is included here as a starting place. But there are other possibilities.

A medieval garden is a delightful refuge. It should be walled, if possible, and include a fountain. Surround the fountain with an herbal lawn studded with flowers—irises, clove pinks, lilies, daisies, primroses, sweet violets, and columbines.

If you have a tree in the garden, you can build a circular seat around it. But the most traditional seating arrangement is a turf seat under an arbor. The turf seat—a medieval inspiration—is an earth-filled rectangular box surfaced with a creeping herb such as one of the prostrate thymes or creeping chamomile. Its walls can be brick, stone, wood, or plaited wicker (wattling).

The vigorous formality of a colonial garden may seem far removed from the enclosed tranquility of a medieval bower, but the symmetry of a successful colonial garden is soothing. To make a colonial herb garden, lay out raised, board-sided beds along a central walk. The two sides of the garden should be identical. The walk should lead to something—a sundial, bench, or view. If possible, fence the garden, or hedge it with santolina, lavender, rosemary, or southernwood.

Colonists often planted herbs randomly with vegetables and flowers. An all-herb garden should be planted informally within the rigid framework of the design. Colonial herbs include burnet, comfrey, dill, basil, clary sage, lemon balm, parsley, nasturtiums, rue, madder, woad, mint, fennel, saffron, coriander, chamomile, angelica, caraway, borage, chervil, tarragon, licorice, lovage, tansy, sweet cicely, catmint, and calendula.

One thing to bear in mind when attempting a historical re-creation is to limit yourself to materials available in the period you're reproducing. For example, wood, wattling, stone, gravel, brick, and clay were the usual building materials used in the colonial days. Local materials were usually used in garden construction, down to sheep-shank edgings for beds. This sort of attention to detail, combined with a sound design and diligent maintenance, will guarantee you a successful herb garden.

Theme Gardens

A theme garden is one in which the plants are unified by a common feature, such as flower color or function. Five such garden designs are included here to inspire you—a medicinal garden, dye garden, fragrance garden, everlasting garden of ornamental plants for drying, and kitchen garden. Other possibilities include a white garden, with silver-foliaged and white-flowering herbs; a seasonal garden, with herbs that bloom in your favorite season; an herb tea garden; and a "meaningful garden," with message herbs so popular in Victorian bouquets (such as rosemary for remembrance or borage for courage).

Theme gardens can also have literary significance. There are Shakespearean gardens all over this country, featuring plants mentioned by the bard. Biblical gardens, featuring wormwood, rue, hyssop, aloe, anise, mint, dill, coriander, mustard, saffron, cumin, and roses—all herbs mentioned in the Bible—are popular. Some include plants associated with the Virgin, such as rosemary, costmary, lady's mantle, and lady's bedstraw.

Plants for a Knot Garden

Because a knot garden is basically an indulgence, you can play with it in whatever way you wish. You could emphasize the formal geometry of this pattern by using a single plant throughout. You could use all one plant for the central accents and keep three kinds in the borders. Or you could reduce the borders to two kinds—one for the square and a second for the "loops" of the knot. You can play with the background, too. A single mulching material—cocoa bean hulls—is used here to accent the greens, blues, and grays of the herbs. You could use different stone chips to make a mosaic—white marble chips in some sections, black in others, and gray-blue crushed granite in others. Or you could use brilliantly colored fish, tank gravels to create patterns that would have thrilled the Elizabethans.

Another option is to simplify and reduce the size of the knot garden. A striking knot can be made in a 9- or 10-foot square. The thing to bear in mind is that knot gardens were originally intended to be viewed from above—as when one looked from one's terrace or castle window. The narrower and lower the herb borders, the closer you'll have to get to the knot for it to be effective—and the more maintenance it will require to keep those herbs in bounds.

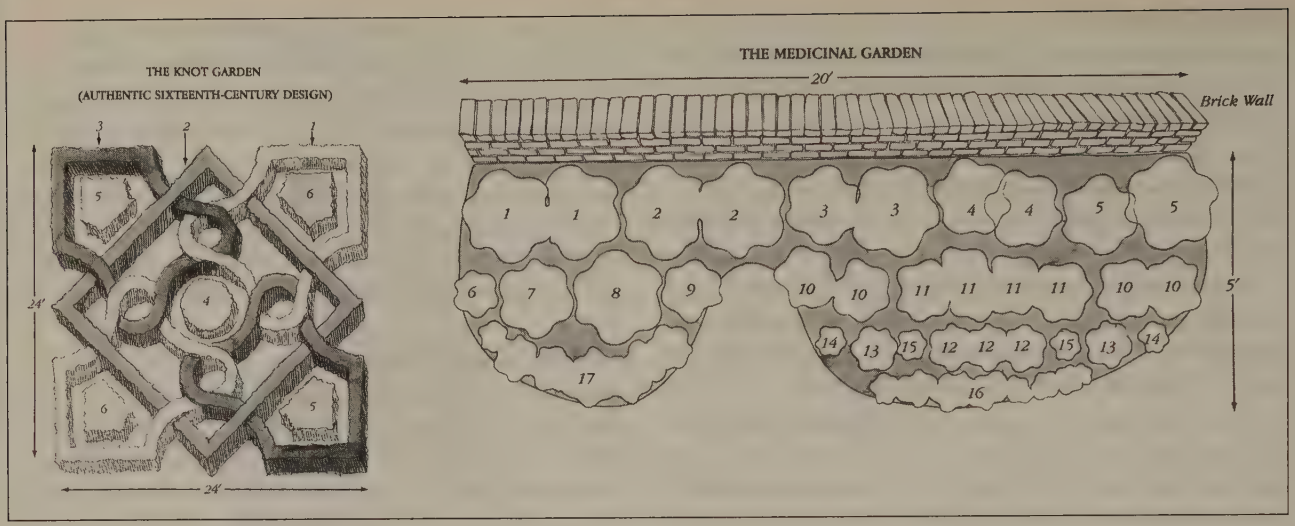
The plants:

1. GREEN SANTOLINA (*Santolina virens*): A perennial, to 2 feet tall, with rich green, aromatic leaves and yellow flowers in early summer. Plan on one plant per foot of border. Keep plants clipped back to about a foot—a hard clipping in early spring, followed by a light trim every two weeks from late May through July should keep them looking neat.

2. MUNSTEAD LAVENDER (*Lavandula angustifolia* spp. *angustifolia* 'Munstead'): A compact perennial, only 1 foot tall, with aromatic gray foliage and bright lavender flower spikes in summer. Plan on one plant per foot of border. Trim only if needed to keep plants in bounds during the growing season, but prune back hard in early spring for bushy growth. Will probably need winter protection, such as a covering of evergreen boughs.

3. GERMANDER (*Teucrium Chamaedrys*): A perennial, to 2 feet tall and wide, with dark green foliage and pink flowers in midsummer. Plan on one plant per foot of border. Clip it as you would green santolina.

Continued →



4. LAVENDER COTTON (*Santolina chamaecyparissus*): A perennial, to 32 inches tall and wide, with finely cut, aromatic silver-gray foliage and yellow cottonball blooms in summer. Plant as a specimen. Prune back hard in spring to keep it from becoming woody, then shear lightly for a mounded effect.

5. HYSSOP (*Hyssopus officinalis*): A perennial, to 3 feet tall, with aromatic green foliage and white, blue, or pink flowers in summer. Plant on 2-foot centers. Shear to desired shape.

6. BLUE BEAUTY RUE (*Ruta graveolens* 'Blue Beauty'): A perennial, to 2 feet tall, with blue-green, ferny, aromatic foliage and yellow flowers in summer. Plant on 2-foot centers. Shear to desired shape.

Other plants that make handsome knot borders include dwarf and edging box, American germander, 'Hidcote' lavender, mother-of-thyme, lemon and golden lemon thyme, gray Roman and fringed wormwood, sage, winter savory, sweet marjoram, rosemary, and southernwood. Creeping thymes can be used in place of sand, stone, or mulch to fill in the design between the borders. The entire knot garden can be framed in brick or stone (preferably set no wider or higher than the borders).

Knot gardens are not low-maintenance propositions. Besides requiring constant pruning, winter protection, and standard good cultural practices, they need a supply of backup plants. Nothing looks quite as dreadful as a ratty knot garden border, with brown or empty patches where herbs didn't make it through the winter. Keep a nursery of "squares" of all the plants you use in the knot in an out-of-sight border so you'll always have replacements ready.

Plants for the Medicinal Garden

These days, plants for the medicinal garden are chiefly for show. While you may make a cup of comfrey or chamomile tea, or try your hand at horehound drops, or gather a bouquet of aconite, foxglove, and feverfew, many medicinal plants are poisonous and are best admired for their historical significance and left in the garden. The half kidney shape of this garden subtly reinforces its medical theme.

The plants:

1. VALERIAN (*Valeriana officinalis*): A perennial, 3½ to 5 feet tell, with pinnate leaves and clusters of fragrant white, pink, or lavender flowers from June through September. Plant on 2-foot centers. Oil from the roots has been used as a sedative and painkiller.

2. GENTIAN (*Gentiana lutea*): A perennial, to 6 feet tall, with deep-veined leaves and showy yellow flower clusters in late summer. Plant on 2-foot centers. The root has been used as a digestive aid, vermicide, and antiseptic wound treatment.

3. MULLEIN (*Verbascum thapsus*): A biennial, 3 to 6 feet tall in flower, with a basal rosette of large, woolly leaves and a large spike of lemon yellow flowers from June through September. Plant on 2-foot centers. The flowers have been used to treat coughs, congestion, and tuberculosis and were smoked to soothe pulmonary diseases.

4. ELECAMPANE (*Inula helenium*): A perennial, to 6 feet tall and 3 feet wide, with large basal leaves, smaller upper leaves, and yellow daisylike flowers in summer. Plant on 2-foot centers. The rhizome has been used to treat respiratory diseases.

5. AMERICAN HELLEBORE (*Veratrum viride*): A perennial, to 7 feet tall, with broad, ribbed leaves and a spike of yellow-green flowers in midsummer. Plant on 2-foot centers. The rhizome has been used as a sedative, emetic, and to treat hypertension. All plants are poisonous.

6. COMFREY (*Symphytum officinalis*): A perennial, 3 to 5 feet tall, with large, hairy basal leaves and white, rose, purple, or yellowish bell-shaped flowers from May through frost. Plant on 1½-foot centers. The root has been used to reduce inflammation and to heal broken bones.

7. LOBELIA (*Lobelia inflata*): An annual, to 3 feet tall, with toothed leaves and blue or white flowers in July and August.

Plant on 1½-foot centers. The entire plant has been used to treat asthma, as a nerve stimulant, and as a tobacco substitute.

8. FEVERFEW (*Chrysanthemum parthenium*): A perennial, to 3 feet tall and wide, with aromatic, fingered foliage and creamy white, buttonlike flowers midsummer through fall. Plant on 1½-foot centers. The flowers have been used as a sedative and tonic.

9. BETONY (*Stachys officinalis*): A perennial, 2½ feet tall in flower, with a basal rosette of round-lobed leaves and spikes of white, pink, or reddish purple flowers from mid- to late summer. Plant on 1½-foot centers. The leaves have been used as a poultice, emetic, tonic, nervine, and sedative.

10. ACONITE (*Aconitum napellus*): A perennial, to 3 feet tall, with deep green, finely divided leaves and dark blue hooded flowers in large spikes in July and August. Plant on 1½-foot centers. The rhizomes have been used as a sedative, painkiller, and to treat rheumatism. All parts are poisonous.

11. FOXGLOVE (*Digitalis purpurea*): A biennial, 3 to 4 feet tall, with large, wrinkled leaves and huge spikes of white, cream-yellow, pink, rose, lavender, or purple bell-shaped flowers, often with speckled throats, which bloom in June and July. Plant on 1½-foot centers. The leaves have been used as a heart stimulant and to treat dropsy. All parts are poisonous.

12. ARNICA (*Arnica montana*): A perennial, to 2 feet tall in flower, with a basal rosette of long leaves and yellow daisylike flowers in midsummer. Plant on 1-foot centers. The flowers have been used as a compress for bruises, wounds, and inflammation. All parts are poisonous.

13. ECHINACEA (*Echinacea angustifolia*): A perennial, to 2 feet tall, with long, narrow leaves and lavender daisylike petals curving back from tall orange cones; plants flower in mid- to late summer. Plant on 1-foot centers. The roots are still used by some herbalists as an anti-infective.

14. MANDRAKE (*Mandragora officinarum*): A perennial, to 1 foot tall, with a basal rosette of wrinkled leaves and greenish yellow bell-shaped flowers borne singly in late spring. Plant on 1-foot centers. The root has been used as a painkiller and sedative. All parts are poisonous.

15. WHITE-WOOLY HOREHOUND (*Marrubium incanum*): A perennial, 2 to 3 feet tall and 15 inches wide, with hairy leaves and whorls of white flowers in summer. Plant on 1-foot centers. The leaves and flowers have been used for coughs and colds.

16. ROMAN CHAMOMILE (*Chamaemelum nobile*): A perennial, 1 foot tall in flower; with 2- to 4-inch-tall mats of feathery, fruit-scented foliage and white daisylike flowers from June through August. Plant on 6-inch centers. The flowers have been used as a sedative and hair rinse.

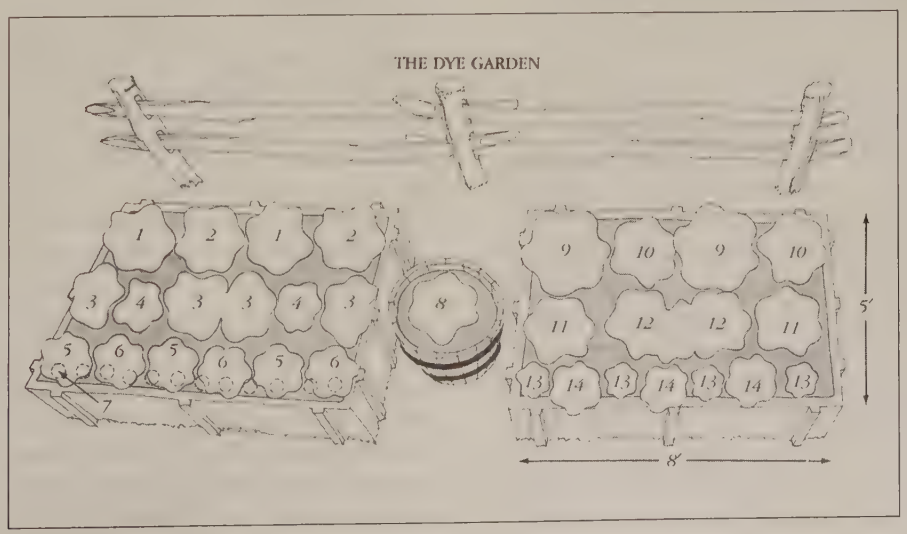
17. AUTUMN CROCUS (*Colchicum autumnale*): A perennial bulb, to 1 foot tall and 3 to 4 inches wide; straplike leaves wither in summer and are followed in September by rose-purple flowers. Plant on 6-inch centers. The seeds and corms have been used to treat gout and rheumatism. All parts are poisonous.

Plants for the Dye Garden

Even though dye plants formed an integral part of most dooryard gardens before the invention of chemical dyes, they were never "domesticated" like their more civilized culinary and fragrant cousins. As a result, they retain a rustic, meadow-plant feel and should be given a simple setting. Ours features half-barrel and rectangular, board-sided raised beds, with the framing staked in place. A split-rail fence or dry-stone wall makes the perfect backdrop to the dye garden. Some dye plants are familiar annual flowers—marigolds, zinnias, and calliopsis—and these have been incorporated in the design for added color until the herbs fill in. In subsequent years, they can be removed or space left for them, as desired.

The plants:

1. QUEEN OF THE MEADOW (*Filipendula ulmaria*): A perennial, to 4 feet tall, with large, bright green, lobed leaves,



Continued ➔

and fragrant, white, feathery plumes in June and July. Plant on 2-foot centers. The roots yield a black dye; the leaves and stems, harvested when the plants are just coming into bloom, yield a greenish yellow with alum used as a mordant.

2. WELD (*Reseda luteola*): A biennial, 5 feet tall in flower, with a basal rosette of long, slender, lance-shaped leaves and long, slender, yellow flower spikes in summer. Plant on 2-foot centers. The whole plant in full flower yields a lemon yellow dye with alum used as a mordant; a golden yellow with chrome; and an orange with alum and tin.

3. GOLDEN MARGUERITE (*Anthemis tinctoria*): A perennial, one of the most ornamental herbs, 2 feet tall and white, with aromatic, feathery green leaves and masses of 2-inch, yellow daisylike blooms from June through August. Plant on 15-inch centers. The flowers yield a yellow dye with alum used as a mordant; a gold dye with chrome.

4. MARIGOLD (*Tagetes* spp.): An annual, with deep green, aromatic, feathery foliage and single to double flowers in yellow; gold, orange, burgundy, and rust; also bicolors and white. Choose bushy plants in the 2-foot range, and plant on 15-inch centers. They'll bloom summer through frost. The fresh or dried flowers yield yellow, gold, orange, brown, gray, or green without a mordant; yellow with alum used as a mordant.

5. LADY'S BEDSTRAW (*Galium verum*): A perennial, to 3 feet tall, but often creeping, with whorls of narrow, pale green leaves and small yellow flowers in panicles in July and August. Plant on 15-inch centers. The roots yield light red with alum used as a mordant; purplish red with chrome. The flowering tops yield yellow with alum or chrome used as a mordant.

6. MADDER (*Rubia tinctorum*): A perennial, to 4 feet tall, but often prostrate, with whorls of leaves and greenish yellow, inconspicuous flowers in early summer. Plant on 15-inch centers. The 3-year-old roots, dried, yield a rose-red or lacquer red with alum used as a mordant; garnet red, orange, or rust with chrome; bright red or Turkey red (on cotton) with tin. The fine reds of old quilts and oriental rugs were created with madder dyes.

7. SAFFRON (*Crocus sativus*): A perennial bulb, saffron is indicated by dotted lines, as it sends up 1½-foot-long, thin, straplike leaves in spring, which die in midsummer. In September saffron bears 2-inch, lilac cup-shaped flowers with bright orange stigmata. Plant on 4- to 6-inch centers. The stigmata yield yellow with alum used as a mordant; gold with chrome. Because the tiny stigmata must be hand-harvested in great quantity to yield dye, saffron dyes have always been the property of the elite and the stuff of legend.

8. SOAPWORT (*Saponaria officinalis*): A perennial, domesticated varieties 1 to 2 feet tall, with 2- to 3-inch, lance-shaped leaves and large pink blooms in panicles from July through September. Plant on 15-inch centers. Soapwort is not a dye plant but is included in the dye garden for authenticity's sake, as the roots were used to make a soapy lather in which the yarn was washed before dyeing.

9. SAFFLOWER (*Carthamus tinctorius*): A perennial, to 3 feet tall, bushy plants with toothed, bright green lance-shaped leaves and striking scarlet-orange-yellow thistle-shaped flowers in summer. Plant on 2-foot centers. The fresh or dried flowers yield yellow with alum used as a mordant; red in an alkaline solution. It is often called poor man's saffron.

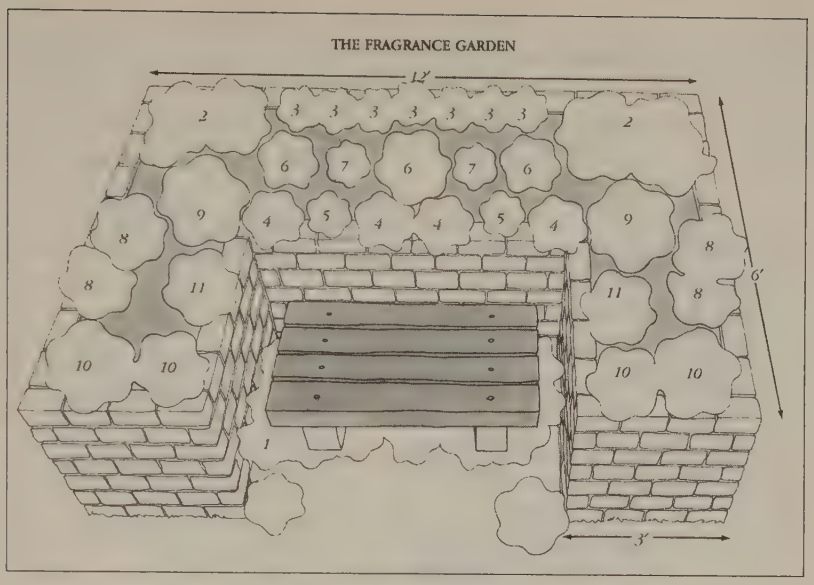
10. GOLDENROD (*Solidago* 'Goldenmosa'): A perennial, to 3 feet tall, with erect stems, slender, spear-shaped leaves, and handsome golden yellow plumes in August and September. Plant on 2-foot centers. The flowers and leaves yield yellow, gold, tan, yellow-green, avocado, olive green, bronze, brown, and khaki; yellow with alum used as a mordant; old gold with chrome. This much-maligned plant is not the source of hayfever (the real villain is ragweed). It is one of the most attractive dye plants. While 'Goldenmosa' is suggested, try any of the tall, domesticated varieties.

11. WOAD (*Isatis tinctoria*): A biennial, 3 feet tall in flower, with a basal rosette of 1-foot-long blue-green leaves and large panicles of cloudlike yellow blooms in May and June, followed by clusters of black berries that can be used in dried arrangements. Plant on 2-foot centers. The young leaves, picked fresh and fermented, yield blue; mature leaves treated in the same manner yield blue-black; weak solutions yield green. The only temperate-climate source of blue dye (tropical indigo also yields blue), woad is indisputably the most stunning dye plant in flower. It's also one of the most historic, having been used by the Picts of England as a styptic for battle wounds, causing them to appear in what was taken by the disconcerted Roman invaders as blue war paint.

12. ST.-JOHN'S-WORT (*Hypericum peiforaturn*): A perennial, to 2 feet tall, with yellow flowers in July and August. Plant on 2-foot centers. The flowering tops yield yellow and gold; the whole plant yields yellow-green with alum used as a mordant; gold with chrome; bronze with blue vitriol; yellow-green with iron and tin.

13. ZINNIA (*Zinnia elegans*): An annual, 6 to 36 inches tall, with opposite, spear-shaped leaves and double blooms to 7 inches across, with quilled, pointed petals, in white, pink, orange, red, green, purple, yellow, and multiples, from summer through frost. Plant one of the Biz-foot cultivars on I-foot centers; remember to choose a color or colors compatible with the reds, yellows, and golds of the rest of the bed. The flowers yield yellow with alum used as a mordant; bronze with chrome; bright gold with tin; gray-green with iron; khaki with blue vitriol.

14. CALLIOPSIS (*Coreopsis tinetoria*): An annual, 8 to 48 inches tall, with spindly, needlelike leaves and yellow, purple-red, or bicolor daisylike blooms summer through frost. Plant on 1-foot centers. The fresh flowers yield bright yellow with alum used as a mordant; bright orange-yellow with tin; rusty orange with chrome. If picked after frost, the flowers yield dull gold with alum; brown with chrome and iron; dull rust with chrome and tin.



Plants for the Fragrance Garden

The bloom season in the fragrance garden extends from the first sweet violets in April until the nasturtiums are killed by late fall frosts. Summer is a blaze of color—blue, white, lavender, apricot, and gold. But fragrant flowers are only half the story. The delightfully scented foliage of rosemary, scented geranium, lemon balm, lavender, catmint, the thymes, and nasturtiums can be enjoyed all season. The design brings the plants to nose level for a heady feeling when you're sitting on the bench; the violets form a soft carpet underfoot.

The plants:

1. SWEET VIOLET (*Viola odorata*): A perennial, 6 inches tall in spreading clumps; blooms in April and May with the classic violet fragrance. Violets prefer partial shade so they are planted under the bench and in the shelter of the brick wall. Plant all violet 'Royal Robe,' or mix them with 'Red Giant,' 'White Czar,' and 'Rosina.'

2. SNOW WHITE BEE BALM (*Monarda didyma* 'Snow White'): A perennial, 3 feet tall; blooms in July and August. Give these plants a 2-foot circle; they will spread. Both the tubular flower clusters and the leaves are fragrantly lemony.

3. HIDCOTE LAVENDER (*Lavandula angustifolia* subsp. *angustifolia* 'Hidcote'): A perennial, 1½ feet tall and up to 1½ feet wide; blooms in June and July with deep violet-blue flower spikes. Both the flowers and the silver-gray foliage are highly fragrant, with the intensely pungent lavender scent. Place 1 foot apart to form a solid "hedge."

4. MOTHER-OF-THYME (*Thymus serpyllum*): A perennial, creeping ground cover 3 inches tall; bears tiny lavender flowers in June and July. The small, shiny evergreen leaves are fragrant, with the pungent, salty smell of thyme. Plant 1 foot apart; plants will trail over the brick edging for a cascade effect.

5. LEMON THYME (*Thymus x citriodorus*): A perennial, clumping herb 4 inches tall; bears small rosy blooms in June and July. The light green leaves have a wonderful lemon fragrance. Give them 1-foot circles.

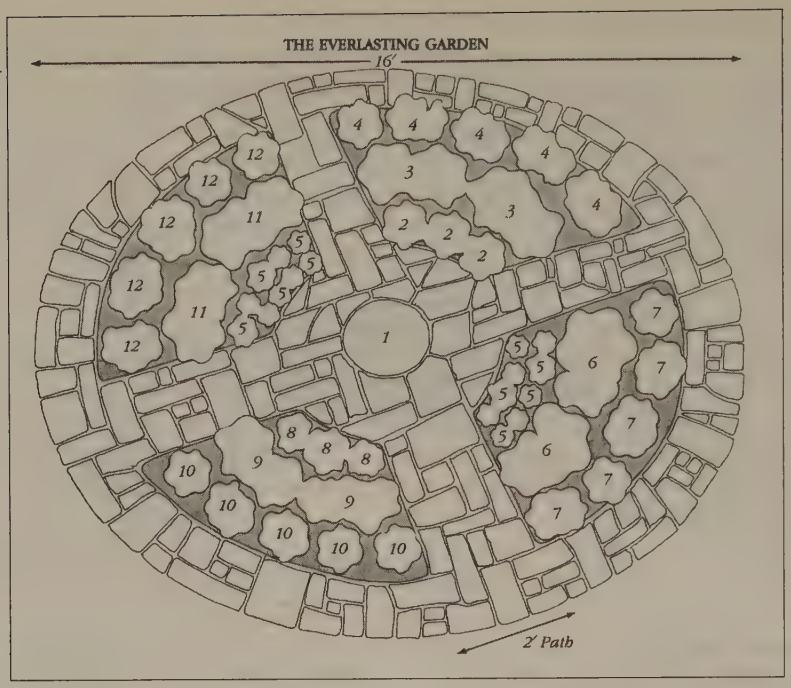
6. SCENTED GERANIUM (*Pelargonium* spp.): A perennial in Zones 9 and 10, where it may reach 3 feet tall. In colder areas cuttings or pot plants must be set out after all danger of frost has passed; plants will probably reach 1½-foot height and width in one growing season. Pink through lavender flowers are borne in summer. The soft, fuzzy green or bicolored foliage is highly fragrant. There are hundreds of scented geraniums; plant all of one kind or mix them. Favorites include lemon-scented geranium (*P. crispum*), with tiny crinkled leaves; *P. crispum* 'Variegatum,' with creamy white leaf margins; rose-scented geranium (*P. graveolens*), with large, fingered leaves; and peppermint-scented geranium (*P. tomentosum*), with downy, maplelike leaves. Give plants 1½-foot circles.

7. LEMON BALM (*Melissa officinalis*): A perennial; may reach 2-foot height and width in flower; blooms July through September. Flower heads should be cut back to keep plants from wantonly self-sowing. Scalloped green foliage is strongly lemon scented. Plant in 1½-foot circles.

8. BLUE WONDER CATMINT (*Nepeta mussini* 'Blue Wonder'): A bushy perennial, 12 to 15 inches tall, which covers itself with 6-inch blue flower spikes in spring and early summer. Fuzzy foliage smells minty. Shear plants back after flowering for rebloom in fall. Give plants 1-foot circles.

9. GARLIC CHIVES (*Allium tuberosum*): A perennial, to 2 feet tall; spreads in clumps. Straplike blue-green foliage contrasts nicely with the more leafy herbs. Plants cover themselves with rose-scented clusters of starry white flowers in late summer. Cut the bloom stalks before the seeds ripen, or you'll have a forest on your hands in subsequent seasons. Plant garlic chives on 1½-foot centers.

Continued →



10. NASTURTIUMS (*Tropaeolum majus*): An annual; 1 foot tall by 2 feet wide; will cascade over the brick edging. Sea green leaves are succulent and shaped like inverted umbrellas. Both leaves and flowers, which are borne summer through frost in saturated shades of red, apricot, orange, and gold, are strongly scented, with a unique, nose-pinching, pepper-perfumy smell. Sow after all danger of frost has passed. Plant on 1½-foot centers.

11. WHITE-FLOWERED ROSEMARY (*Rosmarinus officinalis* '*Albiflorus*'): A perennial in Zones 8 through 10; otherwise, sink pots in the bed or plant out and pot again in fall. Can reach hedge proportions, but won't north of Zone 8, where it is unlikely to reach 2-foot height. There are several good white-flowered varieties, blooming in early summer. The main attraction, however, is the graceful branches of deep green needles with their delightfully pungent, piny scent.

Plants for the Everlasting Garden

This garden is everlasting in two senses: first, it is composed of perennials; and second, all of the plants may be dried for everlasting arrangements. To dry the flowers or foliage for bouquets or wreaths, cut the stems on a dry day after the dew has evaporated. Because flowers will continue to mature as they dry, cut them before they are fully open. Unless the foliage is ornamental when dried, strip off the leaves; otherwise, you face increased drying times and the danger of mildew. Tie the stems in loose bunches (but make the ties tight—stems will shrink as they dry). Hang the bunches upside down in a dark, warm, well-ventilated room (such as an attic or pantry) for a couple of weeks. Flowers with woody stems can be placed upright in a glass.

Many other plants can be chosen to add color and texture to an everlasting garden. Most of these are considered ornamental flowers rather than herbs. They include the green flowers and foliage of ambrosia; the white, pink, mauve, rose, and purple flowers of statice; the reds, yellows, oranges, and purple-blacks of strawflowers; the silvery foliage of 'Silver King' artemisia; the white flowers of pearly everlasting; the aromatic, gray-green foliage of eucalyptus; and the handsome mauve and green pods of love-in-a-mist. Other herbs that are handsome dried include camphor-scented artemisia, bee balm, dill, elecampane, sage, and hops.

The plants:

1. LAMBROOK SILVER WORMWOOD (*Artemisia absinthium* 'Lambrook Silver'): A perennial, to 3 feet tall, with finely dissected, metallic silvery foliage, which emerges green in spring, and stalks of tiny, yellow, fluffy flowers in midsummer. The foliage is used in arrangements.

2. HIDCOTE LAVENDER (*Lavandula angustifolia* subsp. *angustifolia* 'Hidcote'): A perennial, 1½ feet tall and up to 1½ feet wide; blooms in June and July with deep violet-blue flower spikes. Plant on 1-foot centers. Both the flowers and the silver-gray foliage are highly fragrant and can be dried for arrangements.

3. GOLDENROD (*Solidago* 'Golden Baby' or *S.* 'Goldenmosa'): A perennial, 'Golden Baby' grows 2 feet tall, while 'Goldenmosa' can reach 3 feet; both have erect stems, slender, spear-shaped leaves, and handsome golden yellow plumes borne profusely in August and September. Plant on 2-foot centers. The flowers are used in arrangements; pick them early or they'll turn to loose fluff.

4. YARROW (*Achillea millefolium*): A perennial, 2 feet tall, with aromatic, feathery foliage and flat clusters of creamy white flowers from June through September. Plant on 1½-foot centers. The flowers are used in arrangements.

5. SWEET MARJORAM (*Origanum majorana*): A perennial, 1 foot tall and 4 to 6 inches wide, with small, rounded leaves and showy, deep purple flower heads. Often acts like an annual in temperate areas. Plant on 6-inch centers. The flowers are used in arrangements.

6. TANSY (*Tanacetum vulgare*): A perennial, 3 feet tall, with feathery foliage and yellow button-like flowers from July through September. Plant on 2-foot centers. The pungent foliage is used in arrangements.

7. CORONATION GOLD YARROW (*Achillea jilipendulina* 'Coronation Gold'): A perennial, to 2 feet tall with fernlike foliage and flat clusters of golden yellow flowers in summer. Plant on 1½-foot centers. The aromatic flowers are used in arrangements.

8. MUNSTEAD LAVENDER (*Lavandula angustifolia* subsp. *angustifolia* 'Munstead'): A perennial, 1 foot tall, with aromatic, gray foliage and bright lavender flower spikes in summer. Plant on 1-foot centers. Both flowers and foliage can be used in arrangements.

9. FEVERFEW (*Chrysanthemum parthenium*): A perennial, to 3 feet tall and wide, with aromatic, fingered foliage and ivory buttonlike flowers midsummer through fall. Plant on 1½-foot centers. The flowers are used in arrangements.

10. CERISE QUEEN YARROW (*Achillea millefolium* 'Cerise Queen'): A perennial, to 2 feet tall, with aromatic, feathery foliage and flat clusters of bright cherry red flowers from June through September. Plant on 1½-foot centers. The flowers are used in arrangements.

11. BLUE BEAUTY RUE (*Ruta graveolens* 'Blue Beauty'): A perennial, 2 feet tall, with aromatic, blue-green, ferny foliage and yellow flowers in summer. Plant on 2-foot centers. The aromatic seed heads, which can be picked in the green or brown stage, are used in arrangements.

12. MOONSHINE YARROW (*Achillea jilipendulina* 'Moonshine'): A perennial, to 2 feet tall and 1½ feet wide, with fernlike foliage and flat clusters of cream-yellow flowers in summer. Plant on 1½-foot centers. The flowers are used in arrangements.

Plants for the Kitchen Garden

This kitchen garden is designed to be ornamental, but it is composed—with the exception of borage—of the most common culinary herbs. The borders of the central path are undulations of purple, green, and pink (if you let the 'Dark Opal' basil flower). Plants in the outer borders are on 1½-foot centers so each can be shown to best advantage. A mulch of bark chips or cocoa hulls will accent form and foliage color, as well as keep dirt off the bricks. Mints are invasive. Control them by sinking metal edging strips, preferably a foot deep, around their planting area, or by planting them in sunken bottomless buckets. In either case, leave an inch or so of rim or edging above the ground to control prowling stems. The focal point of the garden is the borage, with its fuzzy foliage and lovely star-shaped blue, pink, or lavender flowers.

The plants:

1. DARK OPAL BASIL (*Ocimum basilicum* 'Dark Opal'): An annual, to 15 inches tall, with dark purple leaves and pink flowers in July and August. For heaviest production of the spicy, fragrant leaves, clip off the flower heads; leave them for the most ornamental effect. Plant on 1-foot centers.

2. PURPLE SAGE (*Salvia officinalis* 'Purpurascens'): A perennial, 12 to 30 inches tall, powder green older leaves, new leaves powder purple, with purple flowers in June. The foliage has a hearty, sausage-like smell; let it grow in subsequent years to fill the borders, or keep it cut back to leave space for the 'Dark Opal' basil. Plant on 1-foot centers.

3. CURLY PARSLEY (*Petroselinum crispum*): A biennial, treated as an annual. Bushy 1-foot-tall plants with dark green, moss-curled leaves. Remove after the foliage dies back at the end of the first season—the following year, the plants' energies will be directed toward producing 3-foot stalks of yellow-green umbels in summer, rather than the flavorful, vitamin-rich leaves. Plant on 1½-foot centers.

4. CHIVES (*Allium schoenoprasum*): A perennial, forming spreading clumps 1 to 1½ feet tall of tubular, deep green leaves, with striking balls of pink to pale lilac flowers in June. Plants do tend to spread, but are easily controlled by division. Plant on 1½-foot centers.

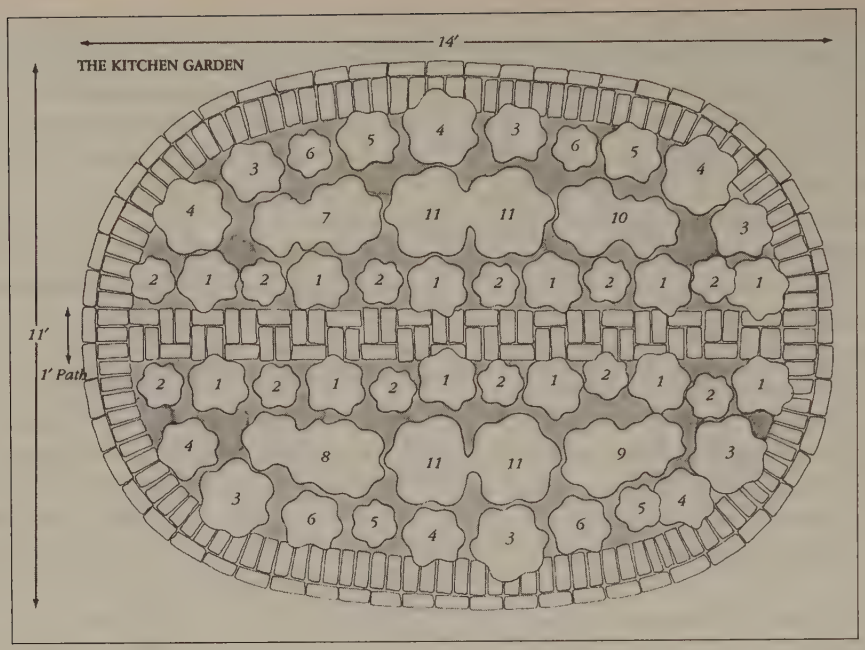
5. COMMON THYME (*Thymus vulgaris*): A perennial, shrubby plant, to 14 inches tall, with small, deep green leaves and tiny mauve flowers in June and July. The name may be common, but the fragrance and fine, salty, pungent flavor are unbeatable. Plant on 1½-foot centers.

6. SPICY GLOBE BASIL (*Ocimum basilicum* 'Spicy Globe'): An annual, rounded mound of tightly packed, pungent, light green foliage to 1 foot tall. Bears light green flower heads in July and August. The most visually appealing basil; you want to pet it. A similar variety is Burpee's 'Green Globe.' Plant on 1½-foot centers.

7. BERGAMOT MINT (*Mentha x piperita* var. *citrata*): A perennial, 2 to 3 feet tall, with long, deep green, purple-tinged leaves, purple flowers in midsummer, and a strong citrus scent. Confine the roots. Harvest or shear back to the desired height. Shear before flowering-mint is invasive enough without encouraging seeding. Plant on 2-foot centers.

8. APPLE MINT (*Mentha suaveolens*): A perennial, to 4 feet tall, with rounded, gray-green, hairy leaves, lavender flowers in midsummer, and a rich fruity scent. Confine the roots. Harvest or shear back to the desired height. Shear before flowering. Plant on 2-foot centers.

Continued →



9. SPEARMINT (*Mentha spicata*): A perennial, to 2½ feet tall, with spear-shaped, bright green leaves, pink, white, or lilac flowers, and the inimitable spearmint scent. Confine the roots. Shear before flowering. Plant on 2-foot centers.

10. PEPPERMINT (*Mentha x piperita*): A perennial, to 3 feet tall, with long, dark green, purple-tinged leaves and purple stems, lilac-pink flowers in midsummer, and the strong, incomparable peppermint fragrance. Confine the roots. Harvest or shear back to the desired height. Shear before flowering. Plant on 2-foot centers.

11. BORAGE (*Barago officinalis*): An annual, 2½ to 3 feet tall, with strong, hairy, large green leaves and star-shaped, drooping, predominantly blue flowers (though they may also be pink and lavender) in midsummer. Flowers and leaves are edible; both are used in salads and fruit salads, while the flowers are refreshing in drinks. The flavor is reminiscent of cucumber. Plant on 1½-foot centers.

Your Seasonal Herb-Care Calendar

Now that you know the basics of growing herbs organically, you'll need to know when to start seeds indoors, direct-sow seeds outdoors, mulch, and prune to give your herb plants conditions in which they can thrive. This calendar gives you, at a glance, what you'll need to do each month.

Also, keep in mind that because of climatic conditions, planting herbs in Florida isn't the same as planting them in Maine. Before you even start planning for herbs, you need to find out what hardiness zone you live in.

January

Although the weather outside may be snowy and cold, you can warm up with thoughts of your garden to come.

- Spend some time paging through gardening magazines and herb books to collect ideas for the upcoming season. Or check out the Web site www.organicgardening.com.
- Read about all the different ways you can use herbs (in cooking, as medicines, and in cosmetics and crafts).
- Inventory your garden supplies to make sure you have the essentials, such as a trowel, a cultivator, and plant markers.

February

With spring around the corner, now is the time to start getting your garden plans together.

- Finalize which herbs you want to plant, and then decide where to grow them—in pots on your patio, on a kitchen windowsill, or in your vegetable garden or flowerbeds.
- Keep in mind that most perennial herbs like well-drained soil, so cluster water lovers (such as basil and parsley) together.
- Buy seeds for fast-growing annual herbs (like borage) to sow directly.

March

Now you can start to get your hands dirty!

- Remove protective winter mulch as you begin to see new growth on your perennial herbs.
- If you're planning on starting annual herbs from seed, now is the time to plant those seeds in flats.

- This month is also a good time to select and prepare a site for a new herb garden. An ideal place would be an area close to your house that gets at least 6 hours of full sunlight each day.

April
Plant new perennial herb plants. Trim woody herbs like lavender as they begin to show new growth. Start basil seedlings indoors for an earlier harvest.

May
You'll have plenty to do this month in your herb garden.

- Plant annual herbs outdoors after your last frost date.
- Direct sow seeds for fast growers like dill and cilantro. To extend your harvest, sow seeds successively every 2 weeks.
- You can also plant tender perennial herbs, such as scented geraniums and rosemary, outside, either in the ground or in pots.
- Dig up and divide large clumps of perennial herbs as necessary.
- Mulch between plants with compost, shredded bark, or another organic material.

June
Continue to sow fast-growing annual herbs such as borage every 2 weeks. Harvest fresh herbs to add flavor to summertime dishes. Pull out weeds that crop up between your herbs.

July
During these lazy, hazy dog days of summer, you should:

- Water as necessary.
- Hang sages and lavender in a dry, dark place for later use in herbal wreaths.
- Make lots of pesto with your basil, cutting off flowerstalks as you harvest.
- Sit in the shade and enjoy a refreshing glass of mint iced tea (or a mint julep) made with mint you picked from your own plants.

August
Use your bounty of herbs to make flavored vinegars and oils. Sow seed for a later harvest of dill and cilantro. Continue to harvest, freezing or drying what you can't use now for use in winter.

September
Dig up and pot tender herbs such as scented geraniums and rosemary. Let them adjust outdoors in their pots before bringing them in. Or take cuttings to root for next year's garden if you don't have space for whole plants.

October
Fall signals the time to begin winding down. This month:

- Clean up the garden after Jack Frost has made his appearance.
- Pull out spent annual herbs and cut back any perennial herbs that need it.
- Organize notes you took from the gardening season and compile them in a binder, along with a map of where each herb grew.

November
Before the ground freezes, add a protective winter mulch of shredded leaves to perennial herbs. Enjoy the season's bounty by using your dried herbs for seasonings in recipes, creating potpourris, and making wreaths.

December
Use evergreen boughs as additional winter protection by laying them over your perennial plants. Give friends and family gifts of potpourris, scented sachets, wreaths, and herbal vinegars that you made with herbs from your garden.

Herb Garden Glossary

Air-dry. To preserve herbs for later use by hanging branches by their stems in a dark, airy place, or by drying them on racks through which air can circulate.

Annual. A plant that germinates, flowers, sets seed, and dies within 1 year.

Beneficial insects. Insects that have a positive effect on garden plants by preying on pest insects or by pollinating plants.

Biennial. A plant that takes 2 years to complete its life cycle.

Bouquet garni. Culinary herbs such as bay leaf, thyme, and parsley, tied in a small bunch and added to soups, stew, or sauces. The herbs are removed before serving.

Companion planting. Combinations of plants that work well together to repel pests, attract beneficial insects, or make efficient use of garden beds.

Compost. Decomposed or partially decomposed organic matter (such as kitchen scraps, leaves, grass clippings, and dead plants) that is dark in color and crumbly in texture. Used as an amendment, compost increases the water-holding capacity of the soil and is an excellent nutrient source for microorganisms, which later release nutrients to your plants.

Compost tea. A fertilizer made by soaking a cloth bag full of compost in a watering can or barrel for several days.

Culinary herbs. Herbs used in cooking.

Continued →

Cutting. A 3- to 5-inch clipping of healthy green growth that is cut from the parent plant and placed in potting mix to root.

Direct seeding. Planting seeds outside directly into the garden.

Division. A way to propagate perennial herb plants by dividing established plants at the roots to form several new plants.

Dormancy. A resting phase for plants that enables them to survive conditions of cold, drought, or other stress, during which they may have no leaves or flowers.

Essential oils. Highly concentrated aromatic oils of plants that are used in cosmetic preparations.

Fish emulsion. An organic liquid fertilizer, made from fish solubles, that contains 4 to 5 percent nitrogen. It is used most often for foliar fertilization (where fertilizer is applied to and absorbed through the plant's leaves).

Full sun. Plants that thrive in full sun need a minimum of 6 hours of direct sun each day. Most herbs prefer a sunny location.

Hardening off. Gradually exposing tender seedlings to the outdoors in a protected area for a week prior to transplanting them into the garden.

Hardiness. Plants are able to tolerate varying levels of cold temperatures and still survive. Plant hardiness zones help gardeners determine which perennials will survive the winter in a specific area.

Herbaceous. A perennial plant that dies back to the ground at the end of each growing season.

Herbicide. A substance used to kill unwanted plants. Some types are selective (they kill only a certain type of plant); others are nonselective and will kill any plants they come into contact with.

Herb standard. A perennial or tender perennial herb plant that is trained to be a single stem with branches only at the top.

Insecticidal soap. A specially formulated solution of fatty acids that kills insect pests such as aphids, mites, and whiteflies.

Layering. Propagating a perennial plant by taking a stem, bending it to the ground, and burying it in the soil. New roots will form underground.

Mulch. Any material, organic or inorganic, used to cover the ground in order to preserve moisture and prevent the growth of weeds.

Organic. Materials that are derived directly from plants or animals. Organic gardening uses plant and animal by-products to maintain soil and plant health and doesn't rely on synthetically made fertilizers, herbicides, or pesticides.

Perennial. Herbs are considered perennial if they last for 2 or more years.

Pesticide. A substance, synthetic or natural, that is used to kill insects, animals, fungi, or bacteria.

Potpourri. A scented mixture of dried herbs and flowers, spices, and essential oils.

Poultice. A soothing herbal paste made by mixing dried herbs with a small amount of hot water. Poultices are put directly on the skin and held in place with a warm cloth.

Rootbound. A condition that results from a plant outgrowing its container, so that the roots are densely crowded and often coiled around the inside of the pot.

Sachet. A fragrance bag made with a combination of dried herb leaves and (frequently) rose petals, crumbled or ground.

Seedling. A young plant grown from seed. Commonly, plants grown from seed are termed seedlings until they are first transplanted.

Self-sow. Herbs such as German chamomile, cilantro, and dill that will reseed themselves if left to go to seed.

Tender perennial. A perennial plant that is treated as an annual because it is being grown outside of its hardiness zone.

Umbels. Flowers, such as Queen Anne's lace, that all have stalks that are the same length and that emerge from the same place on the stem and form a flat-topped cluster.

Volunteers. Plants that grow spontaneously in the garden from a previous year's seeds.

LAWNS

Lawn Care Basics

Jeff Cox

The goal of most homeowners is to have a lush, green lawn that's free of weeds and, at the same time, easy to maintain. In addition, most of us also want to keep the environment cleaner by cutting down on the use of gasoline-powered lawn mowers, and keep our lawns and our families healthy by avoiding the use of lawn chemicals. An ideal way to cut down on lawn maintenance is to turn some of that green grass into a richly textured bed of easy-care groundcovers.

Whether you're looking for ways to make your lawn healthier, seeking solutions to lawn problems, or looking for alternatives to lawns, this chapter will provide you with a wealth of lawn care and groundcover tips and techniques.

Healthy green turf makes everything near it look better. A carpet of green grass also makes a great place to play or relax, while preventing soil erosion and enhancing the value of your home. A good lawn is the result of conscientious gardening practices, whether you're starting a new lawn with a carefully selected cultivar or rejuvenating an existing one.

Build a strong lawn by using grass species adapted to your climate. Encourage healthy growth naturally by letting light grass clippings remain where they fall and by applying compost or other organic material. Relying on high-nitrogen chemical fertilizers can lead to problem-prone, shallow-rooted turf that needs mowing more often. These are some of the most widely grown lawn grasses:

- Bermuda grass (*Cynodon dactylon*), a fine-textured, drought-resistant grass popular in warmer climates. Becomes buff brown in the winter. Numerous runners create a wear-resistant turf. Open-pollinated strains are extremely aggressive; modern hybrids are much easier to keep from invading flower beds.

Continued →

- Buffalo grass (*Buchloe dactyloides*), a creeping, warm-season grass. Tolerates drought and will grow in alkaline soil. Good wear tolerance. Brown in midsummer and fall.
- Centipede grass (*Eremochloa ophiuroides*), a coarser-leaved, warm-season, creeping grass with good drought tolerance. Plant in areas that receive little wear.
- Fine fescues (*Festuca* spp.), dark green, fine-textured, creeping, cool-season grasses with good shade tolerance, often mixed with Kentucky bluegrass.
- Kentucky bluegrass (*Poa pratensis*), a lush, dark green turf grass with narrow blades that requires substantial sunshine. Favored cool-season lawn grass. May become dormant during summer droughts or during winter freezes. Creeping stolons knit a tough turf.
- Turf-type tall fescue (*Festuca arundinacea*), a coarse, medium green grass good for sun or shade, increasingly popular in the central United States. Updated cultivars remain green most of the year. Drought-resistant. Grows in low clumps and doesn't creep, so is often mixed with other grasses.
- Zoysia grass (*Zoysia* spp.), a medium green, creeping, fine-textured grass for full sun. Green in warm weather, tan in winter.

Fertilizing Your Lawn

You don't need to know every grass plant in your yard by name to grow a healthy lawn. The most important thing to note is the time of year when the grass begins to grow rapidly. This is the ideal time to apply a good organic fertilizer. In the North where cool-season grasses have a growth spurt in spring and another in fall, plan to fertilize twice. For warm-season grasses, fertilize in late spring, just as your lawn greens up, and again a few weeks later.

Choose a finely pulverized, weed-free organic fertilizer, such as processed manure or sifted compost, and spread evenly over the lawn just before rain is expected. Mow the grass about a week after you fertilize. Let the nitrogen-rich clippings remain on the lawn.

Maintaining Your Lawn

Lawn maintenance involves more than just proper watering techniques. You also must mow, dethatch, and aerate your lawn regularly to keep it at its best.

Mowing. Sharpen your mower blade at the beginning of each season to make sure the grass blades are cut, rather than torn, when you mow. Remove only one-third of the grass's top-growth. The exact height for mowing depends on the species of grass. Cut low-growing grasses, such as Bermuda grass and zoysia grass, no shorter than 1 inch. Cut taller grasses, such as bluegrass and tall fescue, no shorter than 2 inches. Mow high during summer droughts. To cut very tall grass, set your mower blade at its highest setting. In the course of the next two mowings, lower the blade until you are cutting at the usual height.

If you mow regularly, let your grass clippings lie where they fall. They will eventually rot and add organic matter to the soil beneath. But don't let large clumps of clippings sit on your lawn—they block sunlight and promote disease. Gather them up and use as mulch in other parts of your yard.

Dethatching. All lawns have thatch, a layer of clippings and stems that gradually decomposes and feeds the roots. There's no need to remove it if the layer is no thicker than about ¼ inch. Thatch problems often start with overuse of synthetic chemical fertilizers, which make grass grow fast and lush. As clippings build up into a thick layer of thatch, grass plants are unable to get enough air for healthy growth. Use a thatch rake to break up thatch in a small lawn; rent a vertical mower to dethatch a larger area.

Aerating. Since lawns often bear heavy foot traffic, the soil below them becomes compacted over time. Grass roots have trouble growing down and out and instead concentrate their growth at the surface. Prevent or fix compacted lawns by aerating every two or three years. Aerating a lawn consists of poking tiny holes through the turf into the soil below. Use a step-on core cultivator for small areas; rent a power aerator machine for larger lawns. Mow the lawn and spread a thin layer of organic fertilizer. Aerate in one direction; repeat crosswise. Water the lawn deeply.

Repairing Lawns

Ruts left by heavy vehicles or scars created when shrubs or trees are removed call for prompt spot repairs. If damage occurs in winter, prepare the soil and cover it with a mulch until spring.

Loosen the soil in the damaged site, setting aside any grass plants that seem healthy. Keep them damp and shaded as you work. Add a ½-inch layer of compost or peat moss to condition the soil, along with enough good topsoil to raise the level of the damaged area 1 inch above the soil level of the surrounding turf. Lightly walk over the spot, and fill in any holes or low places. Reseed or replant, matching the primary species in your yard. Water regularly for a month.

Planting a New Lawn

All lawn grasses require at least 4 inches of good topsoil in which to stretch their roots. If your new yard has been scraped down to the subsoil, you will have to spread new topsoil. Site preparation is the same whether you plan to begin with seed or sod: Cultivate new or existing topsoil thoroughly, adding a 1-inch layer of peat moss, compost, or other organic matter. Rake out all weeds and roots, cultivate again, and rake smooth. Use a roller to evenly compact the site and make it level.

The Way to Water

Proper watering techniques will ensure a healthy, lush lawn and will enable you to sustain your lawn's growth even during times of drought. Just follow these steps:

- Water your lawn with occasional deep waterings to encourage grass roots to penetrate deeply into the soil to draw the soil's water and dissolved nutrients.
- Avoid frequent shallow waterings. This only leads to shallow grass rooting.
- During a drought, allow the grass to go dormant by not watering. This allows your grass to "prepare" its natural defenses against a drought.
- Mow high or don't mow at all during a drought. Dried grass foliage helps insulate the crowns so they'll retain more moisture.
- Water sparingly after the grass goes dormant. Provide ½ inch of water every two weeks. This will keep some roots and buds alive but won't bring the grass out of its dormant state.

Be picky when shopping for grass seed. Improved cultivars of the best lawn grasses cost more than their open-pollinated cousins, but they offer superior performance. Choose named cultivars that have been specially bred for drought tolerance, insect and disease resistance, adaptability to shade, or other traits. Use a mechanical seeder for even distribution. Roll after seeding. Keep constantly moist for two weeks. Start mowing three weeks after seeding.

Sod is the fastest way to an attractive lawn, though the cost is higher than seed. It's ideal for spot repairs, especially in high-traffic areas or on slopes. Plant cool-season species in early spring or from late summer to early fall; plant warm-season grasses in late spring to early summer. Use only fresh, green strips. Keep them shaded and damp until planted. Work crosswise along slopes. Roll or walk on the strips after planting to push the roots into the soil. After planting, water newly laid sod every two or three days for three weeks.

Planting Options

Whether you're starting a new lawn or repairing one you've already got, you have several grass-planting options:

Spreading seed: If you're seeding a lawn area, use a spreader to distribute seed evenly. A broadcast-type spreader throws the seeds in a wide swath, so it does the job faster than a drop-type spreader will. When working near flower beds or other nonlawn plantings, the drop type is preferable because it won't cast the seed into your flower beds. Make two passes when seeding an area. On your second pass, walk at a 90-degree angle to the first pass.

Planting grass plugs: Plugs can restore a damaged lawn area. Begin by raking the area to level it and remove debris. Water thoroughly the night before you plan to plant. Use a plugger, auger, or spade to make 3-inch-diameter planting holes in a checkerboard pattern. For good establishment, place 1 teaspoon of blended organic fertilizer in each hole before planting. Plant a plug in each hole. The spacing you use will determine how long it takes for the grass to fill in and form continuous cover. Water again after planting and regularly for the first few weeks. Fertilize your new lawn six to eight weeks after planting.

Laying sod: When laying sod, fit the strips as close together as possible. Be sure to stagger the seams between strips so that they do not line up from row to row. Use a sharp knife to cut sod to fit around walks, edgings, or other obstacles. Rolling sod after laying it improves contact between the roots and the underlying soil and gets the sod off to a good start. On a slope, always lay the rows of sod across the slope, not up and down.

Do any sod patching on the inside. Pieces along the periphery should be whole. If you're patching here and there as part of a renovation (perhaps to cover where a tree has come down or to resod a patch lost to weeds), you should use whole blocks of sod, even if the spot in need is smaller than that. The smaller the piece, the harder it is to keep alive, so cut out a spot big enough to lay in an entire block of sod.

Making spot repairs: Where weeds or lawn pests have caused damaged patches, a partial lawn renovation will usually solve the problem. Clean out weeds and dead grasses with a shovel and rake, till the soil, and amend it with an organic fertilizer. The cultivated patch of soil will compact and settle over time, so rake it into a flat-topped mound slightly higher than the surrounding turf. Plan on planting seed or sod that matches the rest of your lawn, unless you've decided on shade- or drought-tolerant lawn grass for a particularly troublesome area. After sowing or sodding, be sure to firm the soil to ensure good soil contact. Water repaired spots as necessary until the new grass shows strong new growth.

Coping with Problems

A healthy lawn is naturally more resistant to weed, insect, or disease problems. A tight cover of vigorous grass will outcompete weeds. Loose, well-drained soil helps prevent disease problems. Proper fertilization goes a long way toward preventing lawn problems since it encourages growth of strong, healthy turf. Most updated turfgrass cultivars offer genetically improved resistance to diseases and some insects. If you have lawn areas that are chronically problematic, consider replanting them with an improved cultivar or trying an alternative to lawn grass.

Low-Maintenance Lawns

For the best lawn in the least time, follow these tips:

- Limit the amount of lawn in your landscape.
- Keep lawn in large, continuous swaths. Join trees and shrubs with a bed of mulch or groundcovers instead of mowing around and between. Don't plant lawn in hard-to-mow corners.
- Replace aggressive old strains of grass with an improved cultivar or mixture.
- Use lawn edgings and mulch to separate grass from flower beds and trees.
- Accept clovers in your lawn as beneficial nitrogen-fixers, not weeds.
- Where conditions are too steep, too shady, or otherwise unsuitable for a good lawn, choose alternatives such as ornamental grasses or groundcovers.
- During droughts, water modestly once a week. Provide sufficient water to keep your grass alive, but not enough to coax it out of heat-induced dormancy.

There are a few simple steps to take if your lawn develops weed or pest problems. Use a small, sharp knife to slice off any established weeds about 1 inch below the soil surface. If more than half of the plants in your lawn are weeds, it is best to completely renovate the lawn by replanting.

Subterranean insect laevae, such as white grubs, occasionally cause serious damage when they feed on grass roots. Apply milky disease spores for long-term control of these pests. Biological insecticides that utilize parasitic nematodes control numerous insects likely to feed beneath your lawn.

Selecting Lawn Grasses

Barbara W. Ellis

One of the best ways to enhance the overall beauty of your yard is to cultivate a healthy lawn. Whether your lawn is large or small, the first step toward creating a lush green carpet is to choose a lawn grass—or, better yet, a grass mixture—that fits your climate. There are many lawn grasses available today, varying in heat and drought tolerance, active growing season, shade tolerance, and general cultural conditions under which

Lawn Grass Pest Patrol

When your lawn starts to show yellow or brown patches, you can be sure that lawn pests are living in your green carpet. Here's a look at the four most common lawn pests and what you can do to combat them.

Sod webworms: Webworms sever grass blades and cause irregular dead patches in the lawn. Hot, dry conditions and thatch buildup encourage the pests.

Control webworms by saturating infested areas with a soap drench (2 tablespoons liquid dish soap to 1 gallon water) to drive the larvae to the surface. Rake the pests into a pile and dump them into a bucket of soapy water. Apply BTK (*Bacillus thuringiensis* var. *kurstaki*) or drench the soil with parasitic nematodes when pests are in their larval stage (usually about 2 weeks after moths appear). Spray severely infested areas with pyrethrin if all other attempts at control fail.

White grubs: These curved, fat, whitish larvae of Japanese beetles and other beetle species chew on grass roots, leaving sections of lawn that appear burned. Lift out damaged turf.

A check for white grubs. Use a blunt-ended spade to cut through three sides of a square-foot flap of lawn. Gently pry up the roots, and roll the flap back to look underneath. Count the grubs in the ground, and then tamp the turf back down. Ten or more grubs per square foot is a serious infestation. Give the flap a little extra water for a week or two to be sure it reroots.

Walk the turf in spiked sandals (available through mail-order catalogs) that will pierce and kill the grubs. For a large lawn, apply milky disease spores according to package directions; this treatment will eliminate Japanese beetle grubs over a few seasons. Or apply predatory nematodes. Water the soil well before and after application to improve results.

Billbugs: Billbug larvae are white grubs with yellow-brown heads that feed on grass stems, causing shoots to turn brown and die. In warm weather the grubs tunnel into the soil and feed on roots and rhizomes. Billbugs are brown or nearly black ¼- to ½-inch weevils. Control grubs by aerating the lawn, watering deeply, removing thatch, and adding organic matter. Reseed or overseed with resistant cultivars.

Chinch bugs: Chinch bugs and their larvae are common lawn pests virtually everywhere except the Northwest and Plains states. The bugs and the larvae are about 1½ inches long. The bugs have a distinctive inverted-V pattern on their wings.

If your lawn shows ragged yellow or brown patches, you may have a chinch bug problem. Treating problem areas with insecticidal soap is generally effective.

A check for chinch bugs. Cut both ends from an empty coffee can and push the can halfway into the lawn. Pour soapy water into the can and wait 10 to 15 minutes. Then count the number of chinch bugs and/or larvae that float to the top. If you see more than 12, you need to take steps to control the pest.

they grow best. For this reason, experts recommend different grass species for different parts of the country. Whether you're planning to sow seed or plant sod, keep in mind that a mixture of grasses rather than a single species or cultivar is best. (Both seed and sod are generally available as mixtures.) That way, you can take advantage of the best characteristics of several grasses when planting a new lawn or renovating an old one. By choosing a mixture of grasses that are adapted to your climate, soil, and site, you'll be well on your way to a healthy green carpet.

Cool, Warm, or In Between

Grass experts recognize two major groups of lawn grasses—cool season and warm season. Cool-season grasses, which grow best in the northern half of the country, include Kentucky bluegrass, perennial ryegrass, and fine fescues. The fine fescues are further divided into red or creeping fescues, Chewings fescues, and hard fescues. Cool-season grasses typically make their strongest growth in spring and fall but may remain green all winter. They tend to become brown and dormant in midsummer.

Warm-season grasses, which are suitable for the desert Southwest and Sun Belt, include low-maintenance centipedegrass, luxurious-looking zoysiagrass, shade-tolerant St. Augustinegrass, and the incredibly tough, improved cultivars of bermudagrass. These grasses are much more heat-tolerant than cool-season grasses. They are dormant in winter and do not begin to green up until early summer. All tolerate drought better than cool-season grasses.

Gardeners in the transition zone between North and South—as well as in the West and Great Plains—can use a mixture of both cool- and warm-season grasses, commonly called transition-zone grasses. In fact, in the transitional zone, the combination of grass species found in seed or sod mixtures can become quite complex. In the East, the most important grass in the mix is often improved tall fescue, often called "turf type" tall fescue, along with small amounts of other grasses such as bluegrass and annual ryegrass. Improved tall fescues do not creep, so the other grasses in the mix help knit an otherwise tufted lawn into a smooth turf. Buffalograss and blue gramagrass, both warm-season grasses native to this country, are good choices in the western part of the transitional zone, especially in lawns that are not watered. Crested wheatgrass is probably the best choice for lawns that will not be irrigated.

The overwhelming favorite among cool-season grasses is Kentucky bluegrass, a lush, sod-forming turfgrass now available in dozens of named cultivars. The best bluegrass lawns include a blend of four or five updated cultivars that have been selected for such characteristics as color, drought tolerance, disease resistance, and ability to stand up to heavy wear. As the individual grass plants intertwine, the lawn benefits from the collective talents of the different cultivars in the mix.

Choosing the Best Grasses

When choosing any lawn grass, always avoid "common" strains in favor of the newest improved named cultivars. For example, plain Kentucky bluegrass, Kentucky-31 tall fescue, and common bermudagrass are acceptable for roadsides and meadows, but in home lawns they grow too vigorously and become invasive. Named cultivars of lawngrasses often show superior disease resistance, cold hardiness, or shade tolerance. Although many cultivars are available as seed or sod, some of the newest ones—especially of bermudagrass and centipedegrass—are only available as sod, plugs, or sprigs.

Lawn Grasses That Resist Pests

Some grasses, such as zoysiagrass and bermudagrass, are bothered by very few insect pests. But aphids, armyworms, pillbugs, and cutworms can seriously damage succulent stems and stolons of cool-season grasses. In the last decade, scientists have found that some lawn grass cultivars, including 'Repell' perennial ryegrass and 'Rebel' tall fescue, host a type of fungi that protect them from any insect predators. Where insect populations are high, introduction of these pest-resistant cultivars can greatly enhance the health of the lawn.

In Florida and Texas, the southern chinch bug frequently injures lawns. The old St. Augustinegrass cultivar 'Bitter Blue' is extremely susceptible to this pest. Two St. Augustinegrass cultivars, 'Floratam' and 'Floralawn,' show good resistance to this pest.

The following lawn grass cultivars earn high ratings for pest resistance, beauty, and adaptability.

- Kentucky bluegrass: 'America,' 'Midnight,' 'Baron,' 'Glade,' 'Challenger'
- Perennial ryegrass: 'Manhattan II,' 'Repell,' 'Gator,' 'Citation II,' 'Palmer'
- Fine fescue: 'Pennlawn,' 'Ruby,' 'Dawson,' 'Atlanta,' 'Jamestown'
- Hard fescue: 'Reliant,' 'Spartan,' 'Scaldis'
- Turf-type tall fescue: 'Hawk,' 'Rebel,' 'Mustang,' 'Houndog,' 'Apache'
- Bermudagrass: 'Tifway II,' 'Tiflawn,' 'Midiron,' 'Vamont,' 'Texturf 10'
- St. Augustinegrass: 'Floratam,' 'Floralawn,' 'Floratin'

Continued

In most mixes, the shortcomings of bluegrass—its inability to grow in heavy shade and the tendency of some cultivars to germinate slowly—are dealt with by adding other cool season grasses to the lawn's plant population. Fine fescues are the top choices for lawns growing in shady spots in cool climates. Fast-germinating perennial ryegrass is added to bluegrass mixtures to provide short-term cover while the bluegrass becomes established.

Several older lawn grasses have lost popularity in recent years. Bentgrasses have earned a well-deserved reputation as high-maintenance, disease-prone grasses. In the South, many homeowners have become disenchanted with zoysiagrass because it requires too much care and is often invaded by winter weeds.

A few lesser-known grasses are making their way into lawns. Selected hard fescues, native to the Canadian Rockies, grow so slowly in the cool climates that they hardly need mowing. Breeders have developed perennial ryegrasses that are very dark green; a few of these new cultivars even creep a little. In warm climates, bahia grass is sometimes used near salt water since it tolerates salt spray.

Measuring the Lawn

Whether you are planting a new lawn or rejuvenating an old one, an accurate measurement of your lawn's surface area can help you estimate how much seed, sod, or fertilizer you will need. In lawn grass lingo, materials estimates for seed or soil amendments are usually given per 1,000 square feet of surface area. Sod is sometimes sold in square yards. To measure the surface area in square yards, first determine your square footage and divide that figure by 9 for your square yard measurement.

Most houses are square or rectangular, and lawns mimic this design. To measure, divide the lawn into adjoining squares and rectangles, and measure the length and width of each. Multiply the length by the width of each unit to find the area of each section. Add these numbers together to find your lawn's total surface area.

Round or triangular-shaped sections of lawn may be measured using standard geometric formulas. To obtain the surface area of a circle, measure the distance from the center to the edge (the radius). Multiply this number by itself (for example 10 x 10); then multiply the answer by 3.14. The result is the surface area. To find the area of a triangular section of lawn, multiply the length of the base by the length of the height; then multiply the resulting number by .5.

You can calculate the surface area of irregularly shaped lawns by dividing them into their component parts—triangles, half-circles, or rectangles. Determine the area of each part; then add the figures together to find the total surface area.

How to Measure an Amoeba

To measure odd shapes with curved edges, find the approximate center of the space. Then measure a line drawn between opposite edges through the center. Divide this line into 10-foot sections. Then, at each 10-foot mark, determine the width of each 10-foot section by measuring the distance between opposite edges (perpendicular to the original axis line). To obtain the surface area, add all the widths together and multiply the total by 10. If your yard includes island beds within the lawn, use this procedure to measure the surface area of your beds, and subtract them from the total lawn area.

Sowing Grass Seed

Even the highest quality grass seed will result in a spotty, sunken lawn if it is sown into rough, unimproved soil. Preparation for seeding a lawn may be a laborious process, but is well worth the effort, for a properly planted lawn will thrive for many years.

In general, warm-season grasses are best seeded in late spring, while transitional and cool-season grasses are seeded in early spring or early fall. If you must do something with your bare yard but the time for planting expensive seed is months away, do some preliminary leveling and sow the site lightly with annual ryegrass. The cover crop can be tilled into the soil along with other soil amendments a few weeks before planting.

Preparing the Seedbed

A raw site around a new home generally requires considerable grading before it's ready to sow. You'll need to fill in low spots and even out high ones. Don't be in a rush to get started, for it will take several heavy rains to settle in loose dirt and reveal the true contours of your new yard. Once your yard is settled, fill in the low spots with excess topsoil from high places, or buy a load of topsoil for this purpose.

Incorporate weed-free, humus-rich organic material, like compost, well-rotted sawdust or manure, peat moss, or leaf mold, into the soil by spreading a 2- to 3-inch layer and using a rotary tiller to work it in. Organic matter will improve the drainage of heavy clay soils and the nutrient-holding capacity of sandy ones. Add organic fertilizers such as bonemeal, cottonseed meal, greensand, and ashes. Add lime, if indicated by a pH test.

Rake out debris, and smooth out the surface once more. Do not attempt to seed lawn-quality grasses on steep slopes. Plant sod instead, or use the slope to achieve some other landscape effect. For example, you might plant the slope with low, spreading shrubs, or create a small rock garden around a stone retaining wall.

When the site of the future lawn is raked smooth, the soil should be firmed into place. You can rent a lawn roller, or

Kentucky bluegrass
St. Augustinegrass
Bermudagrass

How High to Mow

As a general rule, cut grass at the high end of the range during hot weather; lower when weather is cool or plants are growing in shade. At the end of the growing season, cut the lawn back one last time at the lowest recommended height.

Grass Cutting	Height (in.)
Annual ryegrass	2–2½
Bermudagrass	1–1½
Centipedegrass	1–1½
Fine fescue	1½–2½
Kentucky bluegrass	2½–3
Perennial ryegrass	1½–2½
St. Augustinegrass	2–3
Tall fescue	2½–3½
Zoysiagrass	1–1½

you can use a large metal barrel, turned on its side. Roll over the area twice, until your feet leave only shallow prints in the seedbed.

Spreading Seed

You can use a mechanical seeder, available from rental centers, or spread seed by hand. The best way to ensure even distribution of seed is to make two applications. Take half of the seed and spread it while walking back and forth across the plot in parallel lines or strips. Make a second application with the rest of the seed by walking and sowing strips that are perpendicular to the first seeding. Rake lightly to barely cover the seed, and roll the area one last time to firm in the seeds and make sure there is good seed-soil contact. A light covering of weed-free straw (not hay, which contains weed seeds) will help retain moisture and keep the seed from washing away. If the site slopes more than a little, use burlap or cheesecloth to keep the soil and seed in place.

Aftercare

Grass seed needs good light and constant soil moisture for strong germination. Keep leaves and other debris off newly seeded lawns, and use a sprinkler to keep the soil evenly moist at all times for two to three weeks. Most grass seed

A Guide to Selected Lawn Grasses

One of the best ways to develop a low-maintenance lawn is to select the right grass for your region. Cool-season grasses are best for the northern part of the country; warm-season grasses for the Southwest and Sun Belt. Transition zone gardeners should use a mixture of both warm- and cool-season grasses for best results.

Name	Description	Culture	Rate of Establishment	Nitrogen Needs
Cool Season				
Kentucky bluegrass (*Poa pratensis*)	Lush, green with fine texture Good wear tolerance.	Moderate drought tolerance. Plants become drought resistant; require regular irrigation to stay dormant during periods of green in summer. Fertile, nearly neutral soil with plenty of sun.	1 year from seed; 6 months from sprigs; 3 weeks from sod.	Average; fertilize in early spring and early fall.
Fine fescue (*Festuca spp.*)	Dark green color and fine texture. Blends well with Kentucky bluegrass. Very good wear tolerance.	Good drought tolerance, especially in shady spots. Grows best in fertile, slightly acid soils.	1 year from seed; 6 months from sprigs; 3 weeks from mixed-species sod.	Below average; fertilize in early spring and early fall.
Perennial ryegrass (*Lolium perenne*)	Very dark green grass with fine leaves. Somewhat clumpy unless blended with bluegrass or creeping fescue. Blends well with bluegrass or creeping fescue. Very good wear tolerance.	Good drought tolerance. Plant in slightly acid soil in full sun.	2 months from seed, but expect 2 years for mixed-species lawn to assume mature appearance.	Average; fertilize in early fall.
Transition				
Blue gramagrass (*Bouteloua gracilis*)	Medium-fine grass with bunching habit. Forms dense sod. Good wear tolerance.	Warm-season grass often planted in transition zone and Great Plains. Drought tolerant. Good for cool, dry regions. Alkaline soil. Turns brown in severe drought.	2 years from sod.	Below average; fertilize in late spring and early summer.
Buffalograss *(Buchloe dactyloides)*	Native American grass with fine leaves and creeping stolons. Good wear tolerance.	Warm-season grass good for Great Plains and transition zone. Excellent drought tolerance. Will grow in full sun, clayey soil, and alkaline conditions. Turns brown in midsummer and again in fall.	2 years from seed, 1–2 years from plugs.	Below average; fertilize in late spring and early summer.
Fairway created wheatgrass *(Agropyron cristatum)*	Vigorous bunchgrass with deep, spreading root system. Good root system. Good wear tolerance.	Cool-season grass good for transition zone and Great Plains. Drought and cold tolerant.	About 1 year from seed.	Below average; fertilize in early spring and early fall.
Turf-type tall fescue (*Festuca elatior*)	Medium green grass, with coarse leaves. Noncreeping habit. Good wear tolerance.	Cool-season grass often grown in transition zone. Good drought tolerance. Will grow in many soils and tolerates a wide pH range.	3 months from seed.	Average to below average; fertilize in spring or fall.
Warm Season				
Improved bermudagrass (*Cynodon. dactylon* hybrids)	Medium to dark green grass with fine, stiff leaves. Excellent wear tolerance.	Excellent drought tolerance. Plant in fertile, well-drained soil with full sun.	2–3 months from sprigs; 3 weeks from sod. Seeding not recommended.	Above average; fertilize in late spring and midsummer.
Centipedegrass (*Eremochloa ophiuroides*)	Medium green grass with somewhat coarse leaves. Thick creeping stolons. Fair to poor wear tolerance.	Excellent drought tolerance. Will grow in moderately fertile, acid soils. Plant in full sun.	1 year from sprigs; 2 years from seed.	Below average; fertilize once a year and supplement with iron sulfate improves color and vigor.
St. Augustinegrass *(Stenotaphrum secundatum)*	Dark green grass with creeping stems and broad, flexible blades. Fair wear tolerance.	Average drought tolerance. Plant in fertile, well-drained, sandy, neutral to slightly acid soil. Can grow in shade.	3 months from sprigs or plugs. Not available as seed.	Above average; fertilize in early spring and fall to improve color and vigor.
Zoysiagrass *(Zoysia spp.)*	Medium green, creeping grass with fine, stiff leaves. In the north, turns brown in winter. Very good wear tolerance if thatch is removed every few years.	Average drought tolerance. Plant in full sun with fertile, well-drained slightly acid soil.	2 years from sprigs; 2 months from sod. Seeding not recommended.	Below average; fertilize once a year in late spring.

germinates within two weeks, but bluegrass, buffalograss, and centipedegrass are slower to start. In bluegrass/perennial ryegrass lawns, cut the lawn for the first time about two to three weeks after sowing to help the bluegrass compete with the more vigorous perennial ryegrass.

Planting Sod

Sod may be the perfect solution for high-traffic areas, slopes, and other problem areas. Although it costs more than seed, sod is attractive from the start and becomes established quickly. In some cases, the best grass cultivars are available only as sod. Another advantage is that sod can be planted nearly any time of year, although it is sensitive to drought and must be watered faithfully until it's established. Late summer to early fall is the best time to sod cool-season grasses in the North; late spring to early summer is best for warm-season grasses.

When buying sod, look for fresh, green slabs that have been kept constantly moist. Like seed, sod is available in mixtures of cultivars suitable for different regions. Buy only from nurseries that label the mixture and certify that it is free of weeds, insects, and disease, or arrange to buy freshly dug sod from a reputable nearby sod farmer. It's important to keep the sod moist once it's been delivered to you. It's best to prepare the soil before your sod is delivered so it can be planted as quickly as possible.

To plant sod, begin by preparing the site as if you were planting seed. Level it, add soil amendments, and rake away all debris. Sod cannot be planted over an old lawn. Where grass, weeds, or any plant material is present, dig it out or till it under before planting your sod.

The day before you plan to plant, roll the prepared site and water it lightly. Firm contact between soil and sod roots is essential, so check to make sure all weeds and other debris are cleared away.

Laying Sod

Begin laying the sod against any straight edge, such as a sidewalk or a string stretched between two pegs. Lay the sod in strips, end to end, and fit them together as tightly as you can without overlapping. To prevent erosion, stagger the seams or edges of the pieces to achieve a bricklike pattern. Trim away excess sod along curved or uneven edges with a sharp knife or shovel. You can use the pieces you cut away to fill in elsewhere or to rejuvenate dead spots in another part of your lawn.

Once the sod is in place, roll it to firm the roots into the soil. Fill crevices between sod pieces with weed-free topsoil—use a broom or the back of a wooden rake to do the spreading—and turn on the sprinklers. All types of sod should be thoroughly soaked right after planting, then twice a week for three to four weeks thereafter.

Planting Plugs and Sprigs

Some creeping grasses are planted as small pieces of sod called plugs or sprigs. Plugs are small, container-grown pieces of sod; sprigs are individual rooted grass stems made from shredded sod. Unlike conventional sodding, plugs and sprigs are spaced from 6 to 12 inches apart, with bare areas in between. This technique is most often used with warm-season grasses such as St. Augustinegrass, bermudagrass, centipedegrass, and zoysiagrass. Any type of sod can be cut into chunks and planted as plugs. For most grasses, this isn't a recommended practice for large areas because they spread less quickly than the species commonly planted in this manner.

Plugs and sprigs are best used for planting lawns that are level and in low-traffic places. When planting a lawn in this manner, keep in mind that several months may pass before the grass plants grow together completely. On slopes, heavy rains will wash away the soil between the plugs or sprigs, and the end result will be a spotty, uneven lawn. Weeds often appear in the areas between the plugs or sprigs and must be hoed out or pulled by hand.

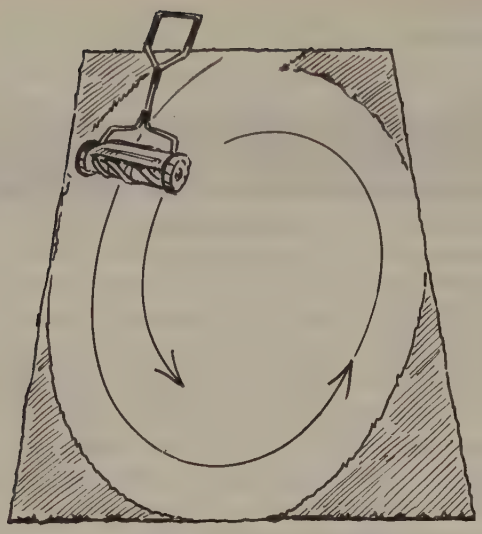
For best results, plant plugs or sprigs in spring. Prepare the planting area as you would for seed or sod, but leave the soil loose instead of rolling it. Both plugs and sprigs dry out quickly, so keep them in a shady place and sprinkle them with water frequently until you are ready to plant them.

Plugs should be planted at their normal growing depth, 6 to 12 inches apart. With sprigs, lay the pieces in shallow furrows at an angle so that two-thirds of each sprig is buried and only a tuft of grass shows above the ground. An alternate way to plant is to drop the sprigs at intervals on the surface of the planting area, and push them into the soil with the heel of your shoe. After planting, roll the area to make sure the soil is firm and level and roots are in good contact with the soil. Then water the area thoroughly, and keep it damp for at least three weeks. Hoe out weeds as soon as they appear, and topdress with a good organic fertilizer when rapid growth commences.

Mowing the Lawn

Each time you mow your lawn, you actually are pruning back thousands or millions of grass plants. Mowing does much more than make it possible to walk to your car in the morning without getting your feet wet. When properly done, it helps expose the crowns of the plants to sunlight and encourages the development of tillers, or creeping stems.

Continued →



Mowing in a round or oval pattern saves time and effort, because you don't waste energy turning sharp corners.

The rule of thumb is to remove one-third of the grass's top growth each time you mow. Mow too high and you'll need to mow again in a few days; mow too low and you may send the grass into a state of shock by exposing the crowns of the plants to sun and cutting off too much of the leaf blades, which manufacture food for the plants. Close cutting also helps create places between grass plants where weeds can become established. Adjustments may be made to mowing heights, depending on the season. In midsummer, it's a good idea to mow higher than normal since long blades help insulate the plant's crowns from moisture loss. In early fall, warm-season grasses are sometimes cut very low and overseeded with annual rye for better winter color.

Always mow when the grass blades are dry. Sharpen mower blades at least yearly so that they slice off the tops of the grass cleanly instead of chewing it up. Rotary mowers (the most popular kind) are fine for most lawns. Reel-type mowers are recommmended for very dense, fine-bladed grasses like zoysiagrass and hybrid bermudagrass.

Thick clumps of grass clippings may be gathered and used as mulch or added to the compost pile. Let light layers rot where they fall; they are a good source of nitrogen, and nature will take care of recycling the nutrients in the clippings.

Rejuvenating Lawns

Sooner or later, most lawns need a face-lift—either of the entire lawn or of small patches that have been damaged by insects, weeds, or diseases. Many old lawns can be renovated in a weekend, though more work is in order if weeds are running rampant (in which case, it is probably best to start again from scratch) or if the soil is badly compacted as a result of heavy use.

The first step in any lawn rejuvenation project is to dig out the weeds—roots and all. For an all-over face-lift, once weeds are under control, the next step is to rent a vertical mower, also called a dethatcher. Healthy lawns have about ¼ inch of thatch, the undecomposed organic matter on top of the soil, which acts as a mulch and helps conserve moisture. Heavily fertilized lawns can build up thick layers of thatch that smother the plants and create ideal conditions for insects and disease. A vertical mower cuts small slits in the turf and brings dead plant parts to the surface where they can be raked up and composted. Dethatching gives old grass new room to grow and opens little places in the turf where new grass seed can germinate.

If the soil appears hard and lifeless, some type of aeration also is in order. You can rent power aerator machines that poke holes in the turf or other machines that cut out small cores of soil. In addition, a generous topdressing with a good organic fertilizer will aerate the soil in the most natural way, by encouraging the proliferation of soil microorganisms. Fertilize after dethatching and aerating. This is also the time to apply lime, if indicated by a soil test.

Seeding or Patching

The lawn is now ready for overseeding or for patching with small pieces of sod. In bluegrass lawns, simply overseed the old, reconditioned lawn with a mixture of updated cultivars, and keep the area moist for three weeks. Fescues, perennial ryegrass, and other seed-sown lawns also may be overseeded in this way.

Grasses that cannot be sown from seed, such as zoysiagrass and the new hybrid bermudagrasses, often respond to reconditioning so dramatically that no further planting is necessary. However, bare spots formerly occupied by weeds should be planted with pieces of sod taken from the outer edges of the lawn.

Starting from Scratch

If you want to completely renovate your old lawn and plant a new type of grass, the entire site should be tilled up and raked clean, a major job that you may want to hire someone to do. To get rid of the old grass, you can slice it away and pull it up in strips, or till it under. (You may need to till two or three times to be sure the old grass won't come back.) In hot weather, it is sometimes possible to heat-kill areas of unwanted grass by covering them with clear plastic for several days. Decrease the chances that the grass will survive by mowing it as low as possible before tilling it under. Whatever you do, don't rush to replant; be sure the old grass is dead before proceeding. Expect to wait several weeks before the site is ready for replanting.

The Organic Lawn

Roger Yepsen

You can eliminate or greatly reduce the synthetic fertilizers and pesticides used on your lawn. And that will mean one less source of worry about the health of your family, pets, and the home environment. While chemical-based lawn care treats the soil as a passive blotter, the organic approach focuses on improving the lawn from the ground up. Good soil gives rise to healthy lawns, with less trouble from pests, diseases, and adverse weather conditions. You also may find that the lawn has a reduced need for watering and fertilizer.

Working with an Existing Lawn

Unless you're moving into a new home, or are expanding your lawn into what had been a field or garden beds, you probably are looking at a reasonably well-established lawn. You can bump up its appearance a couple of notches by core aeration, adjusting mowing height, and top-dressing with a fine, sifted compost.

Increasing the level of organic matter will improve the soil's structure, with a few benefits. The soil will be better able to hold on to moisture and nutrients, while promoting good drainage. Roots will grow more easily, so that the grass will hold up better against an assault from weeds. Finally, organic matter contributes to nitrogen fixation and helps resist soilborne plant diseases.

All of this won't take place overnight. While chemical approaches can have an almost immediate effect, organic improvements are gradual. And you'll be a happier homeowner if you don't expect a totally weed-free lawn. A yard that is a bright, flawless green throughout the year is probably a lawn heavily reliant on chemical help and a lot of irrigation. The organic way involves a more relaxed perspective.

Keep Sharp

The whirling blade of a mower is out of sight, and it tends to be out of mind as well. But if it has become dull, it may be beating the grass into submission rather than cutting it cleanly. Inspect the ends of a few clippings. If they are frayed, that's a sign that the blade needs attention. The entire lawn may take on a somewhat brownish tinge. A dull blade also puts a greater load on the mower, consuming more gas and contributing to wear and tear. Shredded grass may be more susceptible to lawn diseases. Finally, the blade has to be sharp in order to cut damp grass without serious tearing.

Sharpening a blade isn't an easy task, no matter what the operating manual for your mower may suggest. You have to make sure the engine won't start up while you're removing the blade, and that means knowing where the spark plug is and how to remove the wire running to it. Getting at the blade is a challenge if you have a riding mower. And even a dull blade can cut you, meaning you need to be mindful when removing it. Finally, a blade may need routine balancing as well as sharpening, and that's a job beyond the skills and aptitude of most homeowners. The easiest solution is to have the mower dealer pick up the machine and do the sharpening, as well as balancing the blade if necessary. Second easiest is for you to deliver the mower. If you have no way of transporting a riding mower and the pickup charge is prohibitive, you can follow the operating manual's directions for removing the deck, then take it to the dealer.

Lawns the Low-Maintenance Way

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

Lawn grasses and groundcovers go hand in hand in the low-maintenance landscape. Nothing beats a lawn for a durable place to play or a smooth, green swath to set off flower beds. But lawn grasses perform best in full sun on fertile, well-drained soils. That's where groundcovers come in. Nothing beats them for care-free plantings on tough-to-mow sites—or to reduce high-care grass.

In this section, you'll learn how to reduce the time you spend on your lawn by examining your equipment, grass choices, and routine care. You'll also find out how modifying old habits will help you cut lawn care. Finally, you'll learn to recognize parts of your landscape better suited for groundcovers than for turf grasses.

Keep Grass in Check with Edging and Mulch

A vigorously growing lawn will grow right into your flower beds and up to the bases of trees and shrubs if you don't control it. Neither your trees and shrubs nor your lawn benefit from the resulting competition. A combination of an edging barrier and mulch around plants and plantings will keep the grass where you want it. It will also protect other plants from too-close encounters with mowers and trimmers.

To install edging strips, start with thick, good-quality edging; you'll find a variety of edging strips at local garden centers and nurseries. Thick edging is easier to install and will last the longest. Deeper edging stays in the ground better. Here's how to go about installing your edging.

1. Use a garden hose, rope, or a line drawn with sand or lime to outline the area you want to edge. Keep curves gentle and avoid sharp corners.
2. Use straight pieces of plastic edging if possible. Warm coiled edging in the sun for easier straightening.
3. Dig a straight-edged trench that's as deep as your edging. To save yourself work on a large installation, consider renting a power trencher.

Continued →

4. Working from one end, loosely install the entire length of edging with the rounded edge just above the soil line. Backfill just enough to hold the edging in place. The edging should stay in the trench without any pressure. Tight curves or forced fits will pop out later.
5. Inspect the installation, make any minor adjustments, then backfill and firm the soil around the edging. Water the area thoroughly for uniform settling and firming.
6. Check edging strips annually to make sure spreading weeds or grass haven't grown over them. Mow over the top of the strip, with one wheel in the bed and one in the lawn. This lets you mow and trim at the same time. Keep the garden mulched to control spreading weeds.

Methods to Help You Tame the Mowing Monster

Most of us give up far too much of our limited free time to cutting grass. But if you want a traditional-looking lawn, mowing is a necessary evil that can consume large portions of your time from spring to fall. Short of giving up your lawn entirely, there are ways to make mowing easier, quicker, and more efficient.

The amount of time you spend mowing is a direct result of the vigor and layout of your lawn, as well as the kind of mower you use. Since a healthy, vigorous lawn can grow fairly aggressively, you're more likely to reduce mowing time by mowing more efficiently than by mowing less often. Try any or all of the following tips to make your mowing quicker and easier.

Repair or replace awkward spots. Level out rough spots in your lawn to allow your mower to travel more easily. Keep grassy areas at least three times the width of your mower to allow for easy turning. Fill smaller or tough-to-mow sites with groundcovers.

Mow frequently. Mow often enough to remove no more than one-third of the leaf blade at one time. Frequent mowing reduces clipping clutter, snips of germinating weeds, grinds leaves, and promotes dense turf. The mower will move quickly over the lawn, too.

Mow high. Set your mower blade to a height of about 2½ inches for most grasses; higher for fescues and St. Augustine grass. Tall grass smothers prostrate weeds, captures more sunshine, and roots more deeply to reach nutrients and water.

Use the proper tool. A properly sized mower with adequate power will speed up the mowing process. It's also a pleasure to use equipment that performs a chore quickly and easily.

Let clippings lie. Save yourself work and return moisture and nutrients to your lawn: Let cut grass lie where it falls.

Add water during dry spells. Water enough to keep the grass alive during droughts without bringing it out of heat-induced dormancy. Drought stress makes lawns susceptible to invasion by weeds, diseases, and pests. When watering is necessary, apply 1 to 2 inches by recording the time it takes for your sprinkler to fill a pan to that depth. Select sprinklers that adjust for complete coverage and distribute a large quantity of water quickly. Use programmable timers to water late at night when water pressure is high and winds are minimal.

Avoid overfertilizing. The lush new growth that results from generous applications of nitrogen is disease-prone and requires frequent mowing. A healthy lawn may get by with little more than the clippings produced when you mow, plus one or two top-dressings with compost or other organic fertilizer each growing season.

Accept and encourage diversity. Diseases, insects, and other stresses have less impact on lawns that have a mixture of grasses, along with weeds like clover.

Eliminate obstacles and trimming. Shape plantings and borders so you can guide the mower around them without excessive turning or stopping.

Consolidate plantings. Plant shrubs and trees in groups and mulch or plant beds of groundcovers around them. It's much easier to mow around the edge of a group of plants than to mow around each plant individually.

Prune offending branches. Ducking and dodging as you mow slows your progress and is dangerous—you're not paying attention to your mower if there's a tree branch in your face. Keep trees and shrubs pruned appropriately to give you access with the mower, or plant no-mow plants beneath obstructing limbs.

Make follow-up trimming obsolete. Use perennials and groundcovers that hang over the edge of the lawn around tree trunks or along buildings. Let your mower's deck slip under the overhanging leaves to cut the grass right to its hidden edge. Install mowing strips around plantings to eliminate trimming after you mow.

Minimize Frustration with Regular Mower Maintenance

Few things are as frustrating as having a lawn in need of mowing and a mower that won't work. Performing regular maintenance on your mower or having a mechanic maintain it for you is a small investment that can prevent major mowing headaches.

Check the oil. Do this while the mower is on level ground, before you start the engine. Fill to the appropriate level for your mower's engine. Change engine oil when it's warm—contaminants are suspended and the oil will flow easily.

Keep filters clean. Clean foam filters in warm, soapy water. When they're dry, squeeze enough oil through them to lightly coat the entire filter. Gently tap and blow dirt out of pleated paper filters. Replace them when the paper discolors significantly.

Keep belts and chains snug. Check belts for cracks or glazing. Keep spares on hand even if you don't change them yourself so you don't have to wait for parts to be ordered and shipped.

Keep the mower clean. Use a leaf blower or shop vacuum to remove dust and debris from the mower deck and engine compartment. While you wash the mower, look for loose hardware or other potential problems. Avoid getting water on ignition parts, or the mower will have to dry before it will start.

Lubricate chains, bearings, and bushings. Check the owner's manual for locations and lubricant specifications.

Keep blades sharp. Sharp blades cut cleaner with less power. Removing the blades frequently for sharpening will keep them from becoming stuck on.

Speed Mowing Time with a Bigger Mower

If you have a large lawn to cut, buying a bigger mower is a straightforward way to reduce the time you spend mowing. And a larger mower with a larger engine will do the job more efficiently than a small machine that's running for a longer time.

When shopping, consider overall mower size, deck size and location, maneuverability, engine size, comfort, and cost. Mower features to consider as you shop include cutting deck placement, the power source that moves the mower (you or the engine), pull start vs. electric start, the engine's capacity relative to the work it has to do, and overall comfort and ease of use. Use this list of mower types to help you find the mower that's right for you and your lawn.

Mulching mowers. Mulching mowers (or mulching modifications to bagging mowers) chop clippings and leaves into fine pieces, reducing grass residue and allowing easier cleanup. They don't work well in grass that is too tall or wet.

Bagging mowers. These machines pulverize grass, leaves, and debris while vacuuming the lawn. Bagging takes more time than allowing the clippings to fall back on the lawn, but it provides a useful material for mulching or composting. Look for bags that are large, easy to put on and take off, and easy to empty. Find a mower that bags when necessary, but also mulches or discharges effectively.

Intermediate mowers. Sized between homeowner models and mowers used by maintenance crews, some intermediate mowers offer a sulky option and may be used either as a large walk-behind or a rider.

Riding mowers. Riding mowers generally have larger decks than their walk-behind counterparts and travel faster than a comfortable walking speed. Riders come in different sizes and configurations, so find one that meets your specific needs.

Quit Vacuuming Your Lawn and Feed Your Soil Instead

Leaves or clippings can smother lawn grasses; but you don't have to spend hours vacuuming or raking them up and hauling them away. Instead, use your mower to grind them up into small particles so they can settle into the soil and decompose. You'll not only eliminate most raking, but you'll also be enriching the soil with organic matter.

You can actually treat your lawn like a giant sheet composting site. Throw anything the lawn mower will handle onto the lawn, then pulverize it. Rake up resistant material when you're finished and remove it to the compost pile. Use these tips to make the most of your mower as a soil-enriching power mulcher.

Mow often. Take care of leaves before they build up and clog the mower. The added mowing time is minimal, and you'll no longer have leaf disposal.

Keep the blade sharp. A sharp blade pulverizes effectively.

Clean the air filter frequently. Dry, dusty leaves will plug the filter quickly. Make sure that you clean your filter often, especially after mowing leaves, which produce more dust.

Circle inward. Use a side-discharge mower to blow leaves into a row, then mow the row to grind the leaves into tiny pieces and disperse them to the outside over the lawn.

Circle outward. For heavy leaf cover, start in the middle of an area and discharge the leaves to the outside for dispersal or pickup around the edges.

Make light work of leaf lifting. If you need to rake up leaves, rake them onto a large tarp for easy transport. Leaves are light when dry; grab the corners of the tarp to tote large quantities.

Keep Weeds at Bay by Reseeding

Keep weeds from colonizing your lawn by reseeding bare or sparsely covered patches. For best results, seed in late summer when soils are warm and weed seed has already germinated. Here's how.

Remove existing vegetation. Remove weeds and existing grass with a sharp spade, sod lifter, or scuffle hoe. Rough the soil to a depth of at least 1 inch, using a rake or cultivator for small areas and a rotary tiller for large ones. Level the soil with the surrounding area, then rake from several directions to make many crossing furrow lines. Grass seed germinates best in grooves, so make plenty of them.

Sow your grass seed. To increase germination, protect the seed from hungry birds, and prevent it from washing away in rain, lightly mulch the area with straw. Or tack a floating row cover over the seeded area with rocks or bent lengths of wire until the grass begins to sprout. Water gently to wet the top ½ inch of soil, then keep the area moist, but not soggy, until your seedlings are ready for mowing.

Mow when most of the area needs it. Don't wait too long to mow or taller grass will shade the remaining new seedlings. After three mowings, treat the newly seeded area like an established lawn.

Grow Grasses You Can Count On

Whether you are installing a new lawn or renovating an existing one, use the following tips to select the best grass for your lawn.

Continued →

Suit your local growing conditions. Northern, cool-season lawns are commonly composed of bluegrass, ryegrass, or fescues. Warm-season lawns most often contain zoysia, St. Augustine, centipede, bahia, and bermuda grasses. Check with your county's extension office or garden centers to get up-to-date recommendations on the best grasses for your area.

Pick the best cultivars. Look for lawn grass cultivars with drought tolerance, disease resistance, and other low-maintenance characteristics. There are also dwarf or slow-growing cultivars that need less mowing.

Plant endophyte-enhanced grasses. For a lawn that resists pests, try a grass that contains endophytes, fungi that live in plants without causing harm. In grasses, these fungi confer resistance to leaf-eating pests like chinch bugs, sod webworms, and armyworms. Cultivars of fine fescues, tall turf-type fescues, and perennial ryegrasses are currently available. Choose seed mixes that contain at least 50 percent endophyte-enhanced seed for maximum protection; buy fresh seed to ensure that the fungus is viable.

Your Seasonal Lawn-Care Calendar

JANUARY

Cool Grass:

Check out the reel mowers in your local hardware store. (If the store doesn't carry them, tell somebody in charge that they should!) Winter's also a great time to think about how you use your yard and plan a project to convert some lawn to another use such as a meadow, island bed, or outdoor entertaining area.

Warm Grass:

Add lime or sulfur to correct pH, if recommended by soil test. Also, winter is a great time to think about how you use your yard. Why not plan a project to convert some lawn to another use?

FEBRUARY

Cool Grass:

Sharpen your mower blades, or take them to a nearby shop to have them sharpened. Now's a good time for a mower tune-up, too—you can beat the crowds. A properly working mower will generate less pollution. While you're at it, set your mowing height at 3 inches or higher.

Warm Grass:

If you have a power mower, take it in for a tune-up ahead of the spring crowds. Sharpen your mower blades, and consider buying a spare blade so you'll always have sharp blades on hand.

MARCH

Cool Grass:

Clean up any debris left on the lawn after the winter.

Warm Grass:

Your first mowing should be in early spring. The mowing height depends on the type of grass you're growing.

APRIL

Cool Grass:

As the grass begins to grow, you can begin to mow—but don't remove more than one-third of the height of the grass blades at each mowing. You might want to bag or rake up the clippings after the first mowing to add a good dose of nitrogen to your compost pile. But after that, leave the clippings on your lawn!

Warm Grass:

Warm-season grasses are actively growing now, so water as necessary during this season of growth, and keep on mowing.

MAY

Cool Grass:

Spread organic fertilizer. There's not much point in doing this before mid-month, as it won't begin to act until the soil warms. Water as necessary during the grass's active growing season. Deep watering, enough to wet 6 inches down into the soil, encourages healthy roots. Mow weekly or even every five days if your grass is growing rapidly.

Warm Grass:

In addition to mowing, spread organic fertilizer. Different grasses have different nitrogen requirements.

JUNE

Cool Grass:

Mow and water—but only as needed. Watch for changes in your lawn. If it changes from green to yellow, that means it's entering

semidormancy. Don't worry—this is normal! You shouldn't try to revive it by watering or fertilizing. Your grass will come back in the fall—it's only resting.

Also, examine your lawn for clues about your soil. For instance, clover is a sign that your soil lacks sufficient nitrogen.

Warm Grass:

Continue to mow and water as necessary. Make mowing easier on yourself by resharpening your mower blades. Bahiagrass especially requires sharp blades. Plug or sod bare areas.

JULY

Cool Grass:

Sharpen your mower blades—yes, again! A sharp blade causes less stress to the grass. Besides, your lawn is growing so slowly that you can mow as infrequently as every three weeks (especially if the weather is dry), so you'll have plenty of time to devote to sharpening.

Warm Grass:

Continue to mow and water your lawn as necessary.

AUGUST

Cool Grass:

Test your soil, especially if you think your lawn needs help. How much topsoil do you have? Check and see: 4 inches is good—6 is better. Continue mowing, but only as needed.

Warm Grass:

Make a second application of organic fertilizer. If you're waiting for plugs or sprigs to fill in your lawn, get out the hoe and take care of any weeds that are filling in faster than your grass. Mow and water as necessary.

SEPTEMBER

Cool Grass:

This is a busy month! Look at all you can be doing to care for your lawn.

- If your lawn has bare spots, seed them now.
- If your lawn is sparse or if you'd like to overseed with a pest- or disease-resistant grass species, reseed now.
- Spread organic fertilizer or a thin layer of sieved compost.
- And of course, mow and water as necessary as your grass is actively growing.

Warm Grass:

Don't stop now! Continue to mow and water as necessary.

OCTOBER

Cool Grass:

If your soil test indicated that you need to raise the pH, add lime. If your pH is too high, consider adding sulfur. Mow only as needed, the growing season is nearly over.

Warm Grass:

Warm-season grasses are entering dormancy, and you can begin to slow down, too. Cease irrigation as the growth stops.

NOVEMBER

Cool Grass:

Mow over fallen leaves to chop them up. Rake the chopped leaves if the cover is very thick (for example, under a Norway or sugar maple) and save them to use next spring as mulch. Often you can get away with just leaving them on the lawn, where they'll decompose and add nutrients. When you mow for the last time this season, mow your lawn shorter than usual.

Warm Grass:

Test your soil to determine pH and soil deficiencies. Then take a break from lawn care!

DECEMBER

Zzzzzzzzzzzzz.

Whether you grow cool- or warm-season grass, your lawn is reating, so you can, too!

Lawn-Care Glossary

Aeration. Boring holes in the soil with a special tool or a spading fork to open up spaces in it so that oxygen, water, and nutrients can reach grass roots. It is generally ineffective and unnecessary in a healthy lawn, although it may help lawns growing in heavy clay soil.

Clay soil. Soil that is made up of very fine particles that hold nutrients well but are poorly drained. Clay soil is heavy and difficult to work.

Compost. Decomposed and partially decomposed organic matter that is dark in color and crumbly in texture. Used as an amendment, compost increases the water-holding capacity and drainage of the soil and is an excellent nutrient source for microorganisms, which later release nutrients to your plants.

Cool-season grass. Any grass species that grows well in spring and fall (such as Kentucky bluegrass or fescue) but grows slowly or goes into a dormant state in the heat of summer.

Continued →

Dethatching. Removal of excessive thatch with a dethatching machine or rake. Thatch buildup is caused by overfertilization, which can result in lawn grass growing at a faster rate than the soil organisms can break it down, and by the use of pesticides that kill earthworms, important decomposers of thatch. With good organic lawn-care practices, most lawns shouldn't need dethatching.

Endophyte. A naturally occurring fungus that lives inside some grass plants. It doesn't harm the grass, and endophyte-infected grasses are more resistant to insects and have better drought tolerance. Note: Endophytes are harmful to livestock, so don't plant endophyte-infected grasses in grazing areas.

Fertilizer. A natural or manufactured material added to the soil that supplies one or more of the major nutrients (nitrogen, phosphorus, and potassium) to growing plants.

Foliar feeding. A way to give grass a light nutrient boost by spraying plants with a liquid fertilizer that is absorbed through the leaf pores. Compost tea and seaweed extract are two examples of organic foliar lawn fertilizers.

Grubs. Larvae of beetles and other insects that overwinter in the soil, feeding on grass roots early and late in the season. You can recognize grubs by their white, C-shaped bodies; control them with milky disease spore.

Herbicide. A substance used to kill unwanted plants. Some types are selective (they kill only a certain type of plant); others are nonselective and will kill any plants they come in contact with. Corn gluten meal is one of the very few effective organic herbicides.

Humus. A dark-colored, stable form of organic matter that remains after most of the plant and animal residues in it have decomposed.

Hydroseeding. Establishing a lawn area by spraying a slurry, which is a mixture of grass seed, fertilizer, fiber mulch, and water.

Loam. The best texture of soil to have. It contains a balance of fine clay, medium-size silt, and coarse sand particles. Loam is easily tilled and retains moisture and nutrients effectively.

Named variety. A subdivision of a plant species that has been selected for its improved vigor, fine texture, or other desirable characteristics and then bred and named by the industry to ensure a standard of quality.

Nematodes. Microscopic, slender, translucent roundworms, many of which act beneficially as decomposers and pest parasites. Other nematodes feed on and damage plant roots.

Nitrogen. An element that promotes vigorous growth and healthy color and is one of the three main nutrients in a complete fertilizer. Plants can't use nitrogen directly from the air—it's converted naturally by soil microbes into a form that plants can absorb.

NPK. A recognized abbreviation that refers to the ratio of the three major nutrients—nitrogen (N), phosphorus (P), and potassium (K)—in fertilizer, such as 5-5-5 or 10-2-2.

Organic. Materials that are derived directly from plants or animals. Organic gardening uses plant and animal by-products to maintain soil and plant health and doesn't rely on synthetically made fertilizers, herbicides, or pesticides.

Overseeding. Renewing a lawn area by sowing seeds over an existing lawn without first clearing away existing sod. Overseeding is used to spruce up a weary lawn or to introduce disease-resistant grasses or a different grass species.

Pesticide. Any substance, synthetic or natural, which is used to kill insects, animals, fungi, bacteria, or weeds.

pH. A measure of how acidic or alkaline a substance is. The pH scale ranges from 1 to 14, with 7 indicating neutrality, below 7 acidity, and above 7 alkalinity. The pH of your soil has a great effect on what nutrients are available to your plants.

Plugs. Small pieces of sod of creeping types of grasses, or seedlings or cuttings of a groundcover. Plugs are generally planted 6 to 12 inches apart, depending upon how quickly they will grow together to cover an area.

Sandy soil. Soil that contains more than 70 percent sand and less than 15 percent clay. Sandy soil is usually well drained and easy to work with, but it has poor nutrient- and water-holding abilities.

Silt. Soil particles of moderate size—larger than clay but smaller than sand.

Sod. Strips of living grass held together by matted roots that can be laid on a prepared soil bed to create an instant lawn.

Soil test kit. A set of instructions and a soil bag available through your state's Cooperative Extension Service. Test results indicate soil pH and specify what amendments and nutrients should be added to your soil to ensure success with your planned use.

Spreader. A bin on wheels with an adjustable opening for spreading grass seed, fertilizer, or amendments evenly, usually over a lawn. Drop spreaders drop seed and fertilizer directly on the ground as you push them; broadcast spreaders spew the material in a radius up to 10 feet from the spreader.

Thatch. A layer consisting of the roots, stolons, and rhizomes of grass plants that fail to decompose. Thatch can accumulate to excess if the lawn has been overfertilized, or if earthworm populations have been reduced by the use of pesticides.

Topdressing. Covering the lawn surface with a thin layer of a soil amendment, such as finely screened compost, to improve or maintain soil health.

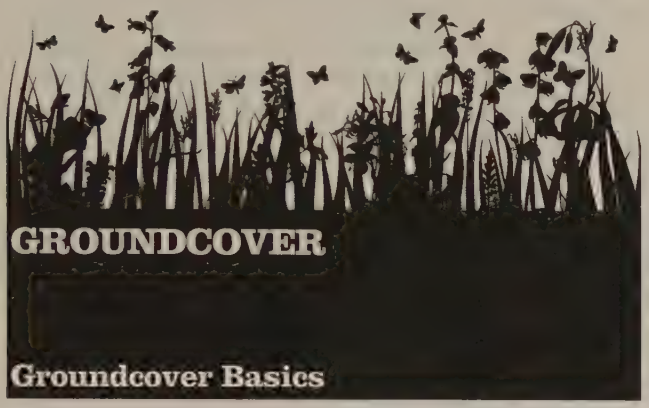
Transition zone. The geographical area where both warm- and cool-season grasses will grow, but where neither type is at its best.

Turfgrass. Grass varieties selected and bred for best performance as lawn grasses.

VNS. On a package or grass seed, VNS stands for "variety not stated" and indicates unspecified varieties of lawn seed. Grass grown from VNS seed is inconsistent in quality.

Warm-season grass. Any species of grass, such as bermudagrass or zoysiagrass, that grows well in summer, even in hot, dry climates, and is usually dormant in winter.

Weeds. Any plants that happen to grow where you don't want them to. Some perfectly fine plants can be considered weeds when they pop up in the wrong places.



Jeff Cox

Groundcovers are the original landscape problem solvers. Where lawn grass won't grow easily or well, groundcovers come into their own. You can use plants like pachysandra to cover bare spots in the dense shade and dry soil under trees. Choose tough, deep-rooted groundcovers like daylilies to stabilize slopes. Plant Chinese astilbes (*Astilbe chinensis*) or Japanese primroses (*Primula japonica*) in wet, boggy sites instead of mowing a quagmire.

For weed control and reduced yard maintenance, groundcovers can't be beat. But they're also excellent for covering up plants that are past their peak. For example, hostas will mask dying daffodil foliage so it can ripen in peace without becoming an eyesore. You can also use groundcovers like periwinkle (*Vinca* spp.) under spring bulbs, ferns, and perennials—its uniform green will set off taller and more colorful plants.

You can use any low-growing plant as a groundcover as long as it meets certain requirements: It should look attractive all season, spread quickly to carpet the ground, require a minimum of maintenance, and keep down weeds. Don't limit your choices to the obvious ivy, pachysandra, and periwinkle, though all three make excellent evergreen groundcovers. Wildflowers, perennials, ornamental grasses, annuals, and low shrubs can all be used as groundcovers. For most situations, choose plants that hug the ground or grow up to 3 feet tall; the most useful groundcovers are generally 6 to 18 inches tall.

Using Groundcovers

Why use groundcovers when you can just grow grass? For adaptability, resilience, and uniformity, you can't top lawn grasses. They withstand heavy foot traffic, rough play, and all the abuse a family can muster. However, it can require a lot of effort to keep lawn grasses healthy and attractive. They won't grow well under trees and shrubs or in wet sites. You'll save yourself time and work—and create a more dynamic landscape—if you reduce your lawn to the smallest size you need for outdoor activities and turn the rest of your yard over to groundcovers, decks, patios, and ornamental plantings.

Another good way to use groundcovers is to grow them in islands under trees. With a planting of groundcovers around your trees, you won't injure the trunks by scraping them with the lawn mower or waste precious gardening time hand-trimming around each trunk. A mixed planting of hostas, with their beautiful leaf patterns and colors, looks wonderful under trees. So do ferns and astilbes (*Astilbe* spp.), or try blue-green lilyturf (*Liriope* spp.) for a cool contrast to the lighter lawn grass.

Underplanting trees with groundcovers makes your landscape more interesting, too. You can tie individual plants together by surrounding them with an island of groundcover plants, or tie separate groups of plants together by underplanting them with the same groundcover. Try uniform or mixed plantings of groundcovers under shrubs and next to lawn areas, too. You'll find that your yard looks more appealing when everything looks connected—suddenly it will look like a landscaped garden, and all because of a few groundcovers!

You can also grow groundcovers instead of lawn grass where you want to limit water use. As anyone who's spent evenings or weekends holding a hose knows, lawns are very thirsty. Xeriscaping, a landscape philosophy based on water conservation and minimizing damage to the landscape, uses extensive plantings of tough, drought-resistant groundcovers. These adaptable plants reduce environmental impact, save water, and cut maintenance time.

Groundcovers also can perk up the landscape in the off season. Think about fall and winter in your garden. Many groundcovers take on beautiful hues as cool weather returns. Some, like lilyturf and bearberry (*Arctostaphylos uva-ursi*), display colorful fruits. Seed heads of ornamental grasses are loveliest late in the season. Evergreen foliage shines again light light snowfalls.

Don't forget to go beyond problem solving when you're using groundcovers—after all, you have to look at them, too. A yardful of pachysandra may get the ground covered, but it's not nearly as appealing as a combination of groundcover plants. Think about mixing shape, texture, and color in exciting combinations. Feathery ferns with white-variegated hostas and low, glossy-leaved European wild ginger (*Asarum europaeum*) will make a shady site much more interesting than any one of the three alone. A mix of ajugas (*Ajuga reptans*)—perhaps 'Pink Beauty' (a pink-flowered, green-leaved cultivar) with the bronze-leaved 'Bronze Beauty' and large-leaved, blue-flowered 'Catlin's Giant'—will add more sparkle to a sunny spot than a single cultivar.

Continued →

Don't be afraid to try something new if a combination falls flat. If a plant doesn't work where you've put it, just move it: Your best design tool is you shovel.

Choosing Groundcovers

The cardinal rule in gardening is to match the plant to the site. To get the best performance from a groundcover, you must give it the growing conditions it needs. Plant shade-loving, shallow-rooted Bethlehem sage (*Pulmonaria saccharata*) to cover a bare area in the shade of a maple tree, and sun-loving, deep-rooted yarrows (*Achillea* spp.) to stop erosion on a dry, sunny bank.

Don't forget maintenance. Plant rampant growers like ivies or sedums where you need dense cover to control weeds, not in a small space where they would quickly get out of control. For a small space that's not weed-prone, choose airy plants like Allegheny foamflower (*Tiarella cordifolia*) or chamomile (*Chamaemelum nobile*) that won't be in a hurry to overgrow the site. In both cases, a well-chosen groundcover will reduce your yard work, while a badly chosen groundcover will pitch you into a losing battle.

When you're looking for a good groundcover, let your needs limit your choices. Focus on the plants that suit your garden and your design. First, define your needs by asking yourself a few key questions:

- Is your site shaded, partially shaded, or in full sun?
- Is your site moist or dry?
- Do you need a ground-hugging plant for the site, or would a taller plant look better?
- Do you want bold or fine texture?
- How important are flowers? Flower color?
- Can you use variegated foliage to brighten things up?
- Should the plant you choose be evergreen or deciduous?

You'll find lists of groundcovers for special situations at the end of this section.

Planting and Maintenance

When you're trying to grow a good groundcover, thorough soil preparation is essential, especially in difficult sites. Plants will take off and grow faster if you give them a head start, so you'll have less trouble with weed competition. If you haven't had a soil test, consider it; you'll learn a lot about your gardening conditions.

First remove existing sod or undesirable growth from your site. Double dig the soil to a minimum depth of 18 to 20 inches. Spread a generous layer of compost, shredded leaves, or other organic matter over the soil. Add an organic fertilizer and other amendments as needed. Turn the soil again, incorporating all the amendments thoroughly. Level the soil surface with a garden rake. Break up any remaining clods. Water to settle the soil, and you're ready for planting.

Space plants according to their growth rate and size at maturity. Plant fast-growing perennials, ornamental grasses, and other herbaceous plants 1 to 3 feet apart, depending on the mature size of the plant. Plant junipers and other large woody plants 3 feet apart. Plant slow-growing woody plants like wintergreen (*Gaultheria procumbens*) 1 foot apart.

Arrange the plants within the bed according to your design. For each plant, dig a hole large enough to accommodate the loosened root ball. If you're using container plants, make sure the plants are positioned at the same level at which they grew in the containers. Soak the roots of bareroot plants for several hours before planting. Remove the plants from the water one at a time and spread the roots evenly over a dome of soil in the bottom of the planting hole. Check the level of the crown to make sure it's at the right planting depth.

Mulch the site after planting to control weeds and reduce moisture loss. Water newly set plants thoroughly. Groundcovers need regular watering until they are well established—an entire growing season for woody plants. Pull weeds early to avoid competition.

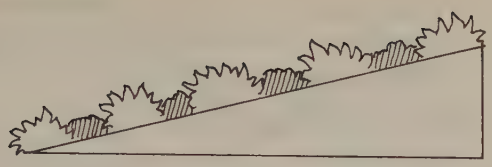
Groundcovers as a group are tough, trouble-free plants. But some pest and disease problems are inevitable in any garden situation. Prevention is the best control. Keep plants healthy, well watered, and mulched. Remove weeds that can harbor pests.

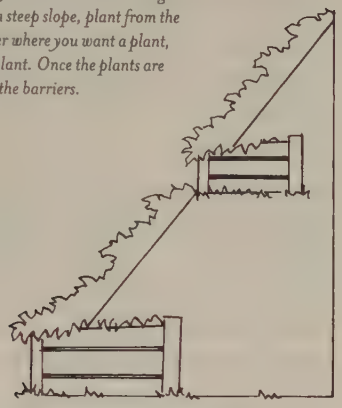
Growing Groundcovers

Groundcovers are a diverse group of plants. Propagation techniques vary according to whether you're dealing with a shrubby, vining, or perennial groundcover. Most groundcovers can be grown from seed started indoors or direct-seeded outdoors. But you'll get quicker results from fast-growing groundcovers if you take cuttings or divide them.

Take cuttings from perennial groundcovers like English ivy (*Hedera helix*), spotted lamium (*Lamium maculatum*), leadwort (*Ceratostigma plumbaginoides*), pachysandra, periwinkle, and sedum in early to midsummer. You can divide groundcovers in spring or fall. If the plant is a vine or creeper like ajuga, creeping phlox (*Phlox stolonifera*), English ivy, Allegheny foamflower, periwinkle, or wintercreeper (*Euonymus fortunei*), sever rooted plantlets from the parent stem. Lift clumps of perennials like astilbe, bergenia (*Bergenia* spp.), blue fescue (*Festuca caesia*), crested iris (*Iris cristata*), daylily, and hosta, and separate the crowns.

A slow but easy method of propagating woody groundcovers like cotoneasters (*Cotoneaster* spp.) and junipers is layering—encouraging branches to root where they touch the ground.





Planting groundcover on a gentle slope. Where the ground slopes gently, you can plant groundcovers directly in the bank, then mulch around them until they're established. Planting groundcovers on a steep slope. On a steep slope, plant from the top down. Put up a wooden barrier where you want a plant, pile soil behind the barrier, and plant. Once the plants are established, remove the barriers.

Beyond the Traditional Lawn

Nothing beats a lawn for playing catch, and a smooth, green swath of lawn sets off flowerbeds perfectly. But too much lawn can be boring to look at and time-consuming to mow. Why not convert some of that grass into a beautiful bed of groundcovers or an island of colorful flowers?

The Best Use for Your Backyard

How much lawn you really need depends on how you use your yard: Parties and picnics? Ball playing and swing sets? Sunbathing and strolling? Once you decide, you can determine exactly how much of the high-maintenance green stuff you need, and how much space you can devote to other, less labor-intensive landscape options. Here's a sampling of your choices:

- Low-maintenance groundcovers with attractive foliage or flowers
- Aromatic herb lawns that are pretty and useful
- Beautiful butterfly garden or meadow
- Tree and shrub borders or island beds for shade and beauty

Get to Know Good Groundcovers

Many groundcovers, such as moss pink (*Phlox subulata*) and mother-of-thyme (*Thymus serpyllum*), tolerate mowing and foot traffic. Flowering groundcovers, such as spotted lamium (*Lamium maculatum*), will add color to your landscape, and berry-bearing groundcovers, such as wintergreen (*Gaultheria procumbens*), will attract wildlife.

When it comes to care-free plantings on tough-to-mow sites, groundcovers are the answer. Review this handy checklist before you buy:

- Match plant choices to your site conditions—sun, shade, water, soil type, heat and cold, and foot traffic, and ask at the nursery for those that have a proven track record in your area.
- Mowing tolerance is important if you'll routinely be mowing around the groundcover area.
- Plants that spread by runners or stolons (underground stems) will fill an area more quickly than clump-forming plants.
- Evergreen groundcovers look good year-round and offer protection from soil erosion.
- When it comes to appearance, choose groundcovers based on leaf texture and color. Flowers are merely a short-term bonus.
- Plants with dense growth habits discourage weeds.

Getting Ready for Groundcovers

Beautiful, thick, weed-smothering areas of groundcover start with thorough soil preparation, especially in difficult sites. Preparing the soil helps get your groundcovers growing quickly and gives them a head start over weeds.

You'll need to remove the sod, then prepare the soil, tilling deeply and adding organic amendments.

Tackle Tough Sites with Terrific Groundcovers

Dry, shady sites, such as the areas under shade trees and shrubs, beneath eaves, and on shaded slopes, are some of the toughest challenges a gardener faces. Constantly wet areas are trouble spots, too. And sunny slopes are awkward to mow. Before you despair of ever having anything grow in these areas, try a groundcover that's partial to those conditions.

5 GREAT GROUNDCOVERS FOR DRY SHADE

Lawn grasses have a hard time growing in shade, especially dry shade. Instead of struggling to maintain a lawn under these conditions, replace it with groundcovers that will thrive.

- Ajuga (*Ajuga reptans*): Green, purple, or variegated leaves with blue, white, or pink flowers; 4 to 6 inches tall. Zones 4 to 8.
- Epimediums (*Epimeduim* spp.): Evergreen or semievergreen, heart-shaped foliage; 6 to 12 inches tall. Zones 3 to 8.
- Wintercreeper (*Euonymus fortunei*): Glossy evergreen leaves; 4 to 6 inches tall; will climb trees. Zones 4 to 8.
- Lilyturfs (*Liriope* spp.): Green, grasslike foliage with purple or white flower spikes; 18 inches tall. Zones 5 to 9.
- Common periwinkle (*Vinca minor*): Trailing, evergreen plant with shiny, dark green foliage and lavender-blue or white flowers; 4 to 6 inches tall. Zones 4 to 9.

Continued →

4 GROUNDCOVERS FOR SOGGY SITES

Even if you get grass to grow in a soggy area, the spot is usually too wet to mow. Instead, fill in the moist spots with groundcovers that enjoy the dampness. The plants below will thrive in moist to wet soil in sun or shade.

- Lady's-mantle (*Alchemilla mollis*): Pale, gray-green foliage that is velvety soft to the touch with sprays of yellow-green flowers; 12 inches tall. Zones 3 to 8.
- Astilbes (*Astilbe* spp.): Fernlike foliage with white, pink, or red flowers; 1 to 4 feet tall, depending on species. Zones 3 to 8.
- Hostas (*Hosta* spp.): Bold and beautiful heart-shaped or lancelike leaves in many sizes and shades of green; many variegated types, with white or lavender flowers in summer; 6 to 48 inches tall, depending on species. Zones 3 to 8.
- Creeping Jenny (*Lysimachia nummularia*): Small rounded leaves with yellow flowers; 2 to 4 inches tall. Zones 3 to 8.

5 SUNNY-SLOPE CONTENDERS

If pushing and pulling a lawn mower up slopes isn't your idea of fun, put a stop to steep-site maintenance with fast-growing plants and a cover of mulch to conserve moisture.

Save Time, Mulch First

Trying to lay mulch between plants in a newly planted expanse of groundcover can be a long, tedious task. You can save yourself some time by laying the mulch first. This is especially helpful when planting groundcover plugs or plants in small pots. After laying the mulch, you can easily plant through it with a trowel without pulling up toomuch soil on top of the clean mulch.

- Maiden pinks (*Dianthus deltoides*): Narrow, blue-green leaves; pink or white flowers; 6 to 12 inches tall. Zones 3 to 9.
- Wintercreeper (*Euonymous fortunei*): Trailing or climbing evergreen plant; many types with variegated leaves; 1 to 2 feet tall. Zones 4 to 9.
- Perennial candytuft (*Iberis sempervirens*): Dark, evergreen leaves; flat, bright white flower clusters in spring; 6 to 12 inches high. Zones 3 to 9.
- Junipers (*Juniperus* spp.): Needle-leaved evergreen available in many forms, from prostate, 6-inch-tall types to large trees. Select a variety that matures to a height that's best for your site. Zones 3 to 9, depending on species.
- Thymes (*Thymus* spp.): Creeping, fragrant-leafed herbs with tiny white or pink flowers; foliage may be variegated; 1 to 12 inches tall. Zones 5 to 9.

5 TOUGH PLANTS FOR SHADY SLOPES

If you have a shady slope, replace the hard-to-mow grass with one of these easy-care, shade lovers.

- Ajuga (*Ajuga reptans*): Green, purple, or variegated leaves with blue, white, or pink flowers; 4 to 6 inches tall. Zones 4 to 8.
- Epimediums (*Epimedium* spp.): Spreading plant with evergreen or semievergreen leaves; small yellow, pink, bronze, or white flowers in early spring; 5 to 12 inches tall. Zones 3 to 8.
- English ivy (*Hedera helix*): Evergreen vine; 6 to 8 inches high when creeping on the ground; will climb trees to 50 feet. Zones 5 to 9.
- Japanese pachysandra (*Pachysandra terminalis*): Glossy green leaves; plant spreads by runners; white flowers; 6 to 9 inches tall. Zones 5 to 9.
- Common periwinkle (*Vinca minor*): Trailing evergreen plant with shiny, dark green leaves and lavender-blue or white flowers; 4 to 6 inches tall. Zones 4 to 9.

Sweetly Scented Herb Lawns

While many people think grass is a must in high-traffic areas, there are other plants that work just as well under fairly heavy foot traffic. Low-growing herbs such as dainty-but-tough thymes and free-ranging mints can make excellent groundcovers. And herbs offer bonuses that grass lacks. Tread on them or nick them with trimmers, and they'll perfume the air for you. Many herbs are also perfect when you're in a pinch for something to season tonight's dinner! Here are some great-smelling choices:

ROMAN CHAMOMILE

(*Chomomelum nobile*)

Forms a soft, dense carpet of fine yellow-green foliage that resembles Irish moss.

- Unlike Irish moss, chamomile is sturdy enough to be walked on.
- Undisturbed, chamomile can reach 9 inches tall, but light foot traffic keeps it low enough to make mowing unnecessary.
- It's a fast spreader—individual plants that are planted 6 inches apart will fill in solidly in a single season.
- The yellow-centered flowers that rise above the mat add an attractive touch.
- It's not a good choice if you're allergic to ragweed, as Roman chamomile and ragweed are related.

SWEET WOODRUFF

(*Galium odorotum*)

A shade lover with a light, sweet fragrance that registers differently with different people—some smell vanilla, others new-mown hay.

- Sweet woodruff is well suited as a groundcover under trees.
- It grows rapidly and covers quickly, continuing to spread by self-seeding once established.
- Its tiny white flowers look delicate, but sweet woodruff is hardy to at least 30°F (Zone 4).

MINTS

(*Mentha* spp.)

Legendary for their invasiveness, but if it's a lawn you want, mints make a tough, dense groundcover.

- Weeds don't stand a chance of competing when up against established mint.
- Grow mint where it can spread at will without causing harm or where it can be easily confined.
- Hardiness varies with variety from subtropical all the way up to Zone 3.
- Corsican mint (*M. requieni*) is tiny and too tender to walk on, but it makes a very tight, low-growing mat only 1 inch or so high that looks great between stepping stones, or as a filler in beds.
- Pennyroyal (*M. pulegium*) makes a good groundcover—either by itself or planted into an existing lawn. It's tough enough for light traffic and is easy to keep low by mowing.
- Peppermint (*M. x piperitum*) mixes nicely with grass. Mowing keeps it low, and the grass helps cushion it from heavy foot traffic. Don't use it to replace grass; it's a complement that has a wonderful scent that makes mowing more pleasant.

7 Reasons to Get Rid of Some Lawn

1. To conserve water
2. To stop mowing
3. To attract beneficial insects so you won't need pesticides
4. To attract butterflies
5. To feed and provide habitat for birds and other wildlife
6. To use your yard to restore native plants
7. To increase your home's energy efficiency

THYME

(*Thymus* spp.)

Not just for the kitchen anymore. Creeping woolly thyme is a good groundcover choice, but other creeping varieties are also available.

- Creeping varieties grow low and spread quickly.
- Thymes sport colors ranging from light lemon yellow to deep grayish green.
- Originally native to dry regions, most thymes grow well in dry, poor soil, and they actually require such hardships to develop their best flavor.
- Many thymes are hardy down to -30° to -40°F.

Enjoy the Beauty of a Wildflower Meadow

Creating a meadow, as more and more people are discovering, is a way to make part of your lawn area more inviting to birds, butterflies, and other wildlife. Each part of the country has native wildflowers that are favorites of the birds of that region. Wherever you live, a wildflower meadow will provide food and cover for all sorts of birds and butterflies, such as goldfinches, hummingbirds, indigo buntings, and monarch butterflies.

START SMALL

If you're considering planting a meadow garden, the best advice is to start small. Removing sod to prepare the site for a new planting involves a bit of work, so you won't want to dig up your entire yard at once. Select a section of your backyard where you'll have the opportunity to observe the planting through all the seasons before you make over your entire lawn.

THINK BIG

Keep in mind that a meadow looks distinctly different from a closely cropped lawn. Whether you choose groundcovers or a mix of native grasses and wildflowers, the look will be more tufted and will change through the seasons. Some native prairie or meadow plants can even grow as tall as 4 to 8 feet!

What you decide to plant is based on what you want and where you live. For example, if you live in the Midwest, you could instill a prairie planting. But if you're in the Southwest, the environment is too dry and hot for those plants; a more appropriate choice would be desert groundcovers or a blend of native grasses and groundcovers.

Don't skimp when it comes to selecting plants and buying seed. Your meadow will be a thing of beauty for years to come, so you won't want to waste time or money on plants that won't thrive. If your budget is tight, increase the percentage of grasses. They're a little less costly than some of the native prairie flowers. Besides, grasses form the backbone of the meadow.

6 STEPS TO A GREAT MEADOW

1. **Prepare the soil.** First you'll need to remove the grass or whatever is growing in the area where you want a meadow. Mow the grass low, and then turn under any remaining vegetation with a rotary tiller, which can be rough going, or rent a sod cutter to remove the sod completely. Then till the soil and add organic amendments.
2. **Plant.** The best time to plant in Zone 3 and warmer is about one month before the first killing frost in fall. In colder zones, plant as soon as the soil can be worked in spring.

   Broadcast the seed, walk on it to press it into the soil, and cover with straw to keep the soil from drying out. As an alternative, you can set transplants in the soil, rather than starting from seed.
3. **Water.** Keep seedlings or transplants moist until they're established—about four to six weeks.
4. **Mulch.** When the seedlings are large enough to identify as flowers and not weeds, apply 3 to 4 inches of organic mulch.
5. **Weed.** Walk through the meadow occasionally during the first year and pull out unwanted plants.
6. **Mow.** Starting the year after planting, your meadow will need to be mowed once a year in early spring. Use a string trimmer or scythe and cut 4 to 6 inches above the ground so you won't disturb the plant crowns. You can hire someone with the proper equipment to mow large meadow areas.

Calculate Your Coverage

When planting groundcovers, you can choose just one or use a combination. If you use a mixture, it's best to group each type separately rather than mixing them together. In general, space plants 6 to 10 inches apart (measuring from their centers) in staggered rows.

To get quicker and more uniform coverage, buy plants in 4-inch or bigger pots, and pull apart the individual plantlets in each pot. Plant the pieces a little more closely, and the sections will fill in the spaces quickly.

To determine how many plants you'll need, multiply the number of square feet of the area to be covered by the number of plants you plan to use per square foot. For instance, if you want to use 3 plants per square foot and the groundcover garden area is 6 feet square, you'll need 18 plants.

Liven Up Grassy Areas with Colorful Bulbs

Spring bulbs are often our first sign of spring—they can sprout even before the first robins show up! But bulbs aren't just for flowerbeds. They look great naturalized in grassy areas, too. Each spring they can give your lawn a colorful meadow look, then when mowing begins, you'll never know they were there.

Small bulbs are best for naturalizing—they're easier to plant and they bloom reliably year after year. You can even plant them under deciduous trees, because they'll be up and blooming before the trees leaf out and create their summer shade. Here are some to try:

- Grecian windflower (*Aneomone blanda*)
- Crocuses (*Crocus* spp.)
- Common snowdrops (*Glanthus nivalis*)
- Summer snowflake (*Leucojum aestivum*)
- Grape hyacinth (*Muscari armeniacum*)
- Daffodils (*Narcissus hybrids*)
- Siberian squill (*Scilla sibirica*)

To create a carpet of springtime bloom in an existing lawn, simply make a hole in the grass with a narrow trowel, dandelion digger, or garden knife. For small bulbs, you can just wiggle your tool back and forth to create a small hole and slip the bulb in place. For larger bulbs, you may have to actually lift the sod and soil, insert the bulb, and put the flap of turf back in place.

If you have a lot of large bulbs to place, use a spade or shovel and remove larger areas of turf—about 1 foot square. Loosen the soil, plant the bulbs, replace the turf and water.

Creating Islands of Beauty

Another way to cut back on lawn care while increasing the value and enjoyment you get from your landscape is to start with existing features, like a tree or shrub in your lawn, or a fence along the edge of your lawn, and create a garden around the feature.

DEALING WITH TREE ROOTS

Instead of struggling to grow and mow grass under trees, plant shade-tolerant shrubs and groundcovers under trees, then mulch for a low-maintenance planting you'll enjoy for years to come. If you have shallow-rooted trees such as maples and beeches, there will be lots of fibrous roots to work around. Deep-rooted trees such as oaks have more root-free places to plant. Whichever type of tree you have, take care not to damage large roots, and don't remove more than 5 percent of smaller roots while planting.

Add just enough compost to fill your holes and bring new plants up to the original soil level. Never bury the crown of a tree or it will decline; oaks and sugar maples are particularly vulnerable.

WHEN ALL ELSE FAILS, MULCH

Some shady areas defy gardening attempts, and that's when mulch makes the easiest groundcover of all. A layer of bark mulch can give you a care-free, weed-free surface instantly; it's especially good for unsociable sites like under black walnut trees or the heavy shade of southern magnolias. Spread mulch all the way out to the drip line for easier mowing, no weeding, and happy trees.

MOWING STRIPS EASE MAINTENANCE

Use edging strips around island beds to keep lawn grass from overtaking your islands. You can mow around them with a single pass and won't have to trim by hand. To install a brick mowing strip, use a sharp spade to dig a brick-size trench around your bed. Starting at one end of the trench, lay the bricks in side-to-side, butting them snugly against each other and leveling them as you go. Backfill as necessary and sweep dry soil into the spaces between the bricks.

Got a Fence? Eliminate the Hassles

Plantings of trees, shrubs, groundcovers, and easy-care perennials can eliminate tedious weeding or trimming along a fence. Select plants suited to the site, then plant and mulch. No more snagging the mower on the fence or coming back later with a trimmer.

If you need to be able to paint your fence occasionally or need access to plants from the back, leave a 2-foot-wide, mulched maintenance path between the fence and the plants.

Tips for Meadow Success

Set the stage for success by choosing the right kind of meadow plants.

- **Choose a regional mix.** Most seed companies and nurseries offer both wildflower mixes that are designed for specific parts of the country.
- **Avoid "instant meadow" mixes.** They are mostly annual flowers or inexpensive generic wildflowers.
- **Save on weeding with aggressive wildflowers.** A mix of vigorous wildflowers won't give you the variety a more carefully planned and developed meadow will provide, but it will get you a flower-filled meadow fast. Try perennials like common yarrow, Queen-Anne's-lace, dame's rocket, oxeye daisy, and evening primrose. In two to three years, they'll take over and choke out any other plants with very little help from you.

Ornamental Grasses

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

It's time to get to know the grasses you cut only once a year: the ornamental ones. They don't need supplemental watering once established, the more vigorous types can hold their own against weeds, and they're rarely troubled by diseases or insects. Best of all, ornamental grasses are truly plants for all seasons. In autumn, many dry to beautiful shades of tan and ochre. Others are evergreen or semi-evergreen.

Some ornamental grasses quickly grow to the size of large shrubs, making them great choices for quick landscape effect. Yet as vigorous as they are, the best of them don't need dividing. And no pruning headaches—just cut them down to the ground once a year in early spring.

With Grasses, It Pays to Know When They Grow

Most ornamental grasses will grow nearly anywhere, but knowing a little about their likes and dislikes will help you select the best ones for your site and situation. For gardeners, grasses fall into two general groups, as determined by their season of active growth: Warm-season grasses grow during the summer; cool-season ones during cooler months.

Although both groups include great low-maintenance plants, warm-season grasses require even less work to grow than cool-season ones. Here are some general characteristics of each group to keep in mind as you select grasses for your landscape.

WARM-SEASON GRASSES

Late spring and summer are the main growing seasons for warm-season grasses. They bloom from June through September, depending on the species. In winter, their foliage

Continued →

turns attractive shades of buff and tan. Generally, they are more tolerant of clay soils and poor drainage and rarely need dividing. Once a year in early spring, they need to be cut to within a few inches of the ground.

COOL-SEASON GRASSES

These grow actively during the cool seasons of the year—primarily spring and fall, winter in mild areas. Their foliage is often evergreen or semi-evergreen, and they bloom in spring or early summer. As a result, they provide landscape interest when warm-season grasses are least effective. Cool-season grasses are fussier about soil, though. In general, they need better drainage and are less tolerant of heavy clay than warm-season grasses.

Cool-season grasses generally aren't cut back completely in early spring, as warm-season ones are. Instead, they need more selective trimming and cleaning up at winter's end. Because they tend to die out in the center of the clump, they need dividing every two or three years.

Corralling Aggressive Spreaders

Keep bamboos and ornamental grasses that spread aggressively under control by planting them inside a concrete culvert, a large garbage can with the bottom cut out, or another type of "container." The container should extend to a depth of 2 to 3 feet. Leave a 2-inch rim above the soil to control wandering aboveground stems.

Dividing Grasses Large and Small

The good news about dividing ornamental grasses is you may never need to do it. Cool-season grasses need dividing every two to three years, as new growth begins to appear in fall, winter, or early spring. Warm-season grasses almost never need dividing, but if you want more plants or need to improve the spacing in an overcrowded planting, tackle the project after you've given them their annual haircut in spring.

Get-tough division for large grasses. You'll need to use an ax, or a wedge and a small sledgehammer, to divide large warm-season grasses. Cut the crown into several hunks, then pry the hunks out with a shovel and transplant them. If you only need a division or two, pry them off the side of the clump.

Dividing large clumps of ornamental grasses isn't a job for the faint-hearted. The easiest way to tackle the task is to do it right in the ground. If you want to separate the clump into small divisions with three to five growing points each, however, you'll need to dig out the clump and wash off the soil so you can see what you're doing. Although it's more time-consuming, you won't believe how many grass plants you can get from a clump this way.

Simple division for smaller grasses. Dividing cool-season grasses and small clumps of warm-season ones is relatively easy. Use a spade to lift small clumps of grasses from the soil, then rinse the roots clean with a hose. Slice away dead areas and divide the actively growing sections with a sturdy knife or a spade. Then replant or pot up the divisions.

Grasses as Groundcovers

Grasses with spreading habits are generally too invasive for a perennial garden, but they make excellent groundcovers. Grow them alone or combine them in beds with other aggressive groundcovers. It's best to plan a site that will help you keep them in bounds without extra work. Regular mowing around a planting of them will help as well. For example, groundcover grasses are perfect for island beds surrounded by lawn, or sites with lawn on one side and a road or pond on the other. Or plant them in containers sunk in the soil.

You can also use clump-forming grasses as groundcovers; just plant them on even centers as you would a vegetable garden that's been planted intensively. On shady sites, try this technique with the grasslike sedges (*Carex* spp.) and woodrushes (*Luzula* spp.). On sunny ones, try quaking grass (Briza media), fescues (*Festuca cultivars*), tufted hairgrass (*Deschampsia caespitosa*), blue oat grass (*Helictotrichon sempervirens*), and fountain grass (*Pennisetum alopecuroides*).

Basic Grass Care for Bountiful Results

Ornamental grasses have a plant-it-and-forget-it quality that ensures them a place in the heart of every gardener. Once you've chosen grasses suited to your site conditions and landscape, planting and care are simple matters. Soil preparation is largely unnecessary, particularly if you stick with the warm-season grasses. Except for requiring full sun, these grasses really don't care where you put them. Below, you'll find what little you need to know to grow a landscape full of lush, healthy, low-maintenance ornamental grasses.

PLANTING GRASSES

About the only thing you need to do to prepare an area for grasses is remove any existing vegetation and plant. Since most ornamental grasses don't ever need to be divided, planting them properly the first time really pays off. You can plant containerized grasses any time from spring through fall, but you'll minimize watering chores if you plant early or late enough for your new grass to catch spring or fall rains.

Dig your grasses a good home. Plant your grasses in holes that are about twice as wide as the containers. Spread a mixture of soil and compost in the hole, then settle the plant so its crown is about 1 to 2 inches above the soil line. Refill the hole with soil and compost, and water thoroughly to settle the plant in place.

Planting pot-grown grasses. After removing an ornamental grass from its pot, use a knife to score the roots around the outside of the root ball. Or tease them out with a screwdriver. This encourages the roots to branch and spread out in all directions.

Ornamental Grasses for Special Sites

To find the best ornamental grasses for your garden, look through the list below. (You'll find true grasses and related grasslike plants listed.) For each, you'll find the season of growth, height, hardiness, and suggestions for special uses. Grasses grow well in full sun with average to rich well-drained soil, but many grasses can also grow well in problem sites — like heavy clay soil. Ornamental grasses make great additions to low-maintenance landscapes since they're so easy to care for, and because they'll grow in sites where other plants might need special pampering or special advance soil preparation in order to thrive.

Name	Description	Special Uses
Andropogon gerardii (big bluestem)	Warm-season grass. Blue-green to silvery foliage; purplish flower spikes. Height: 4–7+ feet. Zone 4.	Clump-forming habit. Will grow in heavy clay soil; tolerates drought.
Bouteloua spp. (grammagrass)	Warm-season grasses. Gray-green, fine-textured foliage; interesting, one-sided flower heads. Height: 1–2 feet. Zone 4.	Clump-forming habit. Withstand mowing. Will grow in heavy clay or sandy soil; withstand drought.
Briza media (quaking grass)	Cool-season grass. Evergreen foliage with attractive seed heads. Height: 1–1½ feet. Zone 4.	Clump-forming habit. Will tolerate a wide range of soils provided it has moisture.
Calamagrotis arundinacea 'Karl Foerster' (Foerster's feather reed grass)	Cool-season grass. Arching foliage with tall, brown to golden flower spikes; evergreen in mild climates. Height: 2–4 feet. Zone 5.	Clump-forming habit. Will grow in heavy clay soil and poorly drained or wet sites.
Carex spp. and cultivars (sedges)	Cool-season growers. Fine-textured, arching foliage in blue, green, silvery, or variegated; many are evergreen. Height: 6 inches–3 feet. Many species hardy to Zone 5.	Clump-forming habit. Will grow in shade, heavy clay soil, and poorly drained or wet sites. *C. morrowii* (Japanese sedge) and *C. sylvatica* (forest sedge) withstand drought.
Chasmanthium latifolium (Northern sea oats)	Warm-season grass. Bamboolike foliage with attractive seed heads. Height: 2–3 feet. Zone 5.	Clump-forming habit. Will grow in shade, sandy soil, and poorly drained or wet sites; withstands drought.
Erianthus ravennae (Ravenna grass)	Warm-season grass. Gray-green foliage with silvery flowers. Height: Foliage 4–5 feet; flowers 8–12 feet. Zone 6.	Clump-forming habit. Will grow in poorly drained or wet sites; withstands drought.
Festuca cinerea (blue fescue)	Cool-season grass. (Formerly F. ovinia 'Glauca.') Blue-green foliage; evergreen. Height: 8–18 inches. Most to Zone 4.	Clump-forming habit. Will grow in sandy, well-drained soil; withstands drought.
Glyceria maxima 'Variegata' (variegated manna grass)	Warm-season grass. Foliage striped creamy yellow. Height: 2–3 feet. Zone 5.	Vigorous spreading habit. Will grow in poorly drained or wet sites.
Helictotrichon semperfirens (blue oat grass)	Cool-season grass. Blue-green foliage; evergreen. Height: 12–18 inches. Zone 4.	Clump-forming habit. Will grow in sandy soil; withstands drought.
Juncus spp. (rushes)	Cool-season growers. Semi-evergreen foliage; many have attractive seed heads. Height: 1–4 feet, depending on species. Some to Zone 4.	Clump-forming habit. Will grow in poorly drained or wet sites.
Luzula sylvatica (greater woodrush)	Cool-season grower. Mounds of matlike evergreen foliage. Height: 8–12 inches. Zone 4.	Clump-forming habit. Will grow in shade, heavy clay soil, and poorly drained or wet sites.
Miscanthus sinensis (maiden grass)	Warm-season grass. Dense clumps of arching foliage; attractice seed heads. Height: 5–6 feet. Zone 5.	Clump-forming habit. Will grow in heavy clay soil and poorly drained or wet sites; 'Gracillimus' withstands drought.
Panicum virgatum (switch grass)	Warm-season grass. Green to gray-green foliage; showy seed heads. Height: 4–7 feet. Zone 5.	Clump forming habit. Will grow in heavy clay soil and poorly drained or wet sites; withstands drought.
Pennisetum alopecuroides (fountain grass)	Warm-season grass. Mounds of arching foliage; showy seed heads. Height: 2–3 feet. Zone 6.	Clump-forming habit. Will grow in heavy clay soil; withstands drought.
Phalaris arundinacea var. *picta* (white-striped ribbon grass)	Warm-season grass. Foliage striped with green and white. Height: 2–3 feet. Zone 4.	Spreading habit. Will grow in heavy clay soil and poorly drained or wet sites; withstands drought.
Schizachyrium scoparium (little bluestem)	Warm-season grass. Light green foliage topped by fluffy seed heads. Height: 2–3 feet. Zone 3.	Clump-forming habit. Will grow in sandy soil; withstands drought. 'Blaze' has especially vibrant fall color.
Sorghastrum nutans (Indian grass)	Warm-season grass. Medium green foliage with attractive seed heads. Height: 2–3 feet. Zone 4.	Clump-forming habit. Will grow in heavy clay or sandy soil and poorly drained or wet sites.
Spartina pectinata 'Aureomarginata' (golden-edged prairie cord grass)	Warm-season grass. Green foliage edged in yellow. Height: 3–6 feet. Zone 4	Spreading habit; can be invasive in moist soil. Will grow in heavy clay soil and poorly drained or wet sites.
Sporobolus heterolepis (prairie dropseed)	Warm-season grass. Fine-textured foliage; attractive seed heads. Height: 2–3 feet. Zone 3.	Clump-forming habit. Will grow in sandy soil; withstands drought.

Fern Affairs

Roger Yepsen

If you're considering what to do with a shady area of the yard, give the hostas and pachysandra a rest and investigate the many shapes and textures and personalities to be found among ferns. That's not to say they make a visual splash. Ferns mostly come in shades of green, and these so-called primitive plants don't produce flowers. Still, once you begin noticing ferns, their individual personalities can be very charming. For a quick introduction to these plants, here are three very different forms.

- The ostrich fern (*Matteuccia struthiopteris*) is an eager grower, quickly reaching 4 to 6 feet, and it looks like what you'd expect of a fern. It will succeed in either sunny or shady spots if the soil is moist.
- The dainty Japanese painted fern (*Athyrium nipponicum*) is shaped like a fern, but its coloration is mildly outrageous. The stems are deep red, and the leaves are frosted with silver. To bring out the best color, place them in light shade with perhaps some morning sun. They also tend to be brighter in areas with cooler summer temperatures.
- The maidenhair fern (*Adiantum raddianuma*) is conventional ferny green (except for the contrasting black stems), but its form is strikingly different. The delicate fronds are low-growing fans, making this species a good choice for the front of beds and for easing the edges of a shady path. Maidenhairs do best under bright filtered light rather than in deep shade.

Install a Stumpery

Most yards have at least one unloved and all but unredeemable spot, where low light, so-so soil, and inaccessibility seem like unsolvable issues. These odd nooks are candidates for a stumpery, a modest-size landscape feature arranged around one or more stumps for a woodsy, picturesque effect.

Farmers and contractors routinely yank stumps of felled trees from the ground when clearing land, and you may be able to pick them up for no charge. If you can't find stumps, sections of log will do. Either way, you'll have a centerpiece around which to grow ferns and woodland plants, just as Victorian gardeners did during the stumpery fad (yes, there really was one) of more than a hundred years ago.

To make the stumps or logs look as though they've been moldering for decades, use a blender to process moss, yogurt, and water into a slurry, then spread it on these objects. If there's room enough, install a rustic bench on which to contemplate your romantic woodland niche.

Handling bareroot grasses. If you've ordered bareroot grasses from a mail-order nursery, unpack and inspect them as soon as they arrive from the nursery. Each plant should have at least two or three culms (growing points). Do not accept plants consisting of a single culm; they have a high failure rate. The root system should look husky. Scratch the skin of a root with your fingernail; the tissue beneath should appear whitish, not brown or black. Blackened tissue means the roots are dead. If anything looks bad, notify the nursery immediately. Cool-season grasses, especially, are prone to arrive in poor condition.

Plant bareroot grasses immediately. If you can't plant right away, settle them temporarily in containers of potting soil, water thoroughly, and keep them in a shady place. When you plant them permanently, dig a hole wide and deep enough to accommodate the roots. Fan out the roots over a cone of soil, and plant them so the crown is about an inch below the soil surface. After planting, water thoroughly and mulch.

CARING FOR YOUR GRASSES

Once they're established, your grasses will thrive almost in spite of you. Except for the first couple of months after planting or during prolonged drought, they will do fine without any additional water.

Fertilizing is entirely optional. If you're feeling extravagant, give your grasses a spring feeding with a high-nitrogen fertilizer, such as blood meal, or anything you would use on your lawn. Apply the fertilizer around the clump, not on top of it, and water it in thoroughly.

The only other care your grasses need is their once-yearly trimming. Cool-season grasses are evergreen and don't need a dramatic spring cleanup like warm-season grasses. Just clean them up each spring by cutting off browned foliage. Give warm-season grasses a spring crew cut to clear the way for new growth and get the most landscape interest from your grasses.

Give 'Em Room to Grow

Grasses form big clumps, and one of the most common mistakes is planting them too close together. When planting warm-season grasses, be sure to pick a site large enough to accommodate their size at maturity. That way, you'll only need to divide them if you want more plants for another part of your landscape. Here's a useful rule of thumb: Allow as much space between grasses as their mature height. For example, leave 5 feet of space between a grass that grows 5 feet tall and its neighbors.

Another common mistake is to plant clumps of grasses as individual specimens in the lawn. Not only does this create a spotty-looking design, it also creates more obstacles to mow around. To simplify your mowing and get more visual impact from your grasses, group them together or combine them with perennials or shrubs. When combining grasses with other plants, remember the rule of thumb about spacing. Resist the temptation to crowd other plants around them; you'll only have to move them in a year or two.

Bamboos Are Low-Maintenance Grasses, Too

Bamboos are among the most versatile, beautiful, and low-maintenance plants in the grass family. They are pest- and disease-free, too. Their only drawback—one that can be used to advantage in some situations—is that many of them are aggressive spreaders. Keep them in bounds by planting them inside an underground barrier. Or select a site with natural barriers. For example, use bamboo as an erosion-controlling ground cover on a slope between a pond and a lawn, or between a lawn and a road. Mowing will control bamboo shoots on the lawn side. Another simple solution is to plant bamboo as a specimen in your lawn and just contain it by mowing around it. But watch out if there is an unmowed zone beyond the lawn; bamboo stolons can travel 20 to 30 feet.

Following is a list of recommended spreading bamboos.

Black bamboo (*Phyllostachys nigra*): 25 feet tall; Zone 6, Zone 5 in sheltered location.

Dwarf green-stripe bamboo (*Pleioblastus viridi-striatus*): 2 feet tall; Zone 5.

Dwarf white-stripe bamboo (*Pleioblastus variegatus*): 1–2 feet tall; Zone 5.

Kuma bamboo (*Sasa veitchii*): Plant in shade; 3 feet tall; Zone 5.

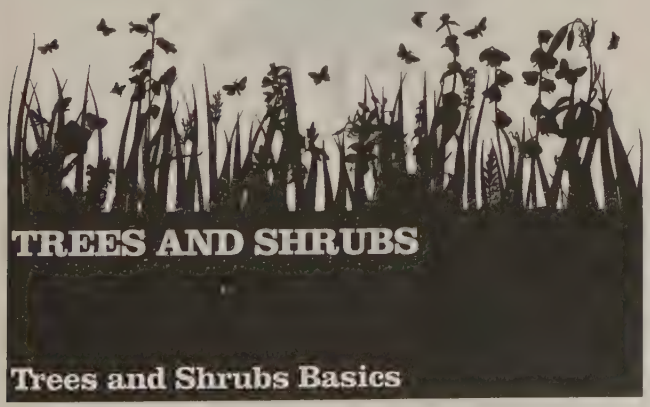
Pygmy bamboo (*Arundinaria pygmaea*): Excellent low ground cover; Zone 5.

Yellow-groove bamboo (*Phyllostachys aureosulcata*): 25 feet tall; Zone 5.

Or choose a nonspreading bamboo, especially cultivars of the clump-forming fargesias (*Fargesia* spp.), which are evergreen and hardy to Zone 5.

Grow a Grass Windbreak

For quick shelter on the windy side of a perennial planting, ornamental grasses are an easy answer. A row of clump-forming grasses like maiden grass (*Miscanthus sinensis*) behind a perennial planting will shield your perennials from wind and look great, too.



Jeff Cox

Trees, shrubs, and vines form the foundation, framework, and walls of a landscape. They can focus our attention on lovely views or shut out ugly ones. Trees also help to modify the microclimate in our yards by casting shade or serving as a windbreak. They can act as barriers to block the noise and commotion of street traffic.

While trees and shrubs can be expensive, they are true investments that can raise the value of your property. Before you spend money buying trees and shrubs, though, spend time learning about the best plant choices for your site and about how to care for the plants you select. Consult books, local gardening organizations, and county extension agents. Find a reliable nursery, and ask the owner or manager for advice. And for a dose of inspiration, visit public gardens and arboretums.

In this section, you'll find advice on selecting and caring for trees and shrubs, as well as how to use trees, shrubs, and vines for best effect in the home landscape.

Types of Trees and Shrubs

Trees are woody perennials, usually with a single trunk, ranging in height at maturity from 15 feet to giants exceeding 100 feet. A plant thought of as a tree in some parts of the country may be considered a shrub in others. Crape myrtle (*Lagerstroemia indica*) exceeds 15 feet in the South, where it is grown as a small flowering tree, but in the mid-Atlantic area, it may die back to the ground after cold winters and only reach shrub height.

Some of the most familiar and beautiful plants around our homes are shrubs. The graceful sweep of forsythia and the stately form of a privet hedge show the diversity of these woody perennials. Shrubs have multiple stems and range in height from a few inches to approximately 15 feet at maturity, although individual shrubs may grow as high as 30 feet. A shrub trained to a single stem, called a standard, resembles a miniature tree. Here's a look at the types of trees and shrubs most commonly found in home landscapes.

Deciduous trees: These drop all of their leaves at the end of the growing season and grow new leaves the following spring. They are good choices for fall color. Once they drop their leaves, with the exception of some limited root growth, they generally are dormant for the entire winter.

Evergreen trees and shrubs: These hold most of their leaves year-round. Although many people think "Christmas tree" at the mention of evergreens, all plants that retain their green color throughout the year can properly be called evergreens, and there is a broad range of shapes and sizes. Evergreen can mean a 60-foot fir tree—or the diminutive rug junipers used as groundcovers.

Evergreens are divided into two groups according to the general shape of their leaves. Narrow-leaved or needle evergreens include plants such as junipers, pines, and yews. Most needle evergreens are very hardy and can be successfully grown over much of the United States. Some of these, like pines and spruces, are also known as conifers because they bear cones. But not all coniferous trees are evergreen: Larches (*Larix* spp.) and bald cypress (*Taxodium distichum*) are deciduous conifers.

Continued →

Broad-leaved evergreens usually have showy flowers or fruit, and are generally not as cold-hardy as other evergreens. But some types, such as azaleas and rhododendrons (*Rhododendron* spp.), hollies (*flex* pp.), and Japanese barberry (*Berberis thunbergii*) are widely adaptable. Tender evergreens, such as gardenias (*Gardenia* spp.), are grown only in the warmest regions of the country. Broad-leaf evergreen trees include southern magnolia (*Magnolia grandiflora*) and live oak (*Quercus virginiana*).

If you live in a warm area, you may be able to select a third type of "evergreen" tree. Palms are categorized as evergreens, although they are monocots, not dicots like other trees. A dicot forms annual growth rings that increase the trunk's diameter, and their crown is formed of branches. Palms don't form annual growth rings, and they generally don't branch, either—their crowns are made up entirely of their large leaves.

Semi-evergreen trees and shrubs: These keep at least part of their leaves well into the winter. Shrubs such as glossy abelia (*Abelia x grandiflora*) are evergreen in the South and semi-evergreen farther north. And certain cultivars of Chinese or lacebark elm (*Ulmus parvifolia*) keep many of their leaves well into the winter. They may be fully evergreen in the South.

Selecting Trees and Shrubs

Your trees and shrubs will be a part of your life for a long time. Choose them with care. Think about what you want from a tree or shrub. In a design sense, trees and shrubs have a variety of uses. They can be used to screen and filter views, soften hard edges, enclose spaces, and visually connect buildings to the ground. In a good design, they also create an atmosphere that is comforting and restful.

Landscape plants provide visual interest, a catchall term that not only refers to flowers, fruit, fall foliage, and bark, but also to the interesting patterns, textures, and contrasts they create. And a cherished plant that might have been part of childhood, or reminiscent of a favorite place or time, is a soul-satisfying presence.

Trees, shrubs, and other vegetation soak up noise and glare, filter atmospheric impurities, and offer shelter from winds. They also invite wildlife and bring coolness by casting shade, by transpiration, and by wind channeling. These benefits should offer inspiration to gardeners to plan and plant their home landscapes with loving attention and to give them the best possible year-round care.

Before you head to the nursery or garden center to buy shrubs, make a list of desired features. What should your trees and shrubs do—form a windscreen, complete your foundation planting, shade your house, serve as an accent for a flower garden, provide food for wildlife, or serve as a specimen? Would you rather have a display of flowers in spring, brightly colored leaves in fall, showy bark, or persistent fruit in the winter? How big can the shrub or tree get, how often will you have time to prune it, and what showy features do you want? Here are some suggestions for ways to use trees and shrubs in your landscape:

- Use groups of trees and shrubs to block unwanted views or accent desirable ones, both on and off your property, and to give privacy. Evergreens provide year-round concealment. Privet (*Ligustrum* spp.) is a classic hedge plant, but many others also make good hedges. A low-growing hedge, such as common boxwood (*Buxus sempervirens*), can direct traffic around walkways and define borders of

Words to Know

Clump: A tree grown with several closely growing trunks. Birches are often sold as clumps.

Vase-shaped: A tree with upswept branches, narrower in silhouette near the base than at the top, such as American elm.

Globe-shaped: A tree with a rounded, usually low-growing silhouette, such as crab apple.

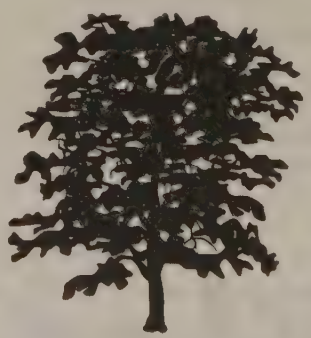
Oval: A tree with branches that form an oval silhouette, such as 'Bradford' flowering pear.

Columnar: A tall, somewhat narrow form, such as 'Columnare' Norway maple.

Pyramidal: A cone-shaped tree, such as spruces or American arborvitae.

Conical: Cone-shaped, but with a narrower profile than a pyramidal tree, such as 'Wichita Blue' juniper.

Weeping: A tree with branches that droop toward the ground, such as a weeping willow.



flower and herb beds. Plant larger shrubs, such as spireas (*Spiraea* spp.) and viburnums, singly or in groups. They can frame outdoor spaces, provide privacy, hide unsightly views, and buffer against wind and noise.

- A unified group of trees and shrubs in a single bed looks better than a widely separated planting, and the arrangement helps protect the trees from lawn mower nicks and gouges.
- Specimen or accent plants are used alone to call attention to an attractive feature such as the finely cut leaves of full-moon maple (*Acer faponicum*), or the showy flowers of saucer magnolia (*Magnolia x soulangiana*). Unusually textured bark, bright fall color, or an interesting shape are other good reasons to showcase a tree or shrub as a specimen plant.
- Use ground-covering shrubs, such as rockspray cotoneaster (*Cotoneaster horizontalis*) or shore juniper (*Juniperus conferta*), to control erosion and ease maintenance on steep banks.
- Low-growing Japanese hollies (*flex crenata*) or abelias (*Abelia* spp.) make good foreground plants for foundation plantings. Medium and tall shrubs, such as yews (*Taxus* spp.) and Chinese junipers (*Juniperus chinensis*), serve as background plants for foundation plantings, as well as for perennial beds.
- Be sure to learn the mature height and spread of the foundation plants you are considering. The rule is patience: Allow time for your new small plants to mature and fill the space you have planned. If you make the mistake of planting cute little arborvitaes (*Thuja* spp.) under the window, or a white pine close to the house, you'll be continually pruning or cutting them down when they outgrow their space.
- Many medium and tall-growing shrubs have naturally occurring or cultivated forms that are smaller and slower-growing. These dwarf and miniature forms, such as dwarf nandina (*Nandina domestica* 'Nana') and dwarf mugo pine (*Pinus mugo* var. *mugo*), generally do not grow more than 3 feet tall. Use them when your planting site is small, or when you want less pruning maintenance.
- Trees supply food, shelter, and nesting sites for birds and other wildlife. Those with berries or other fruits are especially welcome.
- You may want to add trees and shrubs to your landscape that will provide food for you, not just for wildlife and birds. Many common fruit trees, such as apples, pears, peaches, and plums, are available in dwarf sizes that fit neatly into a small corner or even a large container. See Chapter 4 for more on growing fruit.
- For fleshy fruit to be eaten fresh or cooked, try pawpaw (*Asimina triloba*), common persimmon (*Diospyros virginiana*), and Japanese persimmon (*D. kaki*).
- For small, fleshy fruits for jams and jellies, try blueberries, cornelian cherry (*Cornus mas*), crab apples (*Malus* spp.), and wild cherries and plums (*Prunus* spp.).
- For nuts, try hickories (*Carya* spp.), walnuts and butternuts (*Juglans* spp.), pecans (*Carya illinoinensis*), filberts (*Corylus* spp.), and chestnuts (*Castanea* spp.).
- For beekeepers interested in a new taste to their honey, try sourwood (*Oxydendrum arboreum*), lindens (*Tilia* spp.), and water tupelo (*Nyssa aquatica*).

Be realistic about the amount of maintenance you're willing to do. Do you want to plant trees and forget them, or do you enjoy pruning and raking up baskets of leaves on a brisk fall day? For some gardeners, the beauty of the tree or the bounty of the crop outweighs the extra work.

Matching Plant to Site

Consider the characteristics of your site before you head for the nursery. For healthy, vigorous trees and shrubs, match the cultural requirements of the plants you buy to the conditions of your site. While most nurseries stock plants that are hardy in their area, borderline-hardy plants are sometimes offered with no warnings. It's always a good idea to ask. Remember to check catalogs for hardiness information.

Know your soil—its pH, fertility, and consistency. Take a close look at drainage; choose another site if you see standing water at any season. Check the amount of light the plant will receive.

If you're planting trees, be sure to scout out overhead wires, nearby walkways, or other limiting factors. Think about the size of your tree or shrub in 5, 10, or 20 years.

Also remember that as a tree grows, so does the area of ground that it shades. Some trees, such as thornless honey locust (*Gleditsia triacanthos* var. *inermis*), produce only light or filtered shade; grass and other plants generally have enough light to grow under or in the shade of these trees. Other trees, like the sugar and Norway maples (*Acer saccharum* and *A. platanoides*), produce very dense shade in which even shade-tolerant grasses have trouble growing. You'll need to use shade lovers such as ivy, hostas, or ferns—or a mulch—to cover the ground beneath such trees.

Even shade-tolerant plants may have difficulty growing under or near a tree, particularly a large one. If the crown of the tree is dense, as with maples, most rain is shed off the canopy of the tree. The ground immediately below may be dry even after a rain and tree roots absorb much of the available water.

Make a second list of the conditions of your site—soil, water, and exposure. For healthy, vigorous shrubs, match the plant to the site. Combine your two lists to discover the shrubs that best fill your needs.

With your list in hand, you're ready to buy. Remember that shrubs are a long-term investment. It's well worth your time and

Continued ➔

money to seek out and buy good-quality shrubs. Don't base your selection on price alone.

Growing Hedges

Plant a hedge for a privacy screen to block out unwelcome views or traffic noise or to add a green background to set off other plantings. Hedges also provide excellent wind protection for house or garden. Thick, tall, or thorny hedges make inexpensive and forbidding barriers to keep out animals—or to keep them in.

A formal hedge is an elegant, carefully trimmed row of trees or shrubs. It requires exacting and frequent pruning to keep plants straight and level. The best plants for formal hedges are fine leaved and slow growing—and tough enough to take frequent shearing. An informal hedge requires only selective pruning and has a more natural look. A wide variety of plants can be used, many of which have attractive flowers or berries.

PLANTING AND PRUNING HEDGES

It's best to plant young plants when starting a hedge. Full-grown specimens are more apt to die from transplanting stress, and finding an exact replacement can be difficult. It's easier to fill a gap in an informal hedge.

For an open, airy hedge of flowering shrubs, allow plenty of room for growth when planting. For a dense, wall-like hedge, space the plants more closely. You may find it easier to dig a trench rather than separate holes. To ensure your hedge will be straight, tie a string between stakes at each end to mark the trench before digging.

Broad-leaved plants used as a formal hedge need early training to force dense growth. For a thick, uniform hedge, reduce new shoots on the top and sides by one-third or more each year until the hedge is the desired size. Cutting a formal hedge properly is a challenge. Stand back, walk around, and recut until you get it straight—just like a haircut. Shear often during the growing season to keep it neat.

Needled evergreens require a different technique. Avoid cutting off the tops of evergreens until they reach the desired height. Shear the sides once a year, but never cut into the bare wood.

Prune informal hedges according to when they bloom. Do any needed pruning soon after flowering. Use thinning cuts to prune selected branches back to the next limb. Heading cuts that nip the branch back to a bud encourage dense, twiggy growth on the outside. To keep informal hedges vigorous, cut two or three of the oldest branches to the ground each year.

For fast, dense growth, prune in spring. This is also a good time for any severe shearing or pruning.

Care and Maintenance

The most important thing you can do for your trees and shrubs is plant them in the right spot and with great care. Carefully selected and planted trees and shrubs need only occasional attention, especially once they become well established.

During the first year after planting, water each week when less than 1 inch of rain falls, especially in summer and fall. Water to thaw the ground, and provide water for the leaves of evergreen trees during warm winter weather.

The mulch you applied at planting time will gradually decompose. Replenish it as needed, but only use a few inches. To avoid rodent problems and to encourage good air circulation, keep the mulch away from the trunk.

Small, yellow leaves, premature fall coloration, stunted twig growth, or too few flowers or fruits often indicate a nutrient deficiency. Your trees will generally receive enough fertilizer if they are located in a lawn that you regularly fertilize. If your trees are located in isolated beds, in areas surrounded by paving, or in containers, you may need to apply compost or a balanced organic fertilizer. Simply broadcast the needed fertilizer on the soil surface.

Most trees are too large for you to provide them with special winter protection such as a burlap enclosure. If snow or ice loads bend the trees' branches, avoid vigorously shaking the branches to remove the ice or snow. Frozen, brittle branches can easily break. Either allow the ice or snow to melt away naturally or very gently sweep it off.

Pruning and Training

Pruning is both a science and an art—and probably the least-understood gardening practice. A properly pruned landscape shows off each plant at its best. Well-pruned trees and shrubs produce more or better fruit and flowers. Pruning can improve the health of an ailing shrub, make trees stronger and safer, channel growth away from buildings or traffic, and restore a sense of order to an overplanted or overgrown yard.

Prune young trees at planting time and as they grow, to correct structural problems and improve their form. Training a young tree with several years of judicious pruning leads to a structurally sound, well-shaped mature tree.

After a few years, begin the limbing-up process if the tree is planted where passersby will walk below it. Remove the lowest branch or two by sawing through the limb just before the branch collar. Repeat every year until the lowest branches are high enough to permit easy passage. About five or six years after planting, thin to open up the canopy, reducing wind resistance and allowing light to reach the interior. If your tree is intended to block an undesirable view, use heading cuts to encourage denser branching.

As your shrubs grow, you'll need to prune them to control their size, rejuvenate old plants, repair damage, remove pests, and control flowering and fruiting.

Maintain the natural form of your shrubs by pruning back to outward facing buds or removing whole branches. Shearing

Showy Trees and Shrubs

Trees and shrubs can add color and diversity throughout the year. Flowering trees bring the beauty of flowers to your landscape, while many shrubs add four-season interest with their attractive foliage, colorful berries, or unusually colored or textured bark.

Small Flowering Trees

The list that follows is arranged by time of bloom, beginning with trees that flower in early spring and progressing through summer-blooming trees. The plant name is followed by flower color.

Serviceberries (*Amelanchier* spp.): white

Cornelian cherry (*Cornus mas*): yellow

Eastern redbud (*Cercis canadensis*): pink

Chinese redbud (*Cercis chinensis*): magenta

Star magnolia (*Magnolia stellata*): white to pale pink

Saucer magnolia (*Magnolia x soulangiana*): white to wine

Flowering dogwood (*Cornus florida*): white, pink

Callery pear (*Pyrus calleryana*): white

Crab apples (*Malus* spp.): white, pink, red

Carolina silverbell (*Halesia carolina*): white

Kousa dogwood (*Cornus kousa*): white

White fringe tree (*Chionanthus virginicus*): white

Japanese snowbell (*Styrax japonicus*): white

Golden-chain tree (*Laburnum x watereri*): yellow

Japanese tree lilac (*Syringa reticulata*): white

Golden-rain tree (*Koelreuteria paniculata*): yellow

Japanese pagoda tree (*Sophora japonica*): creamy white

Crape myrtle (*Lagerstroemia indica*): white, pink, lavender

Sourwood (*Oxydendrum arboreum*): white

Japanese stewartia (*Stewartia pseudocamellia*): white

Franklinia (*Frankfinia alatamaha*): white

Showy Shrubs

To add year-round interest to your home landscape, try planting a few of the plants from this list. The plant name is followed by features and seasons of interest.

Barberries (*Berberis* spp.): summer and fall foliage, flowers, fruit; all seasons

Blueberries (*Vaccinium* spp.): flowers, fruits, autumn color; summer, fall

Burning bush (*Euonymus alata*): fall foliage, winged bark; fall, winter

Crape myrtle (*Lagerstroemia indica*): flowers, fruits, bark; all seasons

Harry Lauder's walking stick (*Corylus avellana* 'Contorta'): leaves, flowers, twisted stems; all seasons

Mahonias, Oregon grapes (*Mahonia* spp.): evergreen leaves, flowers, fruits; all seasons

Oakleaf hydrangea (*Hydrangea quercifolia*): leaves, flowers; all seasons

Pieris (*Pieris* spp.): flowers, evergreen foliage; all seasons

Red-osier dogwood (*Cornus sericea*): flowers, bark; spring, winter

Rockspray cotoneaster (*Cotoneaster horizontalis*): flowers, fruit, growth habit; all seasons

Rugosa rose (*Rosa rugosa*): flowers, fruits; spring, summer, fall

Smoke tree (*Cotinus coggygria*): leaves, flowers; all seasons

Viburnums (*Viburnum* spp.); flowers, fruits; spring, fall

is faster than naturalistic pruning, but it destroys the natural beauty of the plant—and you'll need to do it often. Learn to read the natural shape and type of a plant and prune accordingly. Many plants combine characteristics and may need more than one pruning technique.

PRUNING CUTS

Many gardeners think pruning is a complicated task; however, most pruning comes down to making one of two kinds of pruning cuts: thinning cuts and heading cuts.

Thinning Cuts Thinning cuts remove branches totally. They open up a plant but don't make it shorter. Thinning directs growth into alternate patterns. Use thinning cuts to establish good structure of young trees and shrubs, to allow sunlight to reach the plant interior, to remove wayward branches or those that block a view, and to make a plant less likely to break under a heavy snow load.

Heading Cuts Heading cuts shorten plants and stimulate latent buds behind the cut to grow, making the plant more dense. Nonselective heading is the technique used to shape formal hedges and topiary. Branches are cut back partway along the stem, resulting in rapid, bushy regrowth just below the cut. Nonselective heading is often misapplied—resulting in forlorn, lollipop-shaped shrubs or trees that would look more attractive, and would likely be healthier, if pruned to follow their natural form.

Continued →

Selective heading, on the other hand, reduces overall size or height of a plant without changing its natural shape. The plant suffers less stress and doesn't regrow as vigorously. Selective heading combines the best of thinning and heading, but it can't be applied to all plants. The older, larger, and woodier the plant, the fewer selective heading cuts should be used.

Pruning Dos and Don'ts

Before you grab your pruning shears and head out the door, be sure you understand basic pruning dos and don'ts—the techniques that work and the mistakes to avoid.

Proper Technique Prune from the bottom up and, in the case of large plants, from the inside out. Prune out all dead wood first—an important step for health and good looks. Dead wood is easiest to spot in the summer because the branches have no green leaves.

Next look for a few of the worst rubbing, crossing branches. Leave the best-placed one of any pair. Try to keep any branches that head up and out from the center, as well as ones that fill an otherwise empty space.

Prune to open up center areas and to clean up the base of shrubs. This improves plant health by admitting light and increasing air circulation. It also has a large impact on the beauty of a plant.

1. Selective heading cuts

2. Thinning cuts

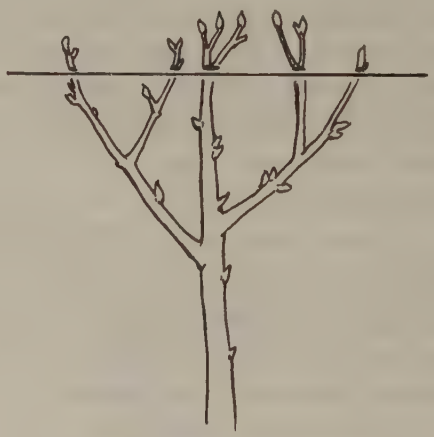
Selectively thin or head back misplaced branches: those that touch the ground, lay upon or crowd other plants, or come too close to the house, windows, and walkways.

Save any heading cuts until the end of a pruning job. Locate the longest, most unruly branch first, follow it down inside the shrub, and cut it off to a side branch inside the shrub, or a bud. Next year's new growth will be channeled into the bud or side branch.

Pruning Mistakes. The most common pruning mistake is to cut back everything in the yard in an ill-fated attempt to make it all smaller again. This stimulates an upsurge of messy regrowth, making the final solution more difficult. Tree topping, indiscriminate shearing, and overthinning are the three major or forms of "malpruning."

The cure for badly pruned plants is time. Most will reestablish their natural habits given a few years to recover.

3. Nonselective heading cuts



4. Regrowth after nonselective heading

Rehabilitative pruning can hasten the process and make plants look better. Meticulously prune all dead wood, removing all stubs. Use thinning cuts to simplify tangled branch ends. Take out entire canes. If treelike shrubs have rampantly produced suckers because of heading cuts, slowly remove the worst of them over a period of years. Let the strongest and best-laced suckers grow back into branches. Some cane-growers, like weigela, can be radically renovated by cutting them entirely to the ground. In about three years they'll regrow to mature size and bloom again. Many lovely but rampant vines, such as autumn clematis, are treated this way.

The majority of needled evergreens will not green up once they are cut back to unneedled wood. This makes their size difficult to control and radical renovation impossible.

Pruning Timetable

Plan your pruning schedule depending on what you want to accomplish. General thinning can be done in any season. Follow these seasonal guidelines:

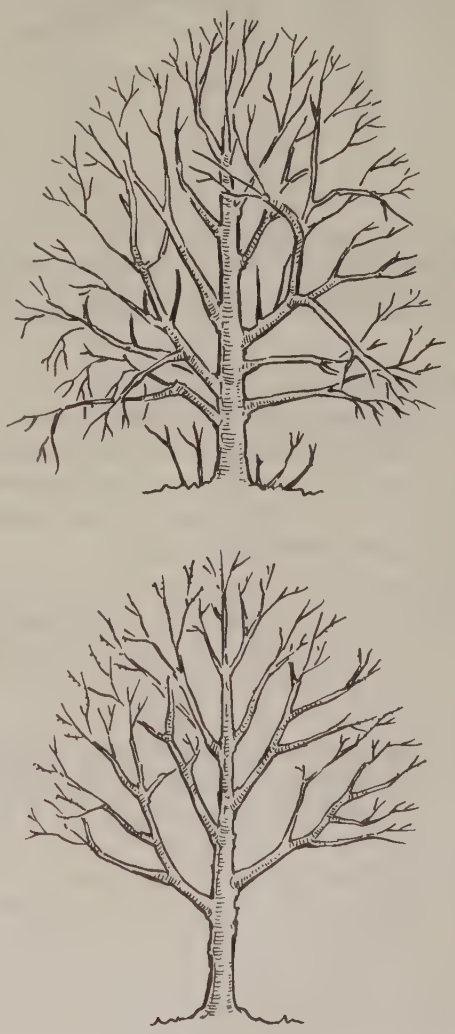
- Spring pruning stimulates the most rapid regrowth, so it's a good time for heavy pruning. Prune evergreens in spring, but avoid pruning deciduous trees as they leaf out. Prune spring-flowering shrubs such as azaleas, daphnes, and forsythias when they finish blooming so they'll have time to grow and set new buds during summer. This is essential if you are heading back all the branches to force more blooms.
- Summer pruning has a less stimulating effect on growth. Hot or dry weather is extremely stressful for plants, so avoid heavy pruning. This is a good time to tidy up plants and remove suckers and to prune summer-flowering shrubs after they bloom.
- In mid- to late fall, make only thinning cuts. Heading cuts made late in the season can stimulate soft new growth that is easily damaged in fall freezes. Don't prune plants during the period when their leaves are falling.
- Late winter is the traditional time to prune dormant plants; leaves have dropped and it's easy to see plant form. Winter pruning stimulates growth, but the results are delayed until spring. This is a good time to prune fruit trees, brambles, grapes, roses, and summer-blooming shrubs, such as butterfly bushes and hydrangeas, that form flowers on the current year's wood.

I Know You, Bud!

When pruning trees and shrubs grown for flowers or fruits, it's important to be able to distinguish vegetative buds from flower buds. Vegetative buds—those forming leaves—are usually sharper, thinner, and longer than the plump flowering buds.

Terminal or apical buds, found at the tip of a twig, can be vegetative, flowering, or mixed, and they are usually plumper than lateral or axillary buds, which are found farther down the twig.

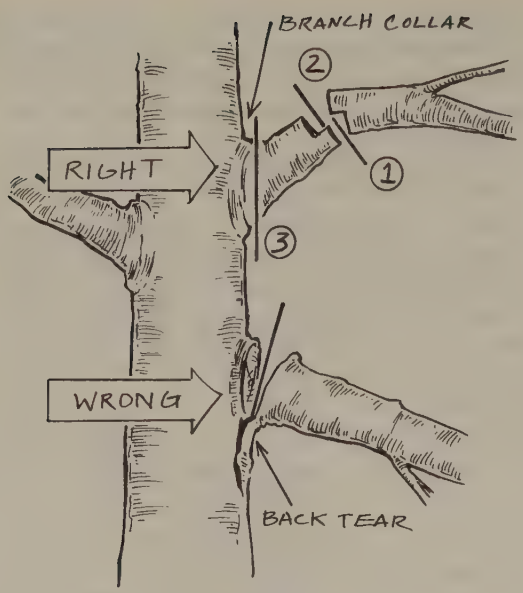
For correct timing of pruning, it's important to know where flower buds form and when they open.



Pruning a mature tree.

If you've inherited a mature tree, some judicious pruning can make it better looking and healthier. If you're not an experienced tree-climber, hire an arborist to rejuvenate your tree. Before: Dead and diseased branches, waterspouts, tight crotch angles, and rubbing or crossing branches weaken the tree's structure and make it look neglected. After: The tree has been rejuvenated and thinned out, and branches have been headed back to encourage dense new growth.

Continued ➔



PRUNING LARGE LIMBS.

Sawed from above, a large branch will tear bark from the trunk at it falls. Use the three-cut method to prevent damage. (1) About 1 foot out from the trunk, cut halfway through the branch from underneath. (2) A few inches in from the first cut, saw off the branch from the top. (3) Remove the stub by cutting along, but never into, the branch collar. On tight crotches, saw from the bottom up.

Good Tools for Good Cuts

Choose pruning tools that cut cleanly and easily. Keep the cutting edges sharp. You'll probably need only three pruning tools: pruning shears for stems and twigs, lopping shears for branches that are finger-size and larger, and a pruning saw for larger branches and crowded areas.

Pruning shears are available in two types. Anvil pruners cut with a sharp blade that closes against a metal plate, or anvil; bypass pruners work like scissors. A leather holster is a wise investment: Your hands are free, but the shears are always handy.

Lopping shears have long handles that extend your reach and give you leverage for more cutting strength. A small rubber shock absorber is a welcome addition on some models. Folding pruning saws fit nicely into a back pocket. New ARS-type saws have multifaceted blades and cut twice as easily as traditional blades. Pole pruners can be used for overhead work, but be careful of overhead wires.

The pruning head can consist of either a saw or a cord-operated hook-type shear, or some combination of the two. You may find that hedge shears are extremely useful for keeping your formal hedges neat.

Pruning Evergreens

Evergreens that are the proper size for their location need very little pruning. Their natural growth habit is interesting and attractive. To remove unhealthy or errant growth, use a thinning cut, pruning off branches nearly flush against the branch from which they originate.

Unlike broad-leaved evergreens, needle-leaved evergreens aren't quick to resprout after pruning. Take care to prune them properly. Follow these steps when pruning evergreens:

- Thin evergreens by removing branches any time of the year. Cut stray branches far enough to the inside to hide the stub. Branches cut back beyond the green needles will not sprout new growth.
- Don't cut the central leader at the top of the tree—an evergreen without its central leader will have a drastically different shape.
- Prune arborvitae, hemlocks, junipers, and yews throughout the growing season.
- Trim your evergreens gradually. If you cut off more than one-third of the total green on the plant, it may die.
- One good idea is to hold off pruning your evergreens until a few weeks before Christmas. Then use the trimmings from arborvitaes (*Thuja* spp.), boxwoods (*Buxus* spp.), cedars (*Cedrus* spp.), firs (*Abies* spp.), pines (*Pinus* spp.), rhododendrons (*Rhododendrons* spp.), and other evergreens for holiday wreaths and decorations.

Avoiding Pests and Problems

Frequent inspection of your trees will help minimize problems. Your best defenses are to buy good-quality, pest-free trees to avoid introducing pests or disease; to plant your trees in proper environments to encourage vigorous growth; to use good maintenance practices; and to minimize environmental stresses.

Biotic or pathological problems are caused by living organisms—insects, mites, fungi, bacteria, viruses, nematodes, and rodents. Abiotic or physiological problems are caused by nonliving things—improper planting and maintenance, poor soil conditions, air pollution, injury, compacted soil, construction damage, and lightning. Far more tree problems are caused by abiotic problems, which weaken trees, allowing boring insects and decay fungi to attack. If your tree shows signs of ill health, check for poor conditions that may have allowed the pest or disease to get a foothold.

The plant family bothered by the greatest number of insect and disease problems is the rose family. This large family includes such trees as crab apples, flowering pears, cherries, peaches and plums, hawthorns, serviceberries, and mountain ash. Crab apples are particularly susceptible to problems; buy only those cultivars that are resistant to the diseases rust, scab, powdery mildew, and fire blight. Other trees, such as flowering dogwood, maples, sycamores, birches, elms, locusts, and oaks, may also have numerous pest or disease problems. Ask your nursery owner for advice before purchasing.

City-Smart Trees

City trees must contend with constricted root space, compacted soil, wind tunnels between buildings, limited moisture and nutrients, high temperatures, and pollutants.

Trees used along streets, in raised planters, in median strips, or in parking lots must survive in the harshest most stressful of all landscape environments. These often-neglected trees face all the hazards of city trees and must put up with drought, paving heat, and human vandalism. Despite relentless pruning to make them fit under overhead utility lines or within narrow corridors, and even when main branches are whacked off to permit people and cars to pass by, street trees manage to survive. But all these stresses take their toll: On average, street trees live only 10 to 15 years.

In addition to resisting insects and disease, good street trees also share other characteristics. They should be "clean" trees with no litter problems, such as dropping large leaves or fruit, although sometimes, as with sycamores (*Platanus* spp.) and oaks, the litter is overlooked because of other good qualities. Avoid trees with dangerous horns or spines, such as hawthorns (*Crataegus* spp.); shallow-rooted trees that buckle paving, such as silver maples (*Acer saccharinum*); and thirsty trees, like weeping willows (*Salix babylonica*), whose roots seek water and sewer lines. Trees with branches that angle downward, such as pin oaks, also don't make the best street trees, unless they are limbed up high enough for pedestrians and traffic to pass easily. Here's a list of city-smart trees to consider. These trees are tough enough to tolerate the difficult growing conditions of city streets. All will tolerate poor soil, pollution, and droughty conditions.

Small Trees

Amur maple (*Acer ginnala*)

Flowering pears (*Pyrus calleryana* 'Aristocrat' and 'Red Spire')

Golden-rain tree (*Koelreuteria paniculata*)

Hedge maple (*Acer campestre*)

Japanese tree lilacs (*Syringa reticulata* 'Ivory Silk' and 'Summer Snow')

Sargent cherry (*Prunus sargentii*)

Tatarian maple (*Acer tataricum*)

Thornless cockspur hawthorn (*Crataegus crusgalli* var. *inermis*)

Trident maple (*Acer buergeranum*)

Medium to Large Trees

Bald cypress (*Taxodium distichum*)

Chinese or lacebark elm (*Ulmus parvifolia*)

Hackberry (*Celtis occidentalis* 'Prairie Pride')

Japanese pagoda tree (*Sophora japonica*)

Japanese zelkovas (*Zelkova serrata* 'Green Vase' and 'Village Green')

London plane tree (*Platanus* x *acerifolia* 'Blood good')

Sawtooth oak (*Quercus acutissima*)

Silver linden (*Tilia tomentosa*)

Sycamore maple (*Acer pseudoplatanus*)

Thornless honey locusts (*Gleditsia triacanthos* var. *inermis* 'Skyline' and 'Shade master')

Upright English oak (*Quercus robur* 'Fastigiata')

Upright European hornbeam (*Carpinus betulus* 'Fastigiata')

Upright ginkgo (*Ginkgo biloba* 'Fastigiata')

Willow oak (*Quercus phellos*)

Whenever a disease or insect problem is seen, try to control it by removing the pest or the affected plant part. Don't compost or burn infected plants. Remember to sanitize tools after pruning infested or infected wood by cleaning them with a 10 percent bleach solution (1 part bleach to 9 parts water).

Insects Most insect problems of trees are caused by a relatively small number of insects and mites (technically classed as arachnids). These pests have their preferences: Some primarily damage leaves, and others primarily damage branches and trunks.

Insects eat leaves and suck plant sap from them. The larvae of moths and butterflies, such as bagworms, cankerworms, webworms, tent caterpillars, and gypsy moths, are especially voracious leaf-eaters. Highly noticeable webs of Eastern tent caterpillars and fall webworms protect the larvae from predators while they munch your leaves. Although the nests are unsightly, trees usually recover from infestations. Remove and destroy any webs you can reach.

Gypsy moth populations rise to a peak in cycles of several years, causing almost complete defoliation in areas of heavy

Continued ➔

infestation. Hand-picking and spraying BT (*Bacillus thuringiensis*) are the best defenses against severe attacks of gypsy moths. In winter, check your trees for the light brown egg masses, and scrape them off into a container of ammonia.

Other major insect pests that damage leaves are aphids and adelgids, various beetles and bugs, miners, scales, and spider mites.

Insects are always present on trees. Populations must be extreme before the tree suffers any real damage. Don't rush to the sprayer as soon as you spot a caterpillar or two. Remember, the goal is a healthy tree, not complete insect annihilation. Learn to recognize harmful pests and the signs of infestation: curled leaves, stunted growth, deformed flowers.

Try handpicking and pruning off affected branches before you reach for other controls. Even BT is not innocuous. It does kill gypsy moth larvae, tent caterpillars, and other undesirables—but it will also kill any other caterpillar that happens to eat a tainted leaf, including the beautiful luna moth, giant silk moths, and dozens of others.

Stems are damaged when insects such as borers and scales either bore into them or feed on them. Cicadas cause stem damage when they lay their eggs into slits in twigs. Microscopic wormlike nematodes also cause problems on the roots of many trees.

Diseases Tree diseases occur on leaves, stems, and roots. Many pathological diseases are difficult to distinguish from physiological problems. For instance, while fungi and bacteria can cause leaf spot diseases, spots on tree leaves can also be caused by nutrient deficiencies, improperly applied pesticides, road salts, and even drought. Be careful to properly identify a tree problem before you look for a control or corrective measure.

Most tree diseases are caused by fungi, although a few major diseases, such as fire blight on pears and other members of the rose family, are caused by bacteria. Flowering peaches and plums are also bothered by viral diseases.

Diseases of tree leaves are generally spots, anthracnoses, scorches, blights, rusts, and mildews. You will see them on your trees most frequently during moist weather and when plants are under environmental stress. Diseases of tree stems are generally cankers, blights, and decays. You will see these diseases when trees have been damaged by improper pruning, mechanical injury, and other maintenance and environmental factors. Root rots occur when soils are poorly drained and may be intensified if roots have been injured by such things as construction damage and trenching.

Physical Damage You can damage a tree by nailing items to it or gouging it with a lawn mower. Animals also damage trees. Birds may occasionally break branches or drill branches, looking for sap or insects. Moles damage your trees by cutting the roots as they tunnel, and voles actually feed on the roots. Mice and rabbits damage trees by feeding on the bark. Deer damage trees by browsing on young branch tips and by rubbing their antlers on the trunks and branches.

Handle your trees gently. Avoid lawn mower damage by using mulch or beds of groundcovers to surround the trunk. A cat that patrols outdoors now and then is one way to control rodents. Fence to keep out deer.

Trees and Shrubs the Low-Maintenance Way

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

Few landscape options require as little maintenance as a planting of well-chosen and carefully planted trees and shrubs. But before you rush to fill your yard with trees and shrubs, note those important qualifiers: well-chosen and carefully planted.

In this chapter, you'll learn how to choose healthy trees and shrubs that will thrive in your landscape. Since trees and shrubs are a long-term investment that can either be carefree or add loads of maintenance nightmares, it pays to do a little research, ask questions, and choose carefully. You'll also learn how to plant and care for your trees and shrubs properly.

10 Tips for Easy Trees and Shrubs

1. Choose disease- and pest-resistant species and cultivars. Check with nursery owners and your county's extension office to find out which plants are best for your area.
2. Choose plants adapted to your site's soil, exposure, and other conditions. A tree that is stressed by factors such as drought, poor soil, or not being adapted to the site you've selected is more susceptible to pests and diseases that otherwise might not trouble it.
3. Choose plants whose mature size and form fit your spot. A tree whose size and shape are suited to your spot won't need pruning. A large tree in a small space will overwhelm the landscape and pose expensive problems such as limbs overhanging your roof or blocking windows.
4. Buy from reputable nurseries. Plants from grocery and hardware store lots are usually inferior and poorly cared for.
5. Give your plants room to grow. Space them far enough apart to allow them to reach full size without crowding.
6. Choose drip irrigation where watering is required.
7. Choose trees with small or winter-persistent leaves to minimize fall raking chores.
8. Make mowing easier by consolidating trees and shrubs in islands or borders rather than dotting your yard.
9. Underplant trees and shrubs with groundcovers or shade-tolerant perennials to minimize mulching chores.
10. Mulch around trees without underplantings to prevent weeds and mowing hassles.

Smart Shopping: Look Out for Losers

Healthy, vigorous trees that resist pests and shrug off diseases are a joy in any landscape. Unfortunately, when you shop, it pays to remember that the most widely available trees aren't always best to plant. Trees that originally had few problems can develop them if they are too widely planted because pests or diseases move in to take advantage of the dense populations.

To avoid a problem, stay away from the "losers" listed here. Although some have appropriate uses, their troubles largely outweigh their benefits.

American mountain ash (*Sorbus americana*)

Cockspur hawthorn (*Crataegus crus-galli*)

English oak (*Quercus robur*)

European mountain ash (*Sorbus aucuparia*)

European white birch (*Betula pendula*)

Flowering crabapple (*Malus cultivars*). Disease-resistant crabapples are available, but disease-prone cultivars are sold.

Lombardy poplar (*Populus nigra* 'Italica')

Purple plums (*Prunus cerasifera cultivars*)

Russian olive (*Eleagnus angustifolia*)

Siberian elm (*Ulmus pumila*)

Silver maple (*Acer saccharinum*)

Thornless honey locust (*Gleditsia triacanthos* var. *inermis*)

White ash (*Fraxinus americana*)

White poplar (*Populus alba*)

Save Work with Wise Buys

Woody plants are the durable goods of your landscape. Each one represents a long-term investment that helps determine how attractive and how easy to maintain your property is. With a healthy start and a small, but consistent, amount of care, the trees and shrubs you plant in your yard will become an enduring source of shade, shelter, and beauty.

Because trees and shrubs are such long-term investments, it makes sense to shop carefully when you choose them. Taking time to make smart selections not only ensures that you're satisfied with the plants you've chosen, it also helps reduce the amount of care you'll need to provide over their long lives.

START WITH THE SELLER

Your low-maintenance tree or shrub begins its life in a nursery. Make sure the nursery you buy from, whether mail-order or local, has a reputation for quality plants and intelligent service.

Figure out just what and how many plants you need before you buy. This clear idea is your best protection against impulse buying. Before you shop, call around to find which nurseries have the plants you're looking for, what size they are, how they've been grown, and how much they cost.

INSPECT AND DETECT

At the nursery, inspect each prospective purchase thoroughly. Here's what to look for.

- Examine leaves, stems, and bark for signs of disease or insects.
- Choose plants with foliage that's turgid and green, not drooping or yellowed.
- Inspect the roots, too. If the plant is in a container, tip it out carefully or ask nursery personnel to do this for you. No soil should fall away from the root ball, and a vigorous mass of roots should be visible at the soil surfaces that were covered by the pot.
- Check the moisture of the growth medium. An extremely dry root ball may mean that the plant has been poorly cared for and unnecessarily stressed.

Trees (and Shrubs) to Go: Have Them Your Way

You can buy woody plants in the following three forms: bareroot, containerized, or balled-and-burlapped (B&B). Each option offers advantages and disadvantages in terms of its effect on planting and aftercare. Use this table to help you choose how you'd like to purchase your plants and to guide you in caring for any plants you buy, no matter how they arrive.

Form	Advantages	Disadvantages
Bareroot	Least expensive; cheapest to ship via mail order.	Need immediate planting or heeling-in; may arrive with insufficient root mass to allow growth; careful packing and shipping required to ensure plants don't dry out; for spring or fall planting only.
Containerized	Established root mass; easy to maintain if you can't plant right away; can plant any time during growing season if aftercare is adequate; less expensive than same size plant balled-and-burlapped.	Some plants slow to root out into soil; soilless mix around roots resists watering even after planting; more expensive than bareroot.
Balled-and-burlapped (B&B)	Usually heartier than comparably sized containerized plants; already hardened to outdoor conditions; permits planting of larger plants; usually establish more quickly.	Heavy and more difficult to transport and handle; most expensive; if wrapped in rotproof burlap (usually dyed green), must be unwrapped; large size of plant in relation to rootball may necessitate staking.

Continued ➔

- Finally, make sure the individual plant you've chosen has good form. A misshapen plant will at least require more pruning and shaping, and at worst may never outgrow its homeliness.

MAKE SURE ROOTS MEASURE UP

Balled-and-burlapped (B&B) trees and shrubs are field grown, usually dug while dormant, and their root balls wrapped with burlap. The biggest hazard of buying a B&B tree is that it may have an undersize root ball. The rule of thumb is that the root ball should be 1 foot in diameter for every inch of the trunk's diameter at its base. There is no comparable rule for shrubs, but the bigger the ball, the faster the plant will establish. Undersize root balls are a bigger hazard for trees, whose roots extend far beyond their driplines. The average B&B tree retains only 5 percent of its original root mass.

LOOK FOR SIGNS OF LIFE

If a B&B plant is dormant, scratch its bark in a few places to make sure that it is alive throughout. Live bark scratches easily to reveal green tissue beneath. Ask nursery personnel to pull back the burlap to let you check for root girdling, a condition in which a plant's own circling roots can choke it to death. Inspect the root ball for signs of cracking, and touch the soil to see that it's moist. Don't buy a plant with a cracked or crumbled root ball.

If the root ball is wrapped in rotproof burlap, ask if the nursery will remove it and rewrap the ball in untreated burlap. This will allow you to plant without removing the wrapping.

STAY AWAY FROM STRANGERS

Girdling roots can cause your trees and shrubs to mysteriously decline and die. Check new tree and shrub purchases for signs of circling roots. As a plant grows, such roots can tighten around its stem, gradually cutting off its supply of water and nutrients.

Make Your Trees Work Harder: Look for 4-Season Appeal

Real landscape workhorses don't just sit there and grow, they also add visual appeal—with flowers, fruits, fall color, form, and/or attractive bark. Their blossoms or unusual foliage may allow you to spend less time tending annuals or perennials as sources of color. Their fruits may lure birds or other wildlife to brighten your yard and entertain your family.

Paint a cheery tableau outside a window with a combination of evergreen and fruit-laden shrubs. Shrubs with persistent fruits add color and attract birds to the winter landscape. An added bonus: Many make great cutting materials for holiday wreaths and arrangements.

Hedge Your Bets against High Hedge Maintenance

Lowering the amount of maintenance your landscape needs doesn't mean giving up on hedges. It simply requires you to give up on the notion that a hedge must be closely clipped and geometrical—pruned to within an inch of its life—to keep it under control and tidy. In addition to the huge amount of maintenance they require, clipped, formal hedges all too often end up top-heavy, their shaded lower foliage dropping off to reveal the unsightly, knobby knees beneath.

Instead of slipping into this time-worn, high-maintenance groove, give yourself an attitude adjustment and plan on an informal, low-maintenance hedge. The plants listed below make excellent informal hedges; they maintain a natural unshorn shape that is upright to mildly arching with little or no pruning.

For evergreen hedges, consider one of the new hybrid boxwoods—*Buxus* 'Green Gem,' 'Green Velvet,' or 'Green Mountain,' which are all hardy from Zones 5 to 8. Hollies also make fine evergreen hedges. Consider *Ilex glabra* 'Nordic' ('Nordic' inkberry), hardy in Zones 5 to 9, or one of the blue hollies, especially *Ilex x meserveae* 'Blue Prince' and 'Blue Princess,' hardy in Zones 5 to 8. (Plant one 'Blue Prince' for every several 'Blue Princess' plants to get berries.)

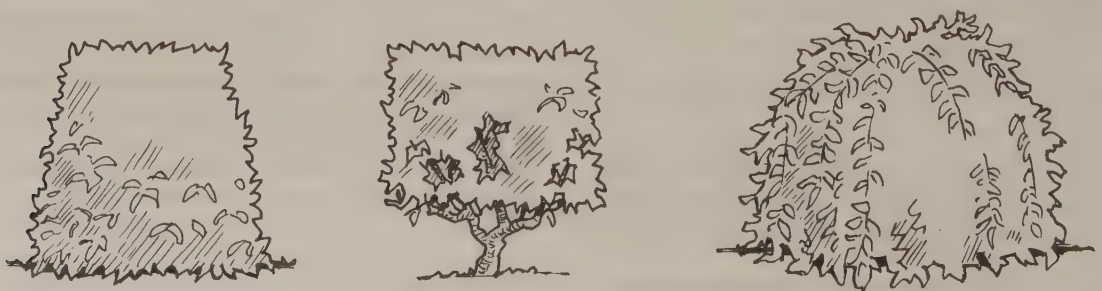
PLANTS FOR DECIDUOUS HEDGES

'Brilliantissima' red chokeberry (*Aronia arbutifolia* 'Brilliantissima'). Zones 4-9.

Korean barberry (*Berberis koreana*). Zones 3-8.

Mentor barberry (*Berberis x mentorensis*). Zones 5-9.

Nanking cherry (*Prunus tomentosa*). Zones 3-5.



Maintaining a formal hedge requires careful pruning to keep it looking its best. It's especially important to keep the top of the hedge narrower than the bottom to prevent shading out of the lower branches. To eliminate this type of tedious maintenance, plant an informal hedge of loosely arching shrubs like forsythia or Japanese kerria (Kerria japonica), and put your hedge clippers away for good.

Regel privet (*Ligustrum obtusifolium* var. *regelianum*). Zones 4-8.

Rugosa roses (*Rosa rugosa cultivars*). Zones 3-7.

Summersweet (*Clethra alnifolia*). Zones 5-9.

Winter honeysuckle (*Lonicera fragrantissima*). Zones 5-9.

'Winter Red' winterberry (*Ilex verticillata* 'Winter Red'). Zones 4-9.

Keep Maintenance in Mind at Planting Time

Plant islands for easy maintenance. Instead of scattering plantings, group trees together into freeform islands in the lawn. Underplant with shade-tolerant shrubs and groundcovers, then mulch for low-maintenance planting you'll enjoy for years to come. Use edging strips to keep lawn grass from overtaking your islands, and mow around them with a single pass of the mower.

You can plant a yard full of easy-care, low-maintenance trees and shrubs and still end up with a maintenance nightmare. That's because the design you choose for your plantings can have a big effect on how much work they'll take to maintain. Keep these design principles in mind when you're deciding where to plant new trees and shrubs.

Eliminate fenceline hassles with mixed plantings. Plantings of trees, shrubs, groundcovers, and easy-care perennials can eliminate tedious weeding and trimming along fences. Just select plants suited to the site, then plant and mulch. If you need to be able to paint your fence occasionally or need access to plantings from the back, leave a 2-foot maintenance path between fence and plantings.

Prudent Planting Pays Off

Planting properly will save you scores of hours of maintenance in the future. It can also save you money replacing plants that perish because they were poorly planted. Follow the suggestions below to get your trees and shrubs off to a great start.

Whether you're planting bareroot, containerized, or balled-and-burlapped (B&B) stock, prepare the planting area before you dig your hole. Remove all unwanted vegetation and turn and loosen the soil. Soil requirements of different trees and shrubs vary widely. Whenever possible, match the plant to your existing soil. If your soil is inadequate for the plant you've chosen, incorporate soil amendments over the entire planting area, not just in the planting hole. When planting a single shrub, renovate an area at least 3 feet in diameter. For a tree, renovate an area at least 5 feet in diameter.

PLANTING BAREROOT STOCK

Mail-order trees and shrubs are usually shipped bareroot in spring. Here's how to plant them.

Inspect your plants as soon as they arrive. Bareroot plants should be carefully packed in moist materials, and their bark should show no signs of shriveling. The roots should look husky and healthy. If the root mass looks extremely small for the size of the plant, contact the nursery immediately and register your dissatisfaction.

Take care before planting. After unpacking them, soak your plants in a bucket of water or weak compost tea for 12 to 24 hours. If you can't plant immediately, bury them almost completely in a shady spot for no more than a week (a process called "heeling in"). Trim all broken or damaged roots, and prune back the top by one-third to one-half before you plant. Never allow the roots to dry out, even for a few minutes.

Plant well. Spread the roots of bareroot plants over a mound of soil in the bottom of the planting hole. Look for a soil line on the stem and use it as a planting depth guide. Backfill carefully with unamended soil, making sure that finely crumbled soil is in contact with the roots. Pat the soil down firmly around the roots, form a basin around the plant, and water several times after planting, plunging the hose end underground to fill air pockets. Apply a 2-inch layer of mulch around the plant to conserve water and weeds.

PLANTING CONTAINERIZED STOCK

Use these tips to get container-grown trees and shrubs off to a good start.

Soak before planting. Plunge each container into a bucket of water until the root ball is saturated.

Score the roots. Use a knife or screwdriver to cut the roots to a depth of ½ inch at intervals around the container. This encourages the roots to grow outward into the soil.

Dig the right hole. Dig a planting hole about twice as wide as the container, deep enough so that the surface of the root ball will be just below soil level. If drainage is poor, make the hole shallower so you have to mound the soil around the plant to cover it. Place the root ball on a slightly elevated platform of soil in the bottom of the hole. The surrounding moat will collect water to be wicked up from the bottom of the root ball—water tends to flow around the soilless mix used in most containers.

PLANTING BALLED-AND-BURLAPPED STOCK

Here's how to get B&B plants in the soil and off to a good start.

Always support the root ball. Never move a B&B plant by grasping the trunk or stem. Doing so requires the roots to support the weight of the soil and will break them. Use a dolly or a cart to move B&B plants too heavy to carry easily. Make sure the root ball is moist, but not wet, before you plant.

Check the burlap. Check to see if your plant is wrapped in a plastic burlap material or true burlap, which is biodegradable. Remove plastic burlap entirely; it can restrict root growth. Also cut away planting "cages" that may contain the roots. Real burlap will wick moisture away from the roots if it's exposed, so pull it partially away from the ball and bury it when you backfill.

Continued ➔

Study the roots to dig the right hole. Dig a hole two to three times as wide as the root ball, and deep enough so that the uppermost roots emerging from the stem are just below soil level. Open the burlap slightly and pull away enough soil to locate these roots. In the process of digging the plant, additional soil is sometimes thrown on top of the ball. For this reason, it's easy to inadvertently plant B&B stock much too deeply. Especially in heavy soils, this is one of the most common causes of death in B&B plants. In very heavy soils, dig the hole shallow enough so that you must mound the soil around the upper third of the root ball.

Roll or gently lower the bail into the hole. Dropping B&B stock can fracture the root ball and seriously compromise the plant.

Plan for Post-Planting Care

Your new tree or shrub is most vulnerable in its first year of life. Use this simple post-planting care checklist to get your plants off to a vigorous start.

Water, water, water. Inadequate watering is the number-one cause of new plant death. Most new plants need about an inch of water per week during the first growing season.

Mulch. Keep an adequate layer of mulch around your new plant to prevent weed competition.

Feed. When the plant puts out new growth, feed it with some weak manure tea or compost tea. Or just pull back the mulch and apply a layer of compost or rotted manure around the root zone. Replace the mulch over it.

Minimal Maintenance Methods

A well-chosen, carefully planted tree or shrub will need little maintenance beyond its early years. In most cases, your plant will flourish surprisingly well with benign neglect. But you may occasionally need to intervene. Here's a rundown of the care you can expect and tips for minimizing it.

WATERING

After the first year, your trees and shrubs should not need supplemental watering, except during periods of unusual drought. The exceptions are azaleas and rhododendrons, which need steady moisture to look their best. If you can't keep them well watered, you'll be better off without them.

If you want to plant in a dry spot, choose plants adapted to drought. If your spot is boggy, choose wet-tolerant plants.

If you want to install an irrigation system for your trees and shrubs, stay away from overhead irrigation. Opt instead for one of the many drip irrigation systems available.

PRUNING

The best way to minimize pruning maintenance is to put yourself through an attitude adjustment. Forget about closely shorn globes, cones, and gumdrops. Focus instead on the graceful beauty of a shrub's natural form and learn to appreciate it. Disabuse yourself of the notion that all plants need pruning to make them look "neat" or to keep them under control. Choose shrubs and trees whose ultimate form and size are suited to the spot you have in mind.

Stop, don't top! Never, ever perform—or have performed—on your trees the disgraceful disfigurement known as "topping." This practice causes dangerous, weak-wooded trees that decline gradually and eventually die. If a tree is interfering with power lines, remove individual limbs, transplant the tree, or cut it down.

Leave limbing in limbo. Forget about "limbing up" your evergreens. This practice of removing the lower limbs of evergreens spoils their graceful form and creates more mowing for you. Let those branches sweep the ground and they'll provide their own mulch zone around the tree.

Occasionally, of course, the need to do some light pruning will arise.

FERTILIZING

Most trees and shrubs will grow just fine—albeit more slowly—without any fertilization. Applying 3 to 4 inches of compost to the root zone once or twice a year is helpful. Occasionally, in very lean soil, more help is needed. Manure tea gives a quick boost to starving plants; a mulch of grass clippings provides a more slowly released nitrogen supply.

Grow them lean and mean. Too much nitrogen fertilizer promotes lush growth that is very tender and disease susceptible. Even resistant trees and shrubs can fall prone to diseases like fire blight on a nitrogen-rich diet. In Zones 3 through 7, withhold nitrogen fertilizer from your woody plants after the 4th of July to give new growth from the spring a chance to "harden" and to curtail additional lush, tender growth.

Think Small

Instead of planting a full-size tree, consider the trees listed here. They range from 10 to 25 feet tall—just right for filling in a limited-space landscape with little or no pruning.

You can screen an area quickly and easily with multi-stemmed plants. In this list, trees with multi-trunk tendencies are marked with an asterisk (*).

Callery pears (*Pyrus calleryana cultivars*, especially 'Aristocrat' and 'Autumn Blaze'). Zones 4-8.

Chinese dogwood (*Cornus kousa* var. *chinensis cultivars*). Zones 5-8.

Crape myrtles (*Lagerstroemia indica* hybrids and cultivars)*. Zones 7-9.

Downy serviceberry (*Amelanchier arborea*)*. Zones 4-9.

Eastern redbud (*Cercis canadensis*). Zones 4-9.

Flowering crabapples (*Malus cultivars*). Zones 3-8.

Japanese snowbell (*Styrax japonicus*). Zones 5-8.

Japanese stewartia (*Stewartia pseudocamellia*). Zones 5-8.

Japanese tree lilac (*Syringa reticulata*). Zones 3-7.

Mountain silverbell (*Halesia monticola*)*. Zones 5-9.

Pagoda dogwood (*Cornus alternifolia*). Zones 3-7.

Star magnolia (*Magnolia stellata*)*. Zones 3-8.

White fringe tree (*Chionanthus virginicus*)*. Zones 3-9.

The Secret's in the Soil: Rhododendrons and Azaleas Demystified

There's no denying the beauty and versatility of rhododendrons and azaleas. Their bountiful, beautiful flowers and attractive, often evergreen foliage make them a welcome addition to nearly any landscape. It's no wonder that so many gardeners are willing to struggle against less-than-ideal conditions to grow them.

If rhododendrons and azaleas are must-have plants in your landscape, pay close attention: Rules about careful siting go doubly for these plants. Although they are neither more tender nor more difficult to grow than many other landscape plants, rhododendrons are very particular about the conditions they grow in. Success is a matter of choosing plants appropriate to your area, preparing the soil adequately, and supplying adequate moisture.

In the mid-Atlantic, the South, or the Pacific Northwest, soil and weather conditions make it relatively easy to grow just about any and all rhododendrons and azaleas. Gardeners in other regions need to exercise more care in selecting plants and sites. In northern zones, for example, it's important to steer clear of selections whose flower buds are not hardy enough to withstand the cold. After all, what's the use of growing a rhododendron that never blooms?

Choose a site in partial shade for your rhododendrons and azaleas. Sheltering them from drying winter winds benefits evergreen types. But don't try to grow rhodies under maples; their greedy roots won't give timid rhododendrons a chance.

DIG IN FOR SUCCESS

If you want to grow rhododendrons and azaleas in anything less than their native moist, rich, woodland soil, there's no getting around doing some soil preparation. If you have clay soil, add equal parts of coarse sand and organic matter (leaf mold, compost, pine bark, rotted manure, or rotted sawdust) and incorporate thoroughly. Add plenty of amendments, so that the resulting area is mounded up a few inches. Test the soil pH. If it's above 6.0, incorporate sulfur to bring it down into the 5.0 to 6.0 range. Plant your rhododendrons and mulch with 3 to 4 inches of pine bark, rotted sawdust, or pine needles. Spread out the roots on the surface of the root ball to stimulate them to grow outward, something rhododendrons' roots are very slow to do.

In sandy soils, forget about adding sand, but double up on the organic matter. Avoid creating a mound that will contribute to the already rapid drainage. Sandy soils are often acidic; don't routinely add sulfur without checking the pH.

Have a source of water handy, as rhododendrons need pretty constant moisture throughout summer. Drip irrigation is best. And remember to water evergreen rhododendrons thoroughly before the ground freezes to help ward off winter desiccation.

For Problem-Free Evergreens, Heed These Tips

Needled evergreens are among the most widely planted trees and shrubs. As with many popular plants, they have been heavily overplanted and often badly used. Use the tips below to minimize problems.

Choose carefully. Pines, in particular, have become host to a plethora of pests. Minimize problems by consulting with experts on the most durable evergreens for your area. Also ask about evergreen alternatives to the most commonly planted spruces and pines.

Avoid streetside sites. Many pines and most spruce cannot tolerate salt spray from vehicles whooshing along a salted street in winter. Browning foliage on the street side of a planting is a surefire sign of salt damage.

Shelter plants from winter winds. Pick a site that is sheltered from prevailing winter winds, which can shrivel evergreens' foliage. And place them away from south-facing windows so they don't block welcome winter sun.

Consider size at maturity. Whether you're planting spruces, pines, yews, or junipers, don't be fooled by their cute, compact forms in containers. It's all too easy to take a small plant home, plop it in place next to your foundation, and end up shearing and hacking at it to keep it in bounds for the rest of its life. To avoid future pruning nightmares, look at height and spread, and space plants accordingly. Fill in between small plants with perennials or groundcovers for a finished look while you wait for plants to grow.

Buy plants that behave. If you need a low-growing or compact plant for a special site, don't depend on pruning—look for cultivars of evergreens that will mature at the height you want. Cultivars of creeping juniper (*Juniperus horizontalis*) and western

Continued ➔

red cedar (*J. scopulorum*) mature at heights from several inches to 1½ feet. Low-growing pines, spruces, and yews are also available, so don't settle for what's most commonly available.

Adding Shade Trees and Shrubs

Larry Hodgson

The first thing most gardeners consider when they want to add more shade is planting trees. The very name "shade tree" says it all: They are trees purposely planted to create shade.

Adding trees to any landscape is often seen as the finishing touch, but landscape planners tend to see trees and large shrubs not as final details but as the actual "bones" of the garden—the structure around which it will be based. A large home, especially, can look as if it had been dropped from the sky by extraterrestrials when it sits on a bare lawn or is surrounded only by low flowerbeds or a knee-high hedge. Some height is needed to integrate it into its surroundings, and the most logical and least expensive way of adding height is by planting trees. Even on smaller lots with limited yard space, trees are essential—although the choice of trees will likely be radically different, and there will probably be fewer of them.

Studies show again and again that trees add financial value to your home, something you may want to consider if you intend to sell your home someday. You can spend $10,000 renovating the bathroom and barely recuperate the cost when you sell, yet planting a $50 tree can add 10, 20, 50—or more!—times that amount to the value of your home.

There was a time when a shade tree meant a huge, spreading 50-foot silver maple (*Acer saccharinum*) or European beech (*Fagus sylvatica*), but times have changed. Smaller lots mean that there is rarely enough room for a 50-foot monster in suburbia—or, if there is, there may be room for only one. Instead, smaller trees have come into the fore. Crabapples (*Malus* spp.) and saucer magnolias (*Magnolia* x *soulangeana*) are considered fine shade trees even though they rarely reach more than 25 feet in height. The important thing about a shade tree is that you should be able to set a lawn chair under it to enjoy the shade. Narrow, columnar trees, like upright English oak (*Quercus robur* f. *fastigiata*), don't cast much usable shade: You'll have to put your lawn chair on wheels and chase after the shade as it moves over the lawn. For good shade, look for trees with spreading or arching branches or a rounded top. You'll find that some of the smaller ones will need "limbing up" (having their lower branches removed) as they grow to make good shade trees, or the only way you'll get under them is by crawling!

Shading with Shrubs

Shrubs can create shade, and they have added benefits: They grow and fill in faster than trees, yet their roots are not so aggressive as to choke out lower plants. Also, their shade is not dense enough to create problems, largely because sunlight reaches both around and over them to ensure some sun to the plants they protect.

Fast and Easy Shade

Growing your own shade by planting trees and shrubs is wonderful but takes time. If you just can't wait, you can also build your own shade structure. This usually costs considerably more than planting trees and tall shrubs, but it does produce fast results.

Although you can use a durable wood such as cedar for the frame of the structure and attach lattice or fencing as screening, there is practically an unlimited number of possible materials to use for both structures and coverings (including metal, plastic, fiberglass, and resin). You can design the structure to let in a little light or a lot, depending on your needs. And you can add climbing plants to provide further seasonal shade as needed.

FENCES AND TRELLISES

These comparatively inexpensive structures can provide localized shade for plants to their north. The shading effect of fences may be limited by municipal height regulations (6 feet is a common maximum), so check with your town's planning department before proceeding. Trellises tacked onto walls provide little shade, of course, but you can stand them upright to provide interest in the landscape or link them together for more impact.

ARBORS AND PERGOLAS

An arbor is usually a rather modest lattice structure, often covering a path or walkway, sometimes incorporating a bench, with an open or lattice roof. It was originally designed as a support for climbing plants, but it is now often used as an ornamental structure in its own right. It becomes a pergola when it is taller and more elaborate, with parallel colonnades supporting an open roof of girders and rafters. Both supply fairly good shade from the start, depending on the density of the rafters and lattice, and can provide deep shade when they are covered with climbing plants.

GAZEBOS, LANAIS, AND SHADEHOUSES

More elaborate shading structures can incorporate a raised or patio floor and an open or closed roof and are often used for relaxation or entertaining.

The original gazebo was often a six-sided outbuilding designed for gazing out over the garden in poor weather, but it has evolved to encompass a wide range of garden pavilions. Some have screen or latticework sides used for climbing plants, and they often contain a host of potted plants summering outdoors.

Lanais are like vast screened-in porches and may house a swimming pool and container gardens. They're very popular

in hot climates where indoor living without air-conditioning is next to impossible, and they become a sort of indoor-outdoor living room. Modern ones often feature shade cloth and trellising to support climbing plants.

A true shadehouse is generally a greenhouselike structure, but it's covered in shade cloth and is designed to cover an outdoor garden space. The shade cloth filters the sun and heat while it lets rain in. It can incorporate cooling mist systems and automated watering, creating what is essentially an artificial backyard jungle—and it will even protect plants from light frost in winter. It is popular in hot, humid climates and may cover much of the yard.

Pruning Trees and Shrubs

Barbara W. Ellis

Pruning is an art and a science, but it need not be a mystery. The skillful pruner is one who combines a solid understanding of the basics with an eagerness to learn the specific needs of the plants in his or her care and the courage to make the first cut. With these skills, you can regard pruning with the same fondness ascribed to most other jobs in the garden. Moreover, pruning can be a source of learning and accomplishment.

It's a good idea to become familiar with the parts of a tree before you prune.

1. *lateral bud*
2. *terminal bud*
3. *primary branch*
4. *secondary branch*
5. *dropping branch*
6. *suckers*
7. *girdling root*
8. *tap root*
9. *lateral root*
10. *feeder roots*
11. *leader*
12. *twigs*
13. *water sprouts*
14. *bark detail*

Continued ➔

Pruning with a Purpose

Rare is the landscape plant that wouldn't benefit from some purposeful pruning now and again; some species seem to need it more than others. The trick is to recognize and respect the natural growth habit of the particular tree or shrub and prune with a goal that honors the plant's natural inclinations.

Pruning in general improves and promotes the health, vigor, productivity, safety, and appearance of a tree or shrub. You will want to prune a young tree to give it a favorable root-to-top ratio and to promote its structural soundness and appearance as it matures. You will want to remove dead, dying, or diseased wood, along with crossing or rubbing branches. As the tree grows, you will want to prune away water sprouts, suckers, or wood infested by insects that may appear.

If you find you want to prune a tree or shrub to force an unnatural shape, question that plant's appropriateness for the location—or the method of pruning. From flowerless, ball-shaped forsythias to dehorned sycamore trees, tragic examples everywhere prove that no amount of pruning can salvage a poor plant or site choice.

You may be tempted to prune a tree or shrub in order to keep it in bounds, a practice that should be used only on those plants—and by those gardeners—best suited for such discipline. As most plants will eventually attain the mature size appropriate for the conditions, try to make realistic choices when selecting plants. For example, if you have a small area that could be overrun by a large tree or shrub, you may want to consider the many dwarf and slow-growing landscape plants available today.

Another common but noble reason for pruning is to correct some kind of misshapenness or to rejuvenate a plant. The need for this is often created by crowding, mechanical mishaps, poor pruning in the past, or some form of neglect (benign or otherwise) usually attributed to the former resident of the property.

Another purpose for pruning is what might be called specialty pruning—things you might do after pruning has become a skill that you own completely. Topiary and espalier fall into this category.

Anatomy of a Tree

Knowing the various parts of a tree will be a great help not only when you prune but also in understanding how a tree grows. The tree has water sprouts, narrow crotch angles, suckers, and a broken branch that should be removed. The drooping branches near the base should also be removed. Also illustrated is the spreading root system of a well-anchored tree along with a girdling root around the base of the trunk that could eventually strangle the tree.

The phloem layer just under the bark carries food down from the leaves. Just beneath is the all-important cambium layer, a one-cell-thick layer that gives rise to all new wood. These layers, which are close to the surface, are easily damaged by girdling roots as well as lawn mowers. Inside the cambium is the sapwood, which carries water and nutrients to the foliage, and the heartwood, which is inactive sapwood that provides structural support.

PRUNING PHYSIOLOGY

The reluctant pruner should bear in mind that pruning almost always is an invigorating process for the plant. Especially if the tree or shrub is pruned while dormant, topgrowth can be reduced while much of the plant's energy is still stored in the roots. When spring comes, the root-to-top ratio is favorable and the stored carbohydrates are more than adequate to support the rapid flush of growth on top. In fact, research has shown that young trees cut back at planting time tend to outgrow those that aren't.

In specific circumstances, pruning can be debilitating for the plant. If the tree or shrub is heavily pruned while actively growing, particularly after a rapid flush of growth, it loses tissue in which it has just invested a lot of energy, without getting any return from that foliage. Pruning can also be debilitating when it is done so late in the growing season that it brings on a flush of growth that gets damaged by the first fall frost.

Skillful pruners pay close attention to the season, the plant's condition, and its response to the weather. They are fully conscious of the annual rise and fall of sap and work according to that physiology. They avoid pruning during periods of active growth unless that's called for; they avoid spring pruning of tree species that are inclined to "bleed" sap heavily.

Ten Pruning Myths

1. All pruning should be done during the dormant season.
2. A tree can bleed to death if you prune it at the wrong time.
3. A large shade tree and an overhead utility line can usually coexist peacefully.
4. All large cuts should be treated with a wound dressing.
5. Pruning will keep a tree or shrub in bounds.
6. Pruning slows growth.
7. A good pruning job should be obvious.
8. Needle evergreens can be cut back hard, just like deciduous plants.
9. Large limbs should be cut so that they are flush with the trunk.
10. Plant diseases cannot be spread through pruning tools.

Basic Techniques

Regardless of the type of pruning you are performing, you will be drawing from a repertoire of two basic cuts: thinning and heading.

THINNING

A thinning cut is one which follows the branch to be removed back to the branch where it originates. The cut is made at the branch collar, almost flush, but leaving the collar and never leaving a stub. A thinning cut encourages the remaining limbs to continue to grow naturally and in their normal direction. A thinning cut also opens up the plant, reducing wind, snow, or rain load, and allowing sunlight to reach the ground or the innermost branches. In the same manner, thinning can be used to open a view without removing the tree.

HEADING

A heading cut, on the other hand, is one that takes the branch back to a bud or a pair of buds, rather than to the next limb. When a tree or shrub is headed back, some of the newest growth is cut away. Heading removes terminal buds, causing the buds behind the cut to break and begin to grow. Where thinning opens up the plant, heading causes it to branch and become more dense.

Shearing is a form of heading often used on hedges and in topiary culture, as well as on millions of ball-shaped shrubs in yards nationwide. Heading is often used and abused where thinning is really what's called for. The topping and dehorning of large trees are extreme, and often unnecessary, forms of heading.

When to Prune

Dead, damaged, decayed, or infested wood can be removed almost any time. If disease is involved, be sure to disinfect your pruners before you move on to the next plant. (Isopropyl alcohol is a good disinfectant and it won't corrode your pruners.) In almost every case, damaged or diseased wood is removed with a thinning cut.

Suckers, water sprouts, and crossing, rubbing, or out-of-control branches also can be removed with a thinning cut almost any time. However, the job will be easiest when the plant is dormant and the leaves have fallen away, because you can then get a good look at the tree's structure.

The timing of almost all other pruning is determined by the season of flowering. Spring-flowering shrubs, such as forsythia (*Forsythia* spp.), quince (*Chaenomeles* spp.), and most rhododendrons and azaleas (*Rhododendron* spp.), should be pruned immediately after flowering. Other spring-blooming plants include viburnum (*Viburnum* spp.), daphne (*Daphne* spp.), pieris (*Pieris* spp.), and deutzia (*Deutzia* spp.). Don't procrastinate—next year's flower buds begin to form shortly after the flowers fade, and late pruning will remove them. The only dormant-season pruning appropriate for spring-blooming plants is rejuvenation, thinning, or the removal of dead, dying, diseased, or unruly wood. Head back a spring bloomer in fall or winter and you've lost your flowers for that year.

Summer-blooming plants usually form their flower buds on the current season's wood. Therefore, plants such as crape myrtle (*Lagerstroemia indica*), hibiscus (*Hibiscus* spp.), and abelia (*Abelia* spp.) can, and should, be pruned in the winter. Also included in this list are chaste-tree (*Vitex* spp.), butterfly bush (*Buddleia* spp.), blue-beard (*Caryopteris* spp.), hydrangea (*Hydrangea* spp.), and some species of rhododendron such as the late-blooming native azaleas *Rhododendron prunifolium* and *R. arborescens*.

Winter-bloomers such as some daphne species, winter jasmine (*jasminum nudiflorum*), and winter honeysuckle (*Lonicera fragrantissima*) can be treated essentially as spring-bloomers, and pruned after blooming.

Special recommendations for pruning young and mature shade trees, evergreens, shrubs, and hedges are given in the sections that follow.

Pruning and Training Young Trees

Get any young tree off to a good start with some judicious pruning at planting time. Use thinning cuts to eliminate dead, diseased, crossing, or rubbing branches, along with suckers, water sprouts, and branches with narrow crotch angles. Once these basic concerns are attended to, give some thought to the tree's intended purpose and devise a strategy to attain that goal. Will the tree be used for shade, to screen an unsightly view, or to frame or filter a pleasing one? Will it be expected to hold up one end of a hammock? Plan to prune accordingly.

The first five to seven years of a young tree's life will be its training period for a future as either an asset or a liability. Assuming that you removed all troublesome growth at planting time, make an appointment with the tree each winter to look for more of those same signs of trouble.

If the tree is to be walked under, consider removing the lowest limb or two after about the third or fourth year. Continue this annually until the lowest branches are at an appropriate height. This technique is called limbing up and, on a young tree, should be done gradually over several years. This is part of your tree's training; by leaving limbs and removing them gradually you allow them to contribute to the girth and taper of the trunk.

During this time, also give some attention to the scaffold branches, those growing directly from the trunk. Thin them to ensure that they are evenly spaced and not crowding one another. Also watch for narrow crotch angles and thin in favor of wider ones, which are structurally stronger. Feel free to remove the errant branch that heads for the roof of your house

Continued →

or threatens to ruin the natural silhouette of the tree. Also watch the central leader of your young tree and thin out any branches that compete directly with it.

After about the fifth year, consider thinning the crown to reduce loads from wind, snow, ice, or rain. If the plant is destined to become a large shade tree, you will eventually need to hire an arborist for this job. Remove no more than about one-third of the crown at a time.

If your tree has been planted to screen an unsightly view, retain its lower branches and prune it for fullness. To do this, use thinning cuts to attain a sound structural framework, and follow with judicious heading cuts to promote branching. The earlier you begin with this sort of training, the better the eventual results.

If you wish to have your tree filter rather than screen a view, thin it regularly without heading back the branches.

Pruning a Mature Tree

The ongoing training you provide your trees will determine their form and strength as they mature; at maturity, the form and structural strength of a tree, which is maintained by proper pruning, can be a life-and-death matter. Training a young sapling is serious business—just ask any nursery operator. Nursery owners know that uniformity and predictability are important factors in mass production and sales.

When to Use an Arborist

In caring for a mature tree, it is critical to recognize your limitations and know when and how to hire an arborist. Without appropriate climbing, safety, and technical skills, removing even one errant branch can be risky business for a home gardener. Entrust your mature trees to a professional arborist.

Following are some of the services provided by professional, accredited arborists.

- **Plant management.** A management program will ensure that your trees will be examined, and corrected or treated if necessary, on a regular basis. Fertilizing, soil aeration, and pest control are other routine services that might be provided under a management program.
- **Regular pruning.** Structural correction and thinning are regular pruning services offered by arborists.
- **Storm-proofing.** This includes thinning to reduce snow, rain, or wind load; removal of weak branches; and balancing the crown so that, should it fall, it would cause the lease human hazard or property damage.
- **Grounding.** For old and valuable trees, especially on a high spot, cables can be installed that will minimize the damage of a lightning strike.
- **Cabling and bracing.** This is for trees that are structurally weakened in some way. Like grounding, cabling and bracing is worth considering for mature trees considered to be extremely valuable.
- **Topping.** Consider replacing either your arborist or your tree if this is recommended. Topping is the removal of most of the crown of the tree and usually results in horrible disfigurement. It is considered a necessary evil, especially where mature trees and overhead utility lines coexist. Still, few trees are worth having once topping has been done; consider replacing the tree with something more compatible with the reality of the site.
- **Removal.** The ultimate pruning job. If the task calls for equipment that you don't already have or don't have the training for, such as a chain saw, consider hiring an arborist.

Choosing an Arborist

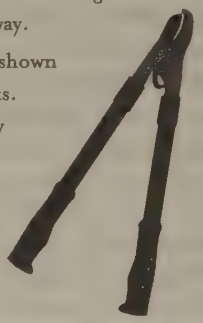
When shopping for an arborist, look around your own neighborhood, or a neighborhood with mature trees in it. You should be able to identify good work and sloppy work after some looking: The good work is practically invisible. Ferret out happy customers and ask for a referral.

If scouting around isn't for you, look up your nearest chapter of the International Society of Arboriculture in the telephone directory, and ask for a list of accredited arborists. Your nearest arboretum or botanical garden may also have such a list.

Be sure that your arborist is bonded or insured in some fashion. Don't be fooled by an impressive assortment of

Large Pruning Cuts—To Paint or Not?

The work of Alex Shigo and other leading tree-watchers has revealed that the use of tree wound dressing is, for the most part, unnecessary. Decay of the tissues related to the cut will occur with or without treatment. The function of the tree paint as a barrier for moisture has been refuted by the discovery that there is plenty of moisture that actually needs to escape at the wound site. Thus, wound dressing serves as a barrier in a nonproductive way.



Tree wound dressing also has been shown not to be a formidable barrier to insects. When there has been mechanical injury (such as an auto or mower mishap), or if the aesthetic condition of the tree is under close scrutiny, tree wound dressing can and should be used in a cosmetic manner. It usually makes everybody feel better.

chain saws and a truck with a chipper. Ask for accreditation, insurance, and a look at some of the individual's previous work. A professional will be happy to show you those things. Your investment of time and effort will be well worth it.

Pruning Shrubs

As with trees, your first concern when pruning shrubs should be to preserve structural stability and health. This includes removing crossed or rubbing branches, water sprouts, and suckers, along with dying, diseased, or infested wood. Such pruning can be done during any month of the year. A thinning cut is the cut to use.

The rest of the pruning work is done according to the season and the plant's physiology and bloom time. Most spring-blooming shrubs are pruned soon after they bloom, before they set flower buds for the following year. Winter-bloomers are handled in the same manner. Shrubs that bloom in summer usually can be pruned in the winter while they are dormant.

Pruning Objectives

There are several other reasons to prune shrubs beyond the basic structural concerns. Shrubs are pruned to reduce or limit their size, to keep them vigorous and flowering, and to thin them so that sunlight can penetrate the interior of the plant. For seriously overgrown plants, all of these processes are combined into one technique called rejuvenation.

LIMITING SIZE

One of the best ways to reduce or limit the size of a shrub is to use thinning cuts to prune away branches to the next side shoot, allowing the shoot to camouflage the cut. In this case, thinning will allow light to reach the interior of the plant and encourage new growth near the interior of the plant. Thinning works much better in the long run than shearing or heading back with pruners. Heading back new growth causes the shrub to have lots of dense growth around the tips, which shades the interior of the plant and makes it hollow. Many are the azaleas and forsythias that have been shorn rather than thinned and languish as round balls, hollow shells of their former selves. Prune with the understanding of how the plant would like to look.

OPENING UP

Many shrub species respond well to being opened up on a regular basis. This is a form of rejuvenation done while the plant is dormant. With this method, you remove two or three of the oldest (and usually least healthy) branches each year. Lilacs (*Syringa* spp.), forsythia (*Forsythia* spp.), abelia (*Abelia* spp.), heavenly bamboo (*Nandina domestica*), and Oregon grape (*Mahonia* spp.) do well with this approach. In addition to effectively reducing the height of the plant, keeping it in bounds, opening up also keeps the shrub well supplied with new wood. By rotating out old branches by cutting them back to the ground, you expose the innermost sections of the plant to sunlight, thus stimulating new, vigorous growth.

REJUVENATION

Frequently, new homeowners are faced with assortments of neglected, overgrown shrubs; occasionally, longtime homeowners are faced with a shrubby jungle if they don't stay on top of maintenance. Rejuvenation by thinning is effective on many such overgrown shrubs.

The first step is to decide whether the specimen is worth keeping, as your rejuvenation effort will require considerable commitment of time and energy. If a plant is horribly misshapen from competition with other plants, crowding, or mechanical mishaps, think twice and perhaps opt to remove it. If it's just an overgrown shrub with plenty of room and lots of appeal, determine if it can be rejuvenated and have at it.

As with the shrub where you removed old growth on a rotational basis, begin the first winter by removing—to the ground—two or three of the oldest limbs. Then come back the next year and do the same, being careful not to remove too much at one time, since full sun can be quite a shock to the innermost reaches of a plant. This process must be gradual. Eventually, the removal of the old growth will stimulate and make room for new growth and the plant will assume a new life.

Another form of rejuvenation involves the complete removal of the top of the plant during the dormant season. Although this can be done on some overgrown plants, the best results are with young, vigorous, annually-renewed specimens that bloom in the summer on new growth. Dwarf crape myrtles (*Lagerstroemia indica*), bluebeard (*Caryopteris* spp.), and abelia (*Abelia* spp.) are good candidates for this rather radical act of faith. Spring bloomers such as forsythia (*Forsythia* spp.) also can be rejuvenated this way, but, because the buds are already set, you will lose the spring bloom. Sometimes the sacrifice is worth getting the plant back under control.

One final method of rejuvenation pruning is a thinning process in which you transform an overgrown shrub into a comparably sized—but tamer—tree. Remove water sprouts and suckers; then begin limbing up and thinning back to a single or multiple trunk, selecting your scaffold branches as you go. This method works well for crape myrtle (*Lagerstroemia indica*), some viburnums (*Viburnum spp.*), and red buckeye (*Aesculus pavia*).

Pruning Hedges

Hedges can be short or tall, narrow or wide, formal or informal, depending on the plants you have chosen or inherited, the care required, and their natural growth habit.

With a new hedge, follow the same general strategy at planting time as described for other shrubs. The only pruning

Continued →

needed initially will be thinning to remove dead, diseased, or damaged branches.

Once the planting becomes established, pruning time and strategy will be determined by the hedge's level of formality. Prune an informal flowering hedge according to its flowering time—for example, prune forsythia for shape, if necessary—after flowering. Thin informal hedges to rejuvenate them during the dormant season. This helps keep the growth thick and lush and opens up the interior of the plant to encourage a steady supply of new shoots. Never shear an informal hedge.

Glossy abelia (*Abelia x grandiflora*), barberry (*Berberis* spp.), forsythia (*Forsythia* spp.), Chinese holly (*Ilex cornuta*), winter honeysuckle (*Lonicera fragrantissima*), and shrub roses (*Rosa* spp.) are all fine prospects for informal hedges. For a large informal hedge, consider hedge maple (*Acer campestre*) or Canada hemlock (*Tsuga canadensis*).

Treat a formal hedge much like a lawn, and trim or shear frequently throughout the growing season. As with grass, the best strategy is to cut as often as you can stand it, removing only a small bit of growth at a time. This frequent shearing is a form of heading back and encourages dense growth and the filling-in of holes. Among the plants that lend themselves to formal hedges are Japanese holly (*Ilex crenata*), yews (*Taxus* spp.), privet (*Ligustrum* spp.), and arborvitae (*Thuja* spp.).

Whether formal or informal, hedges should always be shaped so they are wider at the bottom than at the top, if only slightly. Failure to do this results in a hedge with bare ankles, then calves, knees, and so forth, because the top quickly shades the bottom and the plants become leggy. This is especially a problem with formal hedges. By making the top slightly narrower than the bottom, you allow sunlight to reach the bottom of your hedge and you are likely to have an enviable hedge . . . full to the ground.

Fern Marshall Bradley

You may not realize how versatile and useful vines can be in the home landscape. Train them up walls and trellises to provide shade or a privacy screen, or use them as groundcovers in difficult sites.

Use Natural Trellises

Vines make a great cover-up for some of those less-attractive features of a yard, such as a chain-link fence. They can also add an extra-special touch of beauty to the trees and shrubs in your landscape. Simply choose a shrub or tree in your yard, and plant a favorite climbing vine at its base. The vine will climb up and through the plant's branches. When you plant the vine, be careful not to damage the roots of the tree or shrub. Try these experts' suggestions for easy natural trellises.

Richard Hutton, the chairman of the board at the Conard-Pyle Company, a wholesale nursery in Pennsylvania, recommends growing a clematis (*Clematis* spp.) vine up a large yew tree (*Taxus* spp.). "Because of the dark green of the yew, it's a most effective display!" says Hutton. Roger Gossler, a co-owner of Gossler Farms Nursery, an Oregon nursery that specializes in magnolias, gets a similar effect by combining clematis with the dark green of magnolias (*Magnolia* spp.). He particularly likes to combine pink clematis flowers with the hot pink seedpods of *M. sieboldii*.

Karen Jennings, a senior vice president of Geo. W. Park Seed Company and Wayside Gardens in South Carolina, likes her clematis supported by viburnum (*Viburnum* spp.) bushes and dogwood (*Comus* spp.) trees. Dark blue clematis flowers particularly provide a lovely contrast when mixed with the white viburnum or dogwood blossoms.

North Carolina garden writer Peter Loewer admires pest-resistant Virginia creeper (*Parthenocissus quinquefolia*) growing in old apple trees or gnarled, dead trees. The vine's magnificent red fall color lights up leafless branches. "If it starts to choke a living tree or if you simply decide you don't want it, unhook the Virginia creeper and spread it on the ground where it makes an excellent groundcover," he says. Loewer also uses a clematis such as 'Madame Bruchard' with eastern white pine (*Pinus strobus*). The pine provides the base shade needed by clematis roots and shows off the clematis's purple-blue flowers. Try this clematis cultivar with camellias (*Camellia* spp.), too.

James W. Kelly, a New York plant taxonomist, finds climbing hydrangea (*Hydrangea anomala* subsp. *petiolaris*) particularly attractive in sugar maples (*Acer saccharum*). It is pest-free, has beautiful flowers, prefers light shade, and won't harm trees.

However, rampant vines such as wisteria (*Wisteria* spp.), bittersweet (*Celastrus* spp.), wild grape (*Vitis* spp.), and honeysuckle (*Lonicera* spp.) can kill trees. So can poison ivy (*Rhus radicans*). These vines reach high into the tree and spiral around branches, blocking light and reducing the tree's food supply. The best way to get rid of these overexuberant climbers is to cut them off at the roots. But don't rip down the vines; let them wither and fall off naturally. Otherwise the tree trunk will undergo a sudden change from being shaded to being exposed to the sun and may suffer sunscald damage.

Turn Old Vines into Trellises

For an unusual trellis, try training a vine over old vine prunings. If you have a brick garage or outbuilding, use mortar nails to create a pattern on one of its walls, suggests Bonnie Lee Appleton, Ph.D., an associate professor and extension horticulturist at Virginia Polytechnic Institute and State University. Garden centers carry special nails, called wall anchors or vine nails, that also work well. They have a strip of soft metal that can be bent around a vine's stem to hold it in place. After the nails are in place, weave prunings from grape or kiwi vines around them, then plant a flowering vine at the base of the trellis. As the flowering vine grows, train it to climb over the woody prunings. "The trellis looks nice even before a vine covers it," says Dr. Appleton.

You can also make a rustic-looking free-standing trellis by tying and weaving—and even stapling—vine prunings around two or more large, straight branches stuck in the ground. For lightweight vines like clematis (*Clematis* spp.), two branches set 1 foot deep in the ground should be sufficient. For heavy vines like wisteria (*Wisteria* spp.) or grape (*Vitis* spp.), add more straight branches for support, and set the branches 1½ to 2 feet deep or deeper if you have sandy soil.

Climbing Hydrangeas Start Slowly

Don't become discouraged if you plant a climbing hydrangea (*Hydrangea anomala* subsp. *petiolaris*) and it seems just to sit there for a couple of years. After a slow start, climbing hydrangea will "take off like a house afire, growing from 12 to 20 feet," says Appleton. "The wait is worth it. This vine has exfoliating bark, which makes it extremely pretty, even when naked." Make sure, though, Dr. Appleton warns, that you put climbing hydrangea where you intend to keep it, because this clinger will really latch on to whatever support you give it, and it won't let go easily.

Climbing hydrangea, which is hardy to Zone 4, likes a rich, moist but well-drained soil. It can tolerate semishade but blooms best in full sun, except in extremely hot climates.

Encourage Clingers to Cling

An occasional overhead watering will encourage a clinging vine, like climbing hydrangea (*Hydrangea anomala* subsp. *petiolaris*), smilax (*Smilax* spp.), coral vine (*Antigonon leptopus*), or trumpet vine (*Campsis radicans*), to cling by its roots, says Karen Jennings, a senior vice president of Geo. W. Park Seed Company and Wayside Gardens in South Carolina. "Once clingers are established, pinch off the tips just above the uppermost buds to make their growth denser, and prune out dead and weak wood before it blooms," says Jennings. "Cut back any over-long tendrils to two or three leaves."

Make Recycled Trellises

A tuteur is a fancy plant support for vines that's sometimes found in old French gardens. Tuteurs are elegant but expensive—unless you create your own. "You can make your own version of a tuteur. Just stick a long metal or plastic pipe in the ground and insert the framework of an umbrella into it," says North Carolina garden writer Peter Loewer. You can use any old umbrella that no longer has any fabric covering it. This umbrella trellis, above is particularly good for vines that grow by twining.

And if you're hooked up to a cable service, consider using that unneeded television antenna as a space-age-looking trellis. Stick it in the ground and train a flowering vine up and around it. Or try growing gourds or pole beans up it for an easy harvest.

Growing Vines

Jeff Cox

Versatility is the hallmark of vines. All scramble or climb, but that's where their similarity ends. You can grow vines for shade, for food, or for beauty of foliage, bloom, or fruit. Vines range from tough, woody grapes and wisterias to annuals like morning-glories and garden peas. Other favorite vines include climbing roses, clematis, Boston and English ivies, Virginia creeper, climbing hydrangea, bittersweet, and passionflowers.

You can find a vine for almost any kind of site—sun, shade, loam, or sand; boggy or dry; fertile or poor soil. You're better off matching the vine to the situation than trying to alter the environment to suit the specific plant. In general, most vines are tolerant of a wide range of cultural conditions. It is the

Continued ➔

exception, such as clematis (which requires cool soil around its roots), that has specialized requirements. Be sure to check the specific needs of any plant before adding it into your garden.

Landscaping with Vines

Vines' growing habits let you merge boundaries and soften harsh edges. Planting annual vines on fences, gates, an other structures quickly brings an established look to a young garden where the plants have yet to fill in. Use vines to define a garden room: Create green walls by covering fences, mark an entrance with a covered arbor, or provide overhead shade with a pergola.

From Seed to Vine

You can have beautiful vines for the cost of a seed packet. Try the following five beauties for color from spring until fall.

Black-eyed Susan vine (*Thunbergia alata*) produces 1- to 2-inch-wide orange, yellow, or white blooms with black eyes. Try planting them in hanging baskets, window boxes, and trellises.

Moonflower (*Ipomoea alba*) grows 8 to 10 feet long and has fragrant, white, night-blooming flowers. Soak seeds overnight or notch them with a knife or file to break through the seed coat and encourage germination.

Morning glories (*Ipomoea* spp.) will grow up to 25 feet long. They produce red, purple, pink, white, or blue flowers. Treat seeds as you would moonflower seeds for best germination.

Ornamental gourds (*Lagenaria siceraria*, *Cucurbita pepo* var. *ovifera*, and *Luffa aegyptiaca*) grown on a trellis will produce straight gourds in a variety of colors and sizes. Soak seeds overnight to promote germination.

Sweet pea (*Lathyrus odoratus*) bears fragrant pea-shaped flowers in every color but yellow in spring and early summer.

Vines soften and connect the hard edge between the structures and the plants in a garden. Plant Boston ivy or wisteria to climb up a wall of your home, and you'll link the house and garden. Vines also make the house wall more attractive, provide seasonal interest (in our example, Boston ivy has fall color and berries, and wisteria has early-summer bloom), and if planted on the south side of the house, the vines will help cool it.

Plant vines to screen unsightly walls or views. A planting of wintercreeper will make an ugly concrete wall into a feature rather than an eyesore. A chain-link fence can become an asset if you cover it with trumpet vine (*Campsis radicans*) with its showers of brilliant red-orange blooms in midsummer.

Versatile vines have many other uses as well. Clematis or other vines planted next to lampposts and pillars add interest to any garden. Make the most of a small garden or terrace by "growing up." Grow vines over railings and along windows and door frames to create a magical hideaway. Annual vines can be grown in window boxes and are useful on terraces. Morning-glories (*Ipomoea* spp.), scarlet runner beans (*Phaseolus coccineus*), and black-eyed Susan vines (*Thunbergia alata*) are good window-box choices. And don't forget attractive vines with edible parts such as cucumbers, pole beans, and peas.

Pruning and Training Vines

Pruning is your opportunity to train and control a vine. Look hard at the plant before cutting. The first step in any pruning operation is removal of dead, damaged, and diseased wood. Always use a sharp tool—a hand pruner, lopper, or saw—and make the cut just above a live bud or nearly flush with the stem. Only after "cleaning up" the plant should you start working on the live wood.

Prune live wood after the vine has finished blooming for the season. This means you'll prune spring bloomers in early summer, summer bloomers in early fall, and fall bloomers in winter or early spring. Remove dead wood anytime. Shape and control annuals by pinching early in the season. Pruning depends on the growth habit of the plant. Clinging vines like English ivy (*Hedera helix*), wintercreeper (*Euonymus fortunei*), and Virginia creeper (*Parthenocisms quinquefolia*) merely need trimming to keep them in bounds. Other vines like wisteria, clematis, and grapes will need annual pruning.

Vines the Low-Maintenance Way

If you'd like to spruce up your landscape in a hurry, try planting vines. Whether you want an easy-to-erect privacy screen, a simple way to hide a landscape eyesore, or just a quick burst of color, vines offer easy solutions to a host of landscaping challenges. Not only are they easy to grow, but their vigorous spreading nature also means they'll provide spectacular effects with little help from you. All they need is the right site and something to climb up, cling to, or scramble over. For an especially effective display—without any extra work—plant vines that offer colorful flowers, fruits, or bright leaves for autumn interest.

This section will help you choose easy-care, pest-free vines. You'll also learn easy ways to help them climb and thrive. Worried about having to build elaborate support structures for vines? Stop worrying! You'll find ideas for easy trellises, too.

Ask What Vines Can Do for You

Have you been struggling with landscape bugaboos like an unmowable lawn area, a garden the size of a postage stamp, or spots that are plagued with too much sun or shade? Forget about

costly landscape renovations; let vines solve site and exposure problems for you.

Add height to small gardens. Vines are a great way to add height in gardens large or small. They can also provide an alternative to expensive, slow-growing trees. They're great for providing an evergreen backdrop without adding too much shade. And their interesting leaf shadows and colorful blooms can add a whole new care-free dimension to small gardens. They can scale trellises, walls, or the trunks of existing trees to draw the eye up. Or let them drape over entryways and porches to create a sense of mystery.

Light up shady areas. To brighten a dark spot without trimming all your trees back, try vines with variegated foliage. Look for English ivy and wintercreeper with gold or white borders or streaks. Hardy kiwi (*Actinidia kolomikta*) has white and pink flushed leaves; variegated Japanese honeysuckle (*Lonicera Japonica* 'Aureoreticulata') has leaves marked with yellow. For best color, provide a spot with partial sun. Depend on the flowers of climbing hydrangea to brighten up very shady areas.

Replace lawn grass. If you have an area where grass won't grow or where you just don't want to have to mow, consider using a vine as a groundcover. English ivy works well in such a situation, as does winter-creeper and climbing hydrangea.

Shade a porch, pergola, or summerhouse. What if you need cool shade and privacy fast during the lazy days of summer, but you want sunshine for warmth in winter? No problem! Choose a vine that loses its leaves in winter, such as Dutchman's-pipe, hardy kiwi, or grapes. Or, choose an annual vine that will die back with the first hard frost, such as one of the morning glories.

Plant Vines to Hide Eyesores Fast

Is there an object in your landscape that you'd like to have disappear in a hurry? Vigorous vines can work magic when it comes to screening ugly architectural or landscape features quickly and painlessly. So to put your eyesore out of sight and out of mind, choose the vine vanishing act you like best.

Cover a chain-link fence. If your backyard is surrounded by a bare chain-link fence, why not dress it up with vines? Perennial vines, like trumpet honeysuckle, will hide it from view but may take a while to get established. As a "quick fix," plant fast-growing annual vines, such as hyacinth beans or morning glories, to add cover the first year.

Hide a hideous air conditioner. You can make an ugly air conditioner disappear with a screen of trelliswork and a mix of evergreen and annual vines. (Be sure to keep the trellis and vines 1 foot away from top discharge models; 6 feet away from side discharge ones.) The annuals will give you an almost instant screen and even some colorful flowers; the evergreens will give long-lasting cover.

Make a tree stump—or tree—disappear. Instead of paying to have a dead tree or tree stump removed, just make it disappear with vines. Hiding a tree stump is easy—just plant an evergreen trailing vine such as English ivy or wintercreeper around it. Within no time the stump will be history. To turn a dead tree into an attractive addition to the landscape, use it as a support for trumpet honeysuckle or wisteria.

Vines Thrive When the Site Is Right

Do a little site research before you plant if you want to grow vines that will make your landscape look marvelous. For the best results with the least work, choose vines that are adapted to the site and soil conditions in your garden. That way, your vines will have the conditions they need to thrive, and you won't spend any extra time improving or changing the site. Use the questions below to help you evaluate your site and narrow your hunt for the perfect vine.

What's your light like? The amount of light a site receives helps dictate which vines will grow best there. Morning glories and black-eyed Susan vines need a site with full sun, while silver lace vine requires only a half-day of sun. Boston ivy, grapes, trumpet vine, and Dutchman's-pipe are equally happy in sun or shade. (Flowering types will bloom less in shade, though.) And English ivy and climbing hydrangea prefer shady spots.

How does your soil stack up? Before you decide what vines to plant, find out if the soil on your site is rich or poor. Then select a vine that will thrive in the soil you have. That way, you won't have to fertilize and amend your soil to match the needs of a particular vine. Vines such as five-leaf akebia, porcelain vine, and grapes need fertile soil and will languish in poor sites. Others, such as hardy kiwi, grow too vigorously in rich soil and are best grown in infertile soil. Trumpet vine, English ivy, Boston ivy, and wintercreeper are not so particular and will take almost any soil type.

Does your dirt drain? Drainage is another soil characteristic to consider. Wisteria and some hybrid clematis must have good drainage to perform well; five-leaf akebia and hardy kiwi are more tolerant.

Where's your water? Most vines are drought-tolerant, but you may need to think about the moisture needs of a vine before choosing it for your site. For example, grapes need enough moisture during their growing season to form plump fruits. Clematis also needs large amounts of water. Use these vines if you have a moist, well-drained site, or make sure you have easy access to a water supply in case of drought.

Quick and Painless Pruning for Vines

Don't let the thought of pruning strike fear into your heart; perennial vines only look hard to prune. In fact, it only takes a few cuts once a year to maintain their shape, curb excess growth, and remove damaged or unhealthy shoots. One rule to

Continued →

remember when you're giving your vines their annual trim is to always cut back to a bud, a lateral branch, or the main trunk. Be careful not to leave stubs—they may die back and cause decay in the healthy branch.

PRUNE WHEN THE TIME IS RIGHT

For most flowering vines, the right time to trim is when you have the time. Unless you're doing drastic pruning, which is best done when plants are dormant, you can shape your plants in any season.

If time isn't a concern and you want the most flowers you can possibly get, arrange your pruning schedule to suit your vines. Prune all early spring flowering vines—including wisteria, Carolina jessamine, clematis, and trumpet honeysuckle—just after they finish blooming. If you prune before they bloom in early spring, you'll snip off flowers along with the branches.

Vines that flower in late spring to summer bloom on the current year's growth, so prune them in the spring. This early pruning will encourage new growth, which leads to more flowers. Examples are American bittersweet and silver lace vine.

Grapevines need yearly pruning in mid- to late winter before the sap rises. Merely cut each shoot of last year's growth back to one or two buds.

Give New Vines a Quick Trim

To get newly planted woody vines off to a good start, give them a haircut at planting time. Start by cutting the topgrowth back by half. This gives the roots a chance to develop sufficiently to support the top growth. When you prune, always make a slanted cut just above a bud. Trimming topgrowth stimulates side branches to grow more vigorously, so you'll get a sturdier framework to support future growth.

Restyle an Old Vine

It takes drastic action to rejuvenate and reshape an old or neglected vine, but it doesn't have to take lots of effort. Simply spread the process out over three or more years.

Year one. Don't do any pruning in the first year. Instead, observe your vine carefully during the growing season and decide which parts should go. Remove dead, diseased, and overgrown branches. To make pruning easy, tie colored tape or string around branches you plan to remove. These markers make it easy to find unwanted branches when pruning season arrives.

Year two. Start the pruning portion of your renovation when the plant is dormant, in late winter or early spring. That way, it's easy to see what you're doing because there aren't any leaves—at least on deciduous vines. It's also easier on the vine since it isn't growing actively. Thin out a few of the oldest, toughest stems first by cutting them back to 6 to 12 inches above the ground. New shoots will sprout in spring; when they reach 6 to 12 inches long, prune the tips to encourage branching.

Year three. Prune again the following late winter or early spring. Remove a few more of the remaining unruly stems as you did in year two. You can continue renovation pruning into a fourth year or until you bring the vine back to the size and shape you want.

Pruning Mature Vines

You can do light pruning to shape a mature vine whenever you have the time. Snip back the straggly shoots that give your plant a messy look, and thin out any dead, broken, or diseased wood. If your vine needs lots of pruning, wait until it's dormant before tackling the task.

Easy Ways to Help Your Vines Climb

Before you invest time and money constructing elaborate trellises and arbors, look around your yard. Plants already growing in your yard can make perfect vine supports. You can also use inexpensive pipes—either metal or PVC—along with a variety of found materials to make great-looking, easy-to-build trellises.

For example, interlace a framework of pipe with saplings, or rope it together with twine or vines. (You may need to tuck the vines in and out a bit as they grow to get the desired effect.)

Train up a tree. Let's face it, there are ways to support vines that are as easy as pie. Just look around when you drive in the country and you'll see vines scrambling happily up tree trunks all over the place. Why not give it a try at home? Just plant a climber at the base of a favorite tree, give it some strings or a temporary trellis to help it get up to the lowest branches, and sit back and watch it go. Some good examples would be clematis trained up a fruit tree, or climbing hydrangea in an oak. Or let lightweight trailing vines, such as black-eyed Susan vine or clematis, drape themselves over shrubs in your garden or meander their way among your perennials.

Stick with annual vines or well-mannered perennials if you try this technique. Evergreen vines, like English ivy, and extremely vigorous growers, like trumpet vine, can smother plants they cover.

Make a sapling tent. You'll need about 20 saplings, bamboo poles, or extra-long tomato stakes. Lash pairs together at the top. Add a "ridge pole" on top and lash it in place. Then tie crosspieces in place down the sides, parallel to the ridge pole, to add stability and help the vines climb. Have someone help you stand the tent up, then spread the legs, push them into the soil, and plant your vines at the base.

Make a teepee. For a vertical accent in a border or bed, you can make very attractive trellises or teepee-like supports from slender saplings or tree limbs. Cut them in 3- to 6-foot lengths and lash them together with mature grapevine cuttings or raffia (a fiber made from palm trees you'll find at your local hobby shop). You can make them as tall as you like and just plant vines at the base of the limbs.

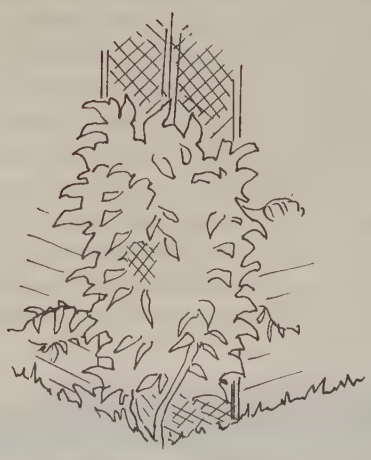
TREE

SAPLING TENT

TEE PEE

PVC PIPE

STRING



TRELLIS - CORNER

Continued ➔

Put together some pipes. You can make strong supports for heavy vines from metal or PVC pipes, which are available from hardware stores. Use 1-inch-diameter pipes or larger. An advantage of PVC pipe is that it can be easily cut to the length you want, fitted together with elbows and other joints, and glued together.

Adapt a trellis. When you want to cover a specific eyesore like a downspout, a standard flat trellis may not do the job. To make it hide more than one side, simply take two strips of cedar trellis as long as the downspout is high, nail them together at right angles, then butt them against the wall to which the downspout is attached. This way, you can cover a downspout with a vine without actually having it climb directly on it.

String up an annual. Slender twining annual vines, such as morning-glories and black-eyed Susan vines (*Thunbergia alata*), can be trained on sturdy twine as their sole support. Or give them some twine so they can work their way up to an awning or a piece of latticework. Just put a stake in the ground and attach the twine to it, then attach the other end of the twine to the farthest point you want the vine to reach.

Grow Your Own Awning

You can easily turn your hot, sunny porch into a cool retreat. All you need is a vigorous vine. Salvage an old awning frame, or attach a metal bar to your porch. Cover the framework with chicken wire and train a Boston ivy (*Parthenocissus tricuspidata*) or Dutchman's-pipe (*Aristolochia durior*) up it to create a beautiful, shady nook. Or use a silver lace vine (*Polygonum aubertii*) and watch your framework vanish in a froth of foliage and blossoms.

Create a Quick Wildlife Garden

Vines make a perfect centerpiece for a garden designed to attract birds, butterflies, and other wildlife. Hummingbirds are drawn to colorful blooming vines with tubular flowers. They're especially fond of the color red, so they adore cypress vine (*Ipomoea quamoclit*) and trumpet honeysuckle (*Lonicera sempervirens*). They also favor orange trumpet vine (*Campsis radicans*).

For attracting butterflies, try planting cypress vine, sweet peas (*Lathyrus latifolius*), wisteria, or Japanese honeysuckle (*Lonicera japonica*). Plant wild passionflower (*Passiflora incamata*), too, since it's a food plant for the caterpillar of the Gulf Fritillary. You'll see quite a show as the adult butterfly lays its eggs and caterpillars hatch out. You can expect some munched leaves, but it's a small price to pay for a front row seat at a butterfly drama.

The Benefits of Vertical Gardening

Barbara Pleasant

Good soil and healthy plants form the foundation for a successful garden, but where do you go from there? Most vegetables and flowers stay close to the ground, so trellised vines are unique in their ability to add a vertical dimension to any outdoor scene. In the vegetable garden, growing plants up rather than out pays off by increasing yields and improving plant health. Trellised pole beans, for example, typically produce 40 percent more beans per square foot than bush beans, and tomatoes must be trellised to prevent problems with diseases. With cucumbers and other small-fruited cucurbits, a trellis often coaxes plants to produce more leaves, which in turn gather more energy from the sun, resulting in larger, higher-quality crops.

As landscaping devices, trellises offer an easy way to block out unwanted views, create beautiful focal points, and enhance privacy. You can use trellised vines to create living walls for a lush, private retreat, or locate them so they will throw a curtain of shade over a hot spot on your patio, or give your deck plants much-needed relief from intense summer sun. But the best part of working with trellised flowers is the plants. From fragrant sweet peas to long-limbed miniature roses, flowers that reach for the sky always get plenty of attention.

Taking care of plants at eye level rather than in a bed is a bit easier for most gardeners, but you'll probably see fewer problems in the first place. Trellised plants dry off quickly after rain, which reduces their risk of leaf-spot diseases. Controlling insect pests is simple because you can see unwanted visitors as soon they appear, and early intervention is the second best way to limit insect damage—right after prevention. Even your body benefits from vertical gardening, since you can tend, pick, and enjoy your plants with much less bending over.

Getting Started

Once you decide you want to grow a plant that is willing to scramble up a trellis, there are several types of structures to consider, from lightweight string trellises to wood or wire panels to triangular teepees. But before you start building, look around and see what you already have.

- An ordinary chain-link fence makes a fantastic trellis for most vining vegetables and flowering vines.
- You can easily add a wire trellis to the back side of a wood fence that will provide easy moorings for curling tendrils or twisting stems.
- Deck railings can be put to work as a ready-made trellis for container-grown vines, and you can transform entryways by using porch posts—or your front-step handrail—to support a well-behaved vine.
- Get double duty from wood posts that are already serving another purpose, whether they are holding up a mailbox or birdhouse or are part of an existing fence. Add a few nails and screws, attach some strings or wire,

and create an instant pillar for edible or ornamental vines.

Choosing the Right Site

Before you decide where to place a new trellis—or how you will make use of a structure you already have—consider the site from the vine's point of view. Of course you want to pick a spot where a trellis will look good or block your view of an eyesore next door, but you should make sure your plants will grow well in their new home, too. Begin by digging an exploratory hole. You can amend poor soil to improve its fertility, but make sure the soil can be dug deeply enough to accommodate new posts that may need to be set in place. If you encounter a buried boulder, you will need to look for an alternate site. Underground utilities also may restrict where you can dig deep holes for posts.

TRACKING SUN AND SHADE

Sun exposure will affect your choice of sites, too. The sun rises in the east and sets in the west, and in the Northern Hemisphere, it always arcs a little to the south as it moves across the sky. The sun's angle matters little to low-growing plants, but it causes tall plants and trellises to cast shadows. To minimize the shade created by trellised plants, try to locate trellises on a north-south axis when growing plants that need abundant sun. This means that one side will face east while the other faces west. The west (afternoon) side will get more intense sun than the east (morning) side, but the difference will be less than it would be if the trellis faced north-south.

If you want to use a trellised vine to create shade, this will happen naturally if you locate a trellis on the south or west side of a hot spot in your landscape, or if you build an overhead arbor. For example, if your goal is to be able to sip tea on your deck on a summer afternoon while hummingbirds dart in and out of a lush screen of scarlet runner beans, locate the trellis on the west side of your favorite sitting spot, because intense afternoon sun always comes from the west.

You can take the confusion out of studying a site's exposure by pounding a wood stake into the ground and watching it for a few days, making mental note of where its shadows fall. Don't worry about the shade that is created at the base of a trellis, because most vines thrive when they have their roots shaded and their heads in the sun.

PLAN FOR EASY REACH

Whether you are planning to support cucumbers or a clematis, you'll also need to position the trellis so you can get to the plant for watering, pruning, and harvesting. It is usually best to allow vines to run no higher than you can reach. Choose vines that fit the space you have to offer and your notions of reasonable maintenance, and keep in mind that a vine capable of growing 10 feet tall does not necessarily require a 10-foot trellis. Once vines reach the top of their support structure, they usually turn back toward the ground, creating a cascade of foliage, flowers, and fruit.

Sizing Up Structures

The projects in this chapter provide an array of trellising options, including tied-together teepees, versatile wire panels, wood pillars and trellises, and simple techniques for using plants to support other plants. Most are quite easy and inexpensive to build or make and require little or no carpentry experience. If you can hammer a nail or install a screw, you can make these projects.

Regardless of size, the sturdiness of any trellis depends on how well it is anchored. In some situations, you may want to set a post as securely as possible, which will require anchoring it in concrete. Concrete is messy but not especially difficult to handle. Still, before you decide that concrete is needed, consider simpler solutions.

Some trellises need no posts at all. The pyramid shape of teepee trellises often makes them self-anchoring. With trellises that do depend on buried posts to hold them upright, keeping posts as close to each other as possible can enhance the structure's sturdiness. Post size affects sturdiness, too. Stout posts can bear more weight than narrow ones, but they are heavier to handle and more troublesome to move. Posts only 2 inches square, installed 18 inches deep and 4 feet apart, do a good job of supporting tomatoes, peas, and beans in the vegetable garden, and they are easily moved by wiggling them a bit before pulling them up. Moderately heavy, long-lived plants such as climbing roses and clematis will be better served with a trellis that's attached to sturdier 2 x 4-inch posts. Permanent landscape structures call for 4 x 4 or larger posts.

SAFE AND STURDY POSTS

When selecting posts for your garden trellises, do not use pressure-treated lumber or wood treated with creosote if edible plants or herbs will be grown nearby. Whenever possible, use weather-resistant wood such as cedar, redwood, or locust as your first choice. Chemicals leaching from pressure-treated or creosote-coated wood can contaminate the soil. Several of the hundreds of chemicals in creosote are known carcinogens that can leach into the soil and be taken up by plants. Similar problems exist with the chemicals that have been used for the last 20 years to make treated wood posts more resistant to rot and termites, so grow only ornamental plants on posts made of treated wood.

Once you've taken stock of the trellising potential of structures that you already have, you can start having fun with vines and add to your collection of supportive plant structures. You should have no trouble finding just the right vine for any

Continued →

spot in your yard. Study what various sites have to offer because vines differ in their needs for sun, moisture, and the sturdiness of their support.

GUY WIRES

If a trellis is not as sturdy as you think it should be, you often can fix the problem by installing guy wires attached to nearby stakes, in much the same way that camping tents are secured in place. Two guy wires that pull on a trellis post from opposite directions work better than one, especially when the stakes are installed at angles that are diagonal from the trellis itself. Install the stakes at an angle, with their tops tilted away from the trellis. You also can use guy wires to attach a trellis to a nearby structure such as a building or fence.

Guy wires need not be actual wires at all. You can use whatever you have on hand to tie the trellis to stakes, including string, twine, or hemp cord. The main disadvantage of using stakes and guy wires is that they are easy to trip over, but this is less likely to happen if you paint them a noticeable color. Tying a few colorful ribbons to guy wires also makes them easy to see.

Matching Plants with Trellises

Posts serve as a trellis's legs, but most trellises also have a body made of wood, string, wire, or some type of fencing. The projects in this chapter show how you can use several versatile, inexpensive trellising materials, but there are loads of other ingenious possibilities. Creative gardeners often fashion unique trellises from flexible copper tubing or bent twigs and even tie together plastic six-pack holders to support their peas.

You can use whatever suits your taste and the needs of the plants you decide to grow. Vines are never snobbish about the support they receive as long as it matches the "growing equipment" they use to twine from point A to point B. These ingenious plant structures may be curling tendrils, curving stems, or sticky rootlets.

Curling tendrils reach out and wrap around whatever is available: Wire, string, branches, and woven-wire fencing all are fair game. Tendril-producing plants, such as peas and cucumbers, also wrap tendrils around their own leaves and stems. Young plants may need a little guidance to find their trellis, but once they get growing, they know what to do. Plants that produce curling tendrils often do best with a wire or mesh trellis.

Twining stems spiral around their support, and twining species vary in whether they twine clockwise or counterclockwise. Twining vines like pole beans and morning glory grow best when supported by poles, taut cords, or other trellising materials that resemble tree limbs or upright plants. Teepee trellises are ideal, and with a little encouragement, twining plants will cover a chain-link, wire-mesh, or lattice fence. When they run out of trellis, twining plants will twist around themselves.

Tethered vines, such as tomatoes and climbing roses, have no way to attach themselves to a support structure, so they must be fastened to their trellis. String or wire can damage the stems, so it is best to use strips of soft, stretchy cloth or discarded panty hose to tie them in place. You also can use green, plastic-coated wire twist ties. In addition, you often can train some stems manually by weaving them between the slats of a sturdy wooden trellis. Choose a solid, stationary trellis that does not move when pushed by strong wind.

Clinging vines, such as Virginia creeper, Boston ivy, and English ivy, have special holdfast roots that grow from the stems and attach themselves to surfaces (including tree trunks and wood, siding, or brick walls). The holdfast roots and the vines' foliage retain moisture, which can damage buildings. These vines should be watched closely and pruned as needed to control their spread. Although popular and beautiful, English ivy becomes aggressive when it is abandoned by the

gardener who planted it. It is easiest to control when grown in containers.

BEWARE OF INVASIVE VINES

When vines are perfectly suited to their site and soil, some reseed so successfully that they become weedy pests. A prime example is morning glory, which seldom causes problems in the North, but can become so weedy in warmer climates that it is listed as a noxious weed in Arkansas and Arizona. And, even though it is a native plant, love-in-a-puff (*Cardiospermum*) is on the noxious weed lists of six southern states.

If you want to grow a vine with a questionable reputation, start with a small planting, and locate the trellis near a walkway, driveway, or other paved surface. Or, place it where you can mow around it on all sides. Unwanted seeds can't sprout in concrete, and those that sprout in mowed grass can quickly be clipped into submission.

AVOID THESE UNSOCIAL CLIMBERS

Nicknamed "unsocial climbers" by botanists, a number of once-popular perennial vines have proven so invasive that they should not be planted at all. Even though you may be able to control the behavior of one of these vines in your yard, you cannot guess where a bird may drop a seed or what will become of the vine if you move away. Fortunately, there are plenty of safe native plants to take the place of these exotic invaders. Vines to avoid planting include:

- Climbing euonymus (*Euonymus fortunei*)
- English ivy (*Hedera helix*)
- Japanese honeysuckle (*Lonicera japonica*)
- Oriental bittersweet (*Celastrus orbiculatus*)
- Porcelain berry (*Ampelopsis brevipedunculata*)

List of Climbing Plants for Shade

Larry Hodgson

Climbing plants (also known as vines, climbers, lianas, and so on; the words are pretty much interchangeable) are curious plants. Almost all other land-dwelling plants use their own internal structure (mostly a cell component called lignin) to hoist themselves upward on their own through solid, tough stems, branches, and trunks. Even annuals and perennials use lignin to solidify their stems, but woody plants are masters of the art. Wood is full of lignin and that is why

22 Garden-Worthy Vines

Seven Vines for the Vegetable Garden

Plant Name	How It Climbs	Description	Ideal Trellis
Cucumber (*Cucumis sativus*)	Curling tendrils	Fast and productive, cucumbers often need to be tied to their trellis because cucumber tendrils are sparse and weak.	Try a 3-foot-tall teepee or a diagonal trellis made with wire mesh or plastic hardware cloth.
Lima Bean (*Phaseolus lunatus*)	Twining stems	Heat tolerant and pest resistant, heirloom varieties often run 10 feet and produce beans with maroon markings. Limas grow best where summers are long and warm.	Provide a teepee-type trellis 8 feet tall or grow on a wire-mesh fence.
Malabar Spinach (*Basella rubra*)	Twining stems	A vigorous grower in hot weather, this plant's glossy young leaves taste like Swiss chard when cooked. Unpruned vines grow to 15 feet and often reseed in warm climates.	Grow three plants on a single sturdy teepee or pillar.
Pea (*Pisum sativum*)	Curling tendrils	Short varieties of snow, shell, or snap peas grow to only 18 inches, but taller ones reach 5 to 6 feet. Plant first thing in spring because peas love cool weather.	A light net or string trellis is sufficient for peas.
Pole Bean (*Phaseolus vulgaris*)	Twining stems	Easy to grow, with a huge selection of varieties. Some have purple or yellow pods, and vine length varies with variety, from 4 to 10 feet.	Provide a teepee-type trellis 4 to 8 feet tall, or grow pole beans on a wire-mesh fence.
Scarlet Runner Bean (*Phaseolus coccineus*)	Twining stems	Young pods are edible and so are the flowers. Vines run 6 to 8 feet and grow best where summers are not extremely hot.	Adapts to many types of trellises, from teepees to rustic twig fences to old stumps.
Yard-Long Bean (*Vigna unguiculata*)	Twining stems	Vigorous plants grow fast in hot weather, often growing to 10 feet. Harvest the beans when they are less than 18 inches long for best flavor	A pair of tall, sturdy teepees connected at the top.

22 Garden-Worthy Vines (Continued)

Nine Annual Flowering Vines

Asarina (*Asarina scandens*)	Twining stems	Dainty, well-behaved vine usually grows to 6 feet, laden with jewel-toned snapdragon-like flowers. Grows best where summers are not extremely hot.	Choose an attractive wood, wire, or string trellis. Can be grown in containers.
Black-Eyed Susan Vine (*Thunbergia alata*)	Twining stems	In addition to the common yellow varieties, there are others that bloom white and coral pink. Vines run to 8 feet and can be grown in containers.	Use wire or sturdy string to train up a mailbox post or other pillar; excellent cover for chain-link fence.
Cup and Saucer Vine (*Cobaea scandens*)	Curling tendrils	A robust grower with stems to 20 feet long, this vine makes a good shade screen where summers are quite warm. Flowers emerge greenish white and ripen to purple.	A sturdy wood or wire trellis is required because vines become lush and heavy by late summer.
Gourd (*Lagenaria* or *Cucurbita* species)	Twining stems and tendrils	Small-fruited egg or spoon gourds mature fast enough to be grown in any climate, and the vines grow to only 10 feet. Large-fruited varieties grow to twice that size.	Grow small-fruited varieties on a pillar, diagonal, or teepee trellis. Large-fruited varieties become very heavy and need a sturdy support made of wood or wire.
Hyacinth Bean (*Dolichos lablab*)	Twining stems	Sometimes called ornamental butter bean, this plant's 10- to 20-foot-long violet stems produce lavender flowers, followed by glossy purple seedpods.	One or two plants can be supported by a string trellis, but a larger planting needs sturdy wood or wire support.
Morning Glory (*Ipomoea* species and hybrids)	Twining stems	Easy to grow and widely adaptable, morning glories come in numerous colors. Vines run 10 feet or more. Often invasive in warm climates.	Grow on a sturdy wire trellis, pillar, teepee, sunflower stalks, or a chain-link fence.
Purple Bells (*Rhodochiton atrosanguineum*)	Twining stems	Tender perennial grown as an annual, this vine likes rich soil in partial shade. Grows to 10 feet and produces exotic two-toned purple flowers.	Choose an attractive wood trellis. Can be grown in containers.
Spanish Flag (*Mina lobata*)	Twining stems	Sprays of tubular blossoms open red and ripen to yellow. Vines run to 15 feet, and seeds germinate best when soaked for a day or two before planting.	Grow on a sturdy wire trellis, teepee, or wood pillar.
Sweet Pea (*Lathyrus odoratus*)	Curling tendrils	Beautiful and often fragrant, most sweet peas climb to about 5 feet. Grow in cool weather, and nick the seeds to help them germinate faster.	A string or net trellis is sufficient for sweet peas. Can be grown in containes.

Six Long-Lived Perennial Vines

Clematis (*Clematis* hybrids)	Twining stems and tendrils	Gorgeous flowers in a wide range of colors with attractive green foliage on 10-foot vines. Adapted in Zones 4 to 9, pruning times vary with variety.	Can be trained to grow into small shrubs or trees or on a wood or wire support.
Climbing Rose (*Rosa* hybrids)	Curved thorns, requires tying	Stiff arching canes bloom heavily in late spring, and often repeat bloom. Adapted in Zones 4 to 9, canes must be tied or wired to a stiff trellis.	Choose an attractive wood trellis to accompany the classic beauty of a climbing rose.
Cross Vine (*Bignonia capreolata*)	Curling tendrils	Improved varieties of this native evergreen vine bear orange or red flowers that attract hummingbirds. Vines grow to 20 feet in Zones 5 to 9.	Choose a sturdy wood or wire trellis that needs little maintenance since the plants are never fully dormant.
Grape (*Vitis* species)	Curling tendrils	Woody plants may live for decades. Adapted in Zones 4 to 9, grapes bear sweet fruit, and you can use the pruned branches for other projects.	Provide a very sturdy wood and wire trellis, or grow grapes over an arbor.
Hardy Kiwi (*Actinidia arguta*)	Twining stems	Large, woody plants become quite massive, mature female plants produce flavorful fruits. Adapted in Zones 4 to 9, hardy kiwis need periodic pruning.	Provide a very sturdy trellis constructed of wood and wire.
Passionflower (*Passiflora* hybrids)	Twining stems	Exotic blossoms followed by green egg-shaped fruits on 10-foot vines. Hardy in Zones 7 to 9, but can be grown as an annual farther north.	Best grown on a post, pillar, or stump or combined with annual vines on a larger trellis.

trees are able to grow so tall. Without lignin, they'd flop over like rubber. However, building a strong structure out of lignin is a slow process requiring a great deal of energy, and often the tallest plants of the forest are the slowest-growing ones.

Climbing plants, though, have little use for huge quantities of lignin: They've found a way around that constraint. They hook or wrap themselves around host plants that do produce abundant lignin and use their host's hard-won structure to reach for the sky. So climbing plants are essentially profiteers, almost parasites, taking advantage of other plants and giving them little if anything in return.

We ought to find the actions of climbing plants reprehensible; instead, we very much take advantage of their sneaky ways. Climbers, you see, are the ideal plants for "filling in" open spaces. They hoist themselves up walls and fences as readily as they do trees, and our gardens usually have lots of such barren spots to cover. So we plant them to cover up unwanted views and to add interest to otherwise dull structures: You can use them to cover up an old stump or even bring a dead tree back to life by letting vines cover it. In fact, we purposely add structures just for climbing plants to grow on: trellises, arbors, and pergolas. After all, what are they if not fast-and-easy supports for climbers?

As climbers reach ever upward, they don't take up a lot of space on the ground. Perennials and annuals need large flowerbeds, shrubs and conifers have spreading branches that just eat up space, and trees, with their thick trunks and massive root systems, are true space hogs. Climbers need only a small space—a single planting hole—to reach out in all directions . . . but uniquely vertically. If fact, you can usually cover an entire fence or wall with just one climber, using little horizontal space indeed. Where gardening space is rare, such as in small urban gardens, climbing plants allow you to have abundant greenery without losing virtually any usable space. So with climbers, you can have the patio, the swing set, the sandbox, and the pool . . . and still garden!

Born to Climb

Botanists believe climbers evolved from nonclimbing ancestors that "learned" a faster way to reach the sun. They began as tall but weak-stemmed plants that started to lean on their neighbors rather than put too much of their own energy into building a solid structure. Over time, they became so good at leaning they abandoned all other means of vertical growth. As generations passed, different climbers evolved different and often more effective means of taking advantage of their host. Here are the main ones.

Scandent climbers: These are also called clamberers; they are the least specialized climbers. They still essentially lean on their neighbors, but as their stems reach upward they manage to mingle with the branches of their host and thus gain extra support. They have no special structures to aid them in climbing, nor do they twist around their host. Where they find no host nearby to lean on, they usually contain enough lignin to grow as arching shrubs. In the garden, you'll have to either attach scandent climbers to their support or wind them through lattice or nearby branches to get them off the ground. Winter jasmine (*jasminum nudiflorum*) is a well-known scandent shrub.

Hook climbers: They're also fairly primitive and are also called clamberers. They don't twist or stick to their host, only lean and mingle like scandent climbers, but they have the added advantage of thorny stems that can hook on to their hosts. In the garden, they too usually have to be attached to their supports; otherwise they'll grow as tall, arching shrubs. The best-known clamberer is the climbing rose.

Weavers: Just a step up from scandent climbers, weavers mostly lean on their host but also undulate as they grow and thus manage to work themselves in and out among the branches they grow through. In the garden, they may still need some help from the gardener in getting started (you may have to attach them to their supports initially) but will usually weave their way in and out of a trellis or chain fence on their own once they get going. Without a support, they simply flop, not having enough lignin to hold themselves upright. Confederate jasmine (*Trachelospermum jasminoides*) is a weaver.

Twining climbers: Also called twiners, they don't just undulate; they twist around their host, with stems that grow in a spiral. Depending on the species, they may grow clockwise or counterclockwise. They are very efficient climbers—if you don't supply a support, they'll creep along the ground until they find one. They don't make good groundcovers, though, as they keep reaching up in search of a support, so they appear irregular. Often several branches will twist around each other and attempt to grow upright, usually flopping back down again, as they don't contain enough lignin to go very far. Morning glories (*Ipomoea* spp.) and wisterias are well-known twiners.

Root climbers: These are called rooters for short. Actually, they are officially called "adventitious root climbers," but "rooters" is so much easier to say. They produce specialized roots called holdfasts on the underside of the stem; these cling to bark, wood, brick, stone, and so on. Unlike other twiners, they are able to climb flat surfaces like stone walls without a trellis or grid. On the other hand, they won't climb up open fences (such as chain link): They seem to need broad surfaces on which to take root. Rooters usually make good groundcovers, as they hug the ground when they can find no support. The best-known rooter is English ivy (*Hedera helix*).

Clinging climbers: Also called clingers, these climbers have specialized appendages that attach them solidly to their host.

Continued ➔

The best known are tendrils, such as seen on grape vines: They are special growths that twist as they grow, wrapping around their support. Sometimes it is the leaf petiole that twists around objects, or the leaf tips. In general, tendrils can wrap around only fairly thin objects: They'll grow around string, wire, or thin branches but may need to be attached to heavier supports, such as thicker lattices and trellises.

The most specialized of the clingers are Virginia creeper and its relatives (*Parthenocissus* spp.). They bear adhesive disks at the tips of their tendrils: They'll wrap themselves around thin objects like other clingers but can also climb flat surfaces, like walls and trunks. Many clingers make good groundcovers where there are no nearby objects to cling.

Nature, of course, hates man's attempt to neatly package its species into convenient groupings, so not all plants stay in their assigned categories. Many climbers are not climbers all their lives, for example. English ivy and its relatives (*Hedera* spp.), for instance, are typically climbing plants in their youth but change into shrubs at maturity. That is, when an ivy has grown high enough up into the tree canopy to get the light it needs, it suddenly starts producing woody branches complete with larger, rounder leaves instead of climbing stems. It is only the woody form that flowers and fruits. Oddly, once an ivy matures, it will never again produce climbing stems, and even cuttings taken from mature growth will grow as shrubs, never as climbers.

Climbing hydrangea (*Hydrangea anomala* subsp. *petiolaris*) does just the opposite: It starts off as a shrub with solid woody branches and may grow that way for years. Then suddenly, for reasons unknown, it decides it is time to climb and sends out stems that stick to nearby surfaces. Still other climbers, winter jasmine for one, will start producing woodier branches if pruned regularly and will then happily live the rest of their life as a shrub. And who hasn't seen a wisteria changed, by harsh pruning, into a small tree?

Don't be stunned if your climber starts behaving in a very unvinelike fashion: Climbers are full of surprises!

Herbaceous or Woody?

Climbers can be either herbaceous or woody. Herbaceous climbers, like herbaceous perennials and annuals, die to the ground at the end of the season. Some die entirely (there are many annual climbers!); others resprout from underground roots the following season. Practically by definition, herbaceous climbers tend to be comparatively short: There is a limit to how much growth they can put on in a single season. Even so, some reach 20 feet (6 m) or more in just one season and are among the fastest-growing plants known.

Woody climbers have perennial stems that become tough and fibrous. Because they don't die to the ground each year, they can build on the previous year's growth and thus grow taller and taller over time. Some reach well above 50 feet (15 m) in height over the years. In general, woody climbers are slower-growing than herbaceous ones and may take years to reach their maximum height. Note that "woody" is used in the sense of permanent: Not all "woody climbers" produce stems covered with bark that look woody to the eye.

Of course, herbaceous and woody are terms most appropriate to temperate climates. Many tropical vines that grow as annuals in the North are actually long-lived tropical vines in their native land, with stems that grow taller from year to year. Some morning glories (*Ipomoea* spp. and *Convolvulus* spp.), for example, are true annuals, but others are tropical climbers grown as annuals. And in extremely cold climates, many woody climbers will die to the ground most winters and sprout anew in spring, as if they were herbaceous.

For the most part, shade-tolerant vines are woody: In adapting to poor light, they found it simpler to grow slowly upward over time, putting on a bit more height each year. Starting from scratch each season takes lots of energy! In this section you'll find mostly woody climbers.

Shade and Climbers

Many of the climbers described in this chapter are equally well adapted to both sun and shade . . . and that's because of their unique growth cycle. They're adapted to germinating in deep shade where the competition for space is less intense. From there, they either slowly build up energy or ramble about, looking for a host to climb on. Even when they find support, they are still in shade, but climbers persevere, reaching up and up through the host's dense foliage until they finally begin to pierce its crown. In general, it is only when climbers reach full sun that they begin to bloom.

Most of the "shade-tolerant" climbers described here are therefore actually sun lovers who are just biding their time. They can grow for decades in very deep shade . . . as foliage plants. But many of them rarely bloom there. You'll notice that most of the plants described here are grown for their attractive growth habit and beautiful leaves rather than for their flowers.

Actinidia

Kiwi vine

Plant Profile

Actinidia: ac-ti-NID-ee-uh

Bloom Color: White

Bloom Time: Varies by species; see individual listings

Length of Bloom: 2 to 3 weeks

Height: Varies by species; see individual listings

Spread: 17 to 20 feet (5 to 6 m)

Garden Uses: Arbors and trellises, background, container planting, specimen plant, woodland garden; edible fruits

Light Preference: Full sun to shade

Soil Preference: Humus-rich, evenly moist, well-drained soil

Best Way to Propagate: Take cuttings in midsummer

USDA Plant Hardiness Zones: 3 to 8

The kiwis described here are not the subtropical ones that supply the large fuzzy fruits that are seen in supermarkets, but hardier species grown mostly for ornamental use. Most are vigorous woody vines that climb by twining about a support: If none is available, they'll grow as large, arching shrubs. The spring flowers are often numerous and usually creamy white and highly scented, although inevitably partially hidden by the foliage. Their main claim to fame is their beautifully variegated foliage. Small, sweet, grape-size fruits are produced on female plants in fall on mature specimens: They are not fuzzy like their large-fruited cousin and can be popped into the mouth and eaten as is.

GROWING TIPS

Kiwis prefer full sun for best blooming and fruiting, but are very ornamental in partial shade and grow well in shade, although often losing their leaf variegation. Any well-drained soil will do.

If you want to enjoy their fruit, make sure you plant both male and female plants (one male will pollinate eight or more females). Although plants may flower fairly young, it often takes 7 or 8 years before they manage to produce their first fruit.

Prune in early spring for better foliage; for fruit production, prune after flowers drop. These are vigorous, shrubby vines taking up considerable space in their youth until they begin to climb, and so are not for small gardens.

Warning: Be forewarned that cats adore *Actinidia kolomikta* and *A. polygama*, reacting to them as if they were catnip, and may not always content themselves with just rubbing against them: They'll often chew young *A. polygama* plants to death. Surround them with chicken-wire fencing for the first few years until they've grown enough that they are largely out of kitty's reach!

PROBLEMS AND SOLUTIONS

Cats chew stems and leaves. Few serious pests and diseases.

TOP PERFORMER

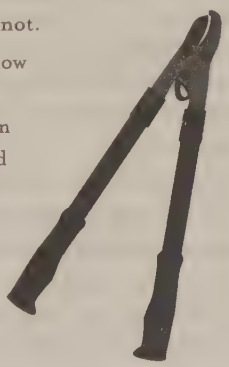
Actinidia kolomikta (variegated kiwi vine): A very dense-growing vine, especially appreciated for the coloration of its leaves. They are purple-tinged at first; then the lower half turns silvery pink in spring and eventually silvery white in summer. Not all the leaves are variegated, and the coloration is highly variable: Cooler growing conditions and sun to partial shade help bring out the color. Several cultivars with more highly variegated foliage, such as 'Arctic Beauty,' are available, though many of those grown mostly for their fruit are not very colorful. Blooms early, in late spring. Sweet yellow-green fruits are produced in fall. Height: 15 to 35 feet (4.5 to 10 m). Spread: 17 to 20 feet (5 to 6 m). USDA Plant Hardiness Zones 2 to 9.

MORE RECOMMENDED KIWI VINES

Actinidia arguta (hardy kiwi): This summer-blooming species has entirely green leaves and is grown more for its small but abundant fruit than as an ornamental, although its dense cover, dark green bristle-edged leaves, and scented white flowers make it very useful for decorative purposes as well. 'Issai' is a self-fruitful variety (it produces both male and female flowers on the same plant), ideal for smaller spaces. It is not a particularly prolific cultivar, though: There are dozens of better fruit producers. Height: 20 to 30 feet (6 to 9 m). Spread: 20 to 30 feet (6 to 9 m). USDA Plant Hardiness Zones 3 to 9.

Touchy-Feely Plants

Everyone realizes plants react to light, but did you know they also have a sense of touch? Twining vines twist about at random until they make contact with a vertical support, then they wrap themselves tightly around it. Their "sense of touch" tells them whether they need to draw tight circles, such as around a cord or thin branch, or much larger ones, as around a thicker support. If they make contact with a horizontal branch, though, they don't tighten at all but continue to twist openly. It's as if they examine the object they touch and then decide whether it is worth wrapping around or not.



Rooting climbers likewise show their touchy-feely side: They produce no roots unless the stem is pressed against an object—and even then they produce their roots only on the side touching the object.

This response of plants to touch is called thigma-tropism, in case you just had to know.

Continued →

A. polygama (silver vine): This summer-blooming species is a decidedly less vigorous grower than the others and can easily be accommodated in a small space. It is grown especially for its green leaves with silvery white tips, although the small yellow-green fruits are edible. Beware: This species is especially subject to cat damage. Height: 5 to 15 feet (1.5 to 4.5 m). Spread: 8 feet (2.4 m). USDA Plant Hardiness Zones 4 to 9.

Akebia

Chocolate vine, akebia

Plant Profile

Akebia: ah-KEE-bee-uh

Bloom Color: Purple

Bloom Time: Early spring

Length of Bloom: 2 to 3 weeks

Height: 20 to 40 feet (6 to 12 m)

Spread: 20 to 40 (6 to 12 m)

Garden Uses: Arbors and trellises, groundcover, woodland garden; on slopes

Light Preference: Full sun to shade

Soil Preference: Humus-rich, moist, well-drained soil

Best Way to Propagate: Take cuttings in early to midsummer

USDA Plant Hardiness Zones: 4 to 10

This is a vigorous, dense, semi-evergreen, twining vine: Grown on a fence, it will create a perfect wall of green, and as a groundcover it makes a smooth carpet. The palmate leaves are curiously notched at the tips, as if a tiny bird had taken a bite out if each one. They attempt to be evergreen, turning purplish in fall and clinging to the plant until early winter, but are eventually frosted off below Zones 7 or 8. The hanging, cup-shaped flowers are deep purple, sometimes even nearly chocolate-colored (whence "chocolate vine") but have little impact in the garden: You have to be right up close to notice them. Curious sausage-like fleshy purple fruits are produced and are edible, but insipid. Hanging on until winter, they are much more visible than the flowers but rarely produced.

GROWING TIPS

Here is a nice "grow-anywhere" vine, adapting equally well from sun to shade (although partial shade to shade is preferable in hot-summer climates) and almost any soil except ones that are extremely dry or extremely wet. Its growth is rampant: Plant it at the base of its future support so it can grow straight up, or it will go wandering all over your yard looking for a host. It makes a superior groundcover about 6 to 12 inches (15 to 30 cm) tall for spots where there is nothing for it to climb on. As a groundcover it is often best established among tall trees—it climbs by twining and can't manage thick trunks.

Pruning is well accepted; indeed, it will die to the ground in colder climates and still reach a good 20 feet (6 m) the following spring. Many gardeners prefer to cut it back each year to prevent it from getting out of bounds: After all, if left alone it will readily leave its original fence or trellis and invade neighboring trees, especially in mild-winter areas. Major pruning is usually done in early spring (late fall in the North). Wayward or invasive branches can be cut off at any season.

The male and female flowers are borne together in clusters on the same plant. (Hint: The female flowers are larger and darker and borne at the base of the clump; males are smaller and found at the tip.) Where fruits are produced, fall-sown seed germinates readily the following spring, but usually chocolate vine is multiplied by softwood or semiripe cuttings.

PROBLEMS AND SOLUTIONS

Chocolate vine seems virtually immune to insects and disease but may die back severely in cold winters.

TOP PERFORMER

Akebia quinata (chocolate vine, fiveleaf akebia): This is by far the most common species, with very attractive, schefflera-like leaves with five leaflets. They are dark green above, bluish green below. This species has scented flowers, said to smell of vanilla or cinnamon. There are a few cultivars, among which is the outstanding 'Variegata,' with pale pink flowers and leaves marbled white. Height: 20 to 40 feet (6 to 12 m). Spread: 20 to 40 feet (6 to 12 m). USDA Plant Hardiness Zones 4 to 10.

MORE RECOMMENDED CHOCOLATE VINES

Akebia x *pentaphylla* (hybrid chocolate vine): This is a cross between *A. quinata* and *A. trifoliata*, looking much the same as *A. quinata*, with four or five leaflets (occasionally six or seven), but the leaves are paler green and the flowers likewise not as dark purple, with a much fainter scent. Height: 20 to 40 feet (6 to 12 m). Spread: 20 to 40 feet (6 to 12 m). USDA Plant Hardiness Zones 4 to 10.

A. trifoliata (threeleaf akebia): As the name suggests, it's easy to tell this akebia from the other species by its leaflets, borne only three per leaf. They are also different in color: emerald green. The distinctly paler purple flowers are scentless but produce the same purple sausage-shaped fruit as the other chocolate vines. This species is deciduous in all climates and, although no hardier in actual survival rate than the others (Zone 4), its branches are more cold-hardy so it makes a better choice for garden use in Zones 4 to 6 than the others. Height: 20 to 40 feet (6 to 12 m). Spread: 20 to 40 feet (6 to 12 m). USDA Plant Hardiness Zones 4 to 10.

Ampelopsis

Porcelain berry, ampelopsis

Plant Profile

Ampelopsis: am-pel-OP-sis

Bloom Color: Green

Bloom Time: Summer

Length of Bloom: 3 to 4 weeks

Height: Varies by species; see individual listings

Spread: Varies by species; see individual listings

Garden Uses: Arbors and trellises, container planting, groundcover, hanging baskets, houseplant, specimen plant, woodland garden

Light Preference: Full sun to shade

Soil Preference: Humus-rich, evenly moist, well-drained soil

Best Way to Propagate: Layer in summer

USDA Plant Hardiness Zones: Varies by species; see individual listings

The genus *Ampelopsis* is made up of about 25 species of climbing plants very much like grape plants, although with smaller berries. They climb vigorously by tendrils and readily ascend fairly thin supports like small branches and chain-link fence. The foliage varies in shape, but is usually deeply lobed and maplelike. The leaves are deciduous on most species but usually make up for that by turning brilliant fall colors. Although they are perhaps best seen as foliage plants (certainly their clusters of greenish flowers lack impact), their berries are also very attractive, changing color as they mature and often showing several colors in the same cluster.

GROWING TIPS

Like many woody climbers, porcelain berry usually starts off its life in shade and works its way upward into sun; thus it is readily adapted to almost any light condition, although it will bloom and fruit heavily only in partial shade or sun. It is likewise adapted to most soil conditions except soggy soil. Irrigation during times of drought is certainly appreciated.

Opposite each leaf is a tendril that readily twists around objects of modest size, allowing the plant to grow to great heights over time. The tendrils are not very efficient at wrapping around thick objects, though: Even latticework is a bit much for them. You'll often find you have to attach this plant to its support or weave its stems through fencing or trelliswork to allow it to climb. The stems also look quite elegant when allowed to cascade down from a support, such as from the roof of a pergola. Where no support is available, it makes a wonderful groundcover, spreading indefinitely because the branches self-layer wherever they touch the soil.

Pruning is mostly done to control wayward stems and can be done at any time of the year.

The most obvious way to multiply ampelopsis is by layering: Most produce dangling branches that can easily be fixed to the ground. Cuttings also work well, and seed-grown plants come fairly true to type.

PROBLEMS AND SOLUTIONS

Leaf diseases are frequent but rarely serious enough to need treating. Flea beetles and Japanese beetles are major annoyances: Spray with insecticidal soap to treat the former; handpick or spray the latter.

TOP PERFORMER

Ampelopsis brevipedunculata (porcelain berry, porcelain vine): A charming and elegant climber with dark green three- to five-lobed leaves that look much like maple leaves. The fruits are the most attractive element of this plant, changing color from green to turquoise-blue to purple as they mature, often with all three colors visible at the same time. They are shaded with a crackled effect much like porcelain (whence the common name). Height: 10 to 30 feet (3 to 9 m). Spread: 10 to 30 feet (3 to 9 m). USDA Plant Hardiness Zones 4 to 9.

MORE RECOMMENDED PORCELAIN BERRIES

Ampelopsis aconitifolia (monkshood vine): There are dozens of interesting species of *Ampelopsis*. This one has leaves much like those of monkshoods (*Aconitum* spp.): very deeply and elegantly lobed and dark, glossy green. They turn beautiful shades of orange, yellow, and red in fall. The small yellow-orange fruits are also attractive in fall. 'Chinese Lace' is a new cultivar with very lacy foliage. Height: 10 to 40 feet (3 to 12 m). Spread: 10 to 30 feet (3 to 9 m). USDA Plant Hardiness Zones 4 to 9.

A. brevipedunculata var. *maximowiczii* 'Elegans' (variegated porcelain berry): This gorgeous cultivar has deeply cut leaves that are highly mottled white and pink, and bright pink new shoots. It has often been used as a houseplant. It bears the same green, turquoise, and blue berries as the species. Height: 3 to 10 feet (1 to 3 m). Spread: 3 to 10 feet (1 to 3 m). USDA Plant Hardiness Zones 6 to 9.

Euonymus

Wintercreeper

Plant Profile

Euonymus: yew-ON-i-mus

Bloom Color: Greenish white; insignificant

Bloom Time: Summer

Continued ➔

Length of Bloom: 3 or more weeks

Height: 4 inches to 70 feet (10 cm to 21 m)

Spread: Indefinite

Garden Uses: Arbors and trellises, container planting, edging, groundcover, hedge, mass planting, mixed border, rock garden, wall covering

Light Preference: Full sun to shade

Soil Preference: Humus-rich, evenly moist, well-drained soil

Best Way to Propagate: Take cuttings in summer

USDA Plant Hardiness Zones: 4 or 5 to 10

Wintercreeper is truly a triple-purpose plant: It is abundantly used as a groundcover, makes a great small shrub, and will also climb beautifully. It's a beautiful foliage plant, with glossy, dark green, oval leaves, usually with a serrated edge, with paler veins and purplish in winter. Most cultivars commonly available are highly variegated in shades of white and yellow. The leaves are fully evergreen, making this plant attractive in all seasons and one of the hardiest evergreen climbers. The flowers are insignificant, but the fruits, which open whitish to reveal a bright orange-red interior, are very attractive.

GROWING TIPS

Wintercreeper is most adaptable when grown as an evergreen groundcover. It adapts to both full sun and deep shade, rich soils and poor ones—all it really needs to be sure of is evenly moist soil (it will need irrigation during periods of drought) and good drainage at all times.

Some wintercreeper cultivars are quite shrubby, but most will grow up walls or tree trunks if given a chance to do so. They climb via holdfast roots: Plant them where you want them to climb and let them make their own moves. Wintercreeper will not find trellises, latticework, or thin fences at all attractive for climbing. It prefers much broader surfaces, such as posts, trunks, and walls, where its roots will find something solid to sink their tips into.

Although hardy to Zone 5 (some cultivars to Zone 4), it will not climb well when exposed to harsh, cold winds, so it can be trusted to climb to any great height only in Zone 7 and above. In a well-protected spot, though, it will climb modestly, reaching up to 15 feet (4.5 m) or so even at the northern limits of its range. In mild climates it can reach up to 70 feet (21 m).

For groundcover use, plant smaller plants about 1 foot (30 cm) apart; up to 3 feet (90 cm) for well-developed plants in large containers. Wintercreeper is a fairly slow grower, so mulch well to prevent weeds from taking over while it spreads.

This is one climber not known for its exuberant growth! Not that it is weak—it simply grows slowly and densely, sticking tight to its host, without the long "whips" common to other vines. Pruning is therefore mostly a question of cutting out any winter damage, trimming back leading stems when they reach the limits of the plant's desired territory, and removing any reversions (some of the variegated types are not very stable). Prunings can be used to make cuttings: Those taken from lateral branches will climb more readily than those taken from vertical ones. When used as a groundcover, wintercreeper readily self-layers and the resulting "rooted cuttings" can be dug up and moved to other spots.

Warning: Wintercreeper berries are poisonous, though so rarely produced they aren't a major threat.

PROBLEMS AND SOLUTIONS

Mildew and fungal problems can be treated on a case-by-case basis. More serious are scale insects: Carefully inspect all wintercreepers before buying them, as this pest doesn't get around well on its own. Control it with horticultural oil.

TOP PERFORMER

Euonymus fortunei (wintercreeper): This is the only common wintercreeper that climbs (the others are shrubs or small trees) and also one of the rare evergreen species, so it really is in a class of its own. There are dozens of cultivars, including *E. fortunei* var. *radicans*, the most commonly available running/climbing variety, with dark green leaves. It is extra-hardy (to Zone 4). Most of the variegated types have an upright habit at first but will produce lateral branches that, if planted near a wall or trunk, will soon begin to climb. Examples are 'Emerald Gaiety' (white-margined green leaves with a pinkish tinge in winter) and 'Emerald 'n Gold' (similar but with yellow-margined leaves).

Hedera

Ivy

Plant Profile

Hedera: HEAD-er-uh

Foliage Color: Green and variegated

Foliage Time: Year-round

Length of Foliage Interest: Year-round

Height: 50 feet (15 m)

Spread: Indefinite

Garden Uses: Container planting, edging, erosion control, groundcover, rock garden, wall covering, woodland garden

Light Preference: Full sun to shade

Soil Preference: Humus-rich, moist, well-drained soil

Best Way to Propagate: Divide rooted sections in any season; take cuttings in spring or fall

USDA Plant Hardiness Zones: 7 to 9 (some cultivars to Zone 5)

A true triple-purpose plant, ivy can be used as an evergreen climber, a creeping groundcover, or a trailing container plant. In all cases, though, the dark, leathery leaves are evergreen, making the plant attractive year-round. Few plants are as variable as ivy, with literally hundreds of cultivars, most with star-shaped or maple leaf-shaped foliage, but there are also curly, fringed, or lacy leaves. Many ivies have white to yellow variegation, another plus.

GROWING TIPS

Ivies are tough, no-nonsense plants. They don't need any care, really—except pruning to keep them in check. They will tolerate almost any conditions except constant drought. Their degree of shade tolerance is legendary: Ivies will often grow in spots so dark they're otherwise totally devoid of vegetation. Not that they can't tolerate sun (they can, especially in cooler climates), but they do prefer shade or partial shade.

Ivy leaves and berries may be somewhat poisonous to humans. While the foliage is not terribly attractive to children, the black berries can and should be pruned off.

In colder climates, ivy can be grown outdoors only as a ground cover. Surrounding a bed of groundcover ivy with a footpath is enough to keep it within bounds; ivy won't stand much foot traffic.

If you want an ivy to climb, choose a species that is sufficiently hardy for your region, then plant it near a wall or tree trunk and let it grow. It will start to grow upward all on its own, hoisting itself thanks to numerous adhesive roots that will cling to almost any surface.

PROBLEMS AND SOLUTIONS

Ivies are not immune to insects and disease problems, including aphids, mealybugs, caterpillars, leaf spot, and powdery mildew, but they rarely seem to cause major problems.

TOP PERFORMER

Hedera pastuchovii (Russian ivy): This ivy grows over the widest range of any ivy, so almost any reader of this book can grow it. A cold-hardy ivy, it will make a good groundcover nearly everywhere and will climb even in Zone 5 (and warmer parts of Zone 4). The leaves are more rounded than English ivy, even heart-shaped, with paler veins, and they turn burgundy-red in winter. Height: 40 feet (12 m) or more. Spread: Indefinite. USDA Plant Hardiness Zones 3 to 9 (as a groundcover); 5 to 9 (as a climber).

MORE RECOMMENDED IVIES

Hedera canariensis (Canary Island ivy, Algerian ivy, Madeira ivy): This is a very large-leaved ivy grown as a groundcover or climber in Zones 8 to 10. The heart-shaped leaves with three to seven lobes are very shiny and measure up to 6 inches (15 cm) in diameter. 'Gloire de Marengo' (also sold as 'Variegata'), with leaves edged silvery white, is the most common cultivar. Height: 40 feet (12m) or more. Spread: Indefinite.

H. helix (English ivy): This is by far the most popular true ivy in culture and is offered in a bewildering choice of cultivars—some all green but many variegated white or yellow. Hardiness varies enormously from one cultivar to the next, with most not fully hardy beyond Zone 6, and some only to Zone 8. 'Baltica,' 'Wilson,' and 'Thorndale,' though, are hardy enough to be used as groundcovers in Zone 5 and as climbers in warmer parts of Zone 6. They have dark green leaves. Irish ivy (*H. hibernica* 'Hibernica,' often sold as *H helix* 'Hibernica') is very similar but not as hardy (Zones 8 to 10). Irish ivy can be invasive and is banned in some areas. Height: 40 feet (12 m) or more. Spread: Indefinite.

Hydrangea

Climbing hydrangea

Plant Profile

Hydrangea: hy-DRAIN-gee-uh

Bloom Color: White

Bloom Time: Early summer

Continued →

Length of Bloom: 2 to 3 weeks

Height: Varies by species; see individual listings

Spread: Varies by species; see individual listings

Garden Uses: Arbors and trellises, groundcover, specimen plant, wall covering, woodland garden; along paths, on slopes

Light Preference: Full sun to shade

Soil Preference: Humus-rich, evenly moist, well-drained soil

Best Way to Propagate: Sow ripe seed

USDA Plant Hardiness Zones: Varies by species; see individual listings

This is a most unusual and attractive deciduous climber, both in and out of bloom. It produces huge domed flowerheads, up to 10 inches (25 cm) in diameter, composed of a cluster of fairly modest, highly scented, whitish fertile flowers surrounded by a ring of much larger pure white sterile ones. They dry to a nice beige and last much of summer, adding to the plant's interest. The glossy dark green leaves are charming as well and turn a nice golden color in some climates (elsewhere they fall green). In winter the naked branches show off their bark: thick, flaky, and a rich cinnamon brown. It produces two types of shoots: climbing ones that cling to vertical surfaces, but also outward-growing ones. Thus, unlike most climbing plants whose leaves cling to their host like shingles, climbing hydrangea fills up plenty of aerial space. It's quite the show plant!

GROWING TIPS

Like so many woody vines, climbing hydrangea is adapted to a wide range of conditions, from deep shade to full sun (at least in cooler climates) and to most types of soil. For best results, though, give it a good, rich soil with even moisture and good drainage. It is only moderately drought-resistant, so it will appreciate a good mulch and occasional watering. In colder climates, plant it on the north or east side of a house or large tree for protection from the harsh winter sun.

This is the slowest of the vines described in this chapter. Plants grow like shrubs for the first few years and you begin to wonder whether someone hasn't sold you the wrong thing. After 3 to 5 years, though, it starts showing its true colors and sends out climbing shoots. Growth is ever so slow: It easily takes a decade for this plant to start to look good, and two or more for it to be at its best!

Warning: Don't try to force climbing by tying its woody branches to a support: They're not flexible like most other vines, and you're likely to damage them. Just let it do its own thing and it will climb when the time comes.

This is not a plant that needs a lot of pruning. Remove branches that are heading in unwanted directions whenever you notice them. If you want to cut an overgrown one back, do so over a period of several years, pruning as the blooms fade.

Although climbing hydrangea is easy to grow, it is also very difficult to multiply. Cuttings of semigreen wood are possible, but the failure rate is high. It may self-layer eventually and you could remove the resulting plants, but in general, either grow it from seed (if you're incredibly patient!) or buy new plants.

PROBLEMS AND SOLUTIONS

It's not usually subject to insects or diseases.

TOP PERFORMER

Hydrangea anomala subsp.*petiolaris* (climbing hybrangea): This is the usual form sold in nurseries, with beautiful heart-shaped leaves. You may find it sold under the name *H. petiolaris*. It differs most notably from the true species, *H. anomala*, because its leaves are heart-shaped while the latter has pointed leaves. *H. anomala* is just as attractive as *H. anomala* subsp. *petiolaris* but rarely available. Height: 9 to 50 feet (3 to 15 m). Spread: 9 to 35 feet (3 to 10 m). USDA Plant Hardiness Zones 3 to 9.

MORE RECOMMENDED CLIMBING HYDRANGEAS

Hydrangea seemannii (evergreen climbing hydrangea): This is a much rarer species and is only for those who have mild winters. It has similar blooms to *H. anomala* subsp. *petiolaris*, although smaller, and long, dark, glossy evergreen leaves. Similar, but with larger flower clusters lacking sterile blooms, is *H. serratifolia*. Both grow in shade but need some sun to bloom. Height: 10 to 50 feet (3 to 15 m). Spread: 7 to 17 feet (2 to 5 m). USDA Plant Hardiness Zones 8 to 10.

Menispermum

Moonseed

Plant Profile

Menispermum: men-ih-SPUR-mum

Foliage Color: Green

Foliage Time: Spring to fall

Length of Foliage Interest: 3 months or more

Height: 15 feet (4.5 m)

Spread: Indefinite

Garden Uses: Climbing plant, groundcover, hanging basket, woodland garden

Light Preference: Full sun to shade

Soil Preference: Humus-rich, moist, well-drained soil

Best Way to Propagate: Divide offsets at any time

USDA Plant Hardiness Zones: 3 to 9

It's surprising that moonseed is not better known. True enough, its small greenish flowers are not showy, but the leaves are very beguiling—large and oval to heart-shaped, often with intriguing lobes—and they totally cover the plant, meaning it can completely hide even the most annoying view. The only explanation for this plant's surprising lack of popularity is that it is a native plant, and unfortunately we tend to look down on our native varieties and praise importees instead. Consider doing an about-face and taking a second look at this unusual home-grown beauty: You won't regret it.

GROWING TIPS

As with many climbing plants, moonseed can be used as either a groundcover or a vine. As it climbs by entwining, it will need a support it can wrap itself around, such as a thin trunk, a post, a wire, or a trellis. Otherwise it will run across the ground and form a carpet of greenery.

It is native to the eastern third of North America, from Quebec and Manitoba down to the Deep South, so it is widely adapted to a nearly complete range of climates. It does best in rich, well-drained soils and is fairly drought-tolerant once established, though it thrives if mulched and watered regularly. In the wild it grows about equally well in sun and fairly dense shade and will do the same in your garden.

Like many vines, actually growing moonseed is a snap—it requires just about nothing from you to remain in top shape—but what it may well need is a bit of selective pruning. Given the chance, it will gladly leap from the trellis you choose for it to a nearby shrub or tree (or even telephone pole), then take that over, too. It also spreads by offsets produced by underground rhizomes, so be ready to cut it back whenever its stems outstep their bounds. As for the invasive roots, ideally you should always plant this vine within a root barrier so it can never escape and cause any problems. Otherwise you will find it popping up here and there, such as in your lawn.

Multiplication is usually done by digging up offsets appearing in the ground near the mother plant (if you used a root barrier) or anywhere within 10 feet (3 m) if you didn't. This can be done at any time the plant is not dormant. Fresh seed is rarely available unless you have wild moonseeds growing in your area. If so, harvest the seed when the grapelike berries are ripe (in early fall), remove the pulp, and plant the seed without delay. Germination will then take place the following spring, after the seeds have been exposed to winter's coolness. Stored seed, such as that offered in seed packs, often goes into prolonged dormancy and may need more than one period of cold in order to germinate. Seed-grown moonseed plants put on only modest growth the first year or so but, after that, quickly do their duty as a carpeting groundcover or object-concealing vine.

PROBLEMS AND SOLUTIONS

Moonseed is reputed to be essentially insect- and disease-free.

TOP PERFORMER

Menispermum canadense (moonseed, Canada moonseed): This is the only species with much of a commercial distribution and even then, it is quite rare in nurseries. Since there is a considerable amount of variety in the shape and size of the leaves, it's a shame that special cultivars are not available. Height: 15 feet (4.5 m). Spread: Indefinite. USDA Plant Hardiness Zones 3 to 9.

MORE RECOMMENDED MOONSEEDS

Menispermum dauricum (Asian moonseed): Much rarer in culture, Asian moonseed is very similar to its North American cousin, varying mostly in the number of flower clusters found at each axil (two instead of the single cluster found on *M. canadensis*). Since the flowers are insignificant anyway, there is no reason to prefer one species over the other: Choose whichever is the most readily available in your area. Height: 15 feet (4.5 m). Spread: Indefinite. USDA Plant Hardiness Zones 5 to 9.

Parthenocissus

Parthenocissus, Virginia creeper, Boston ivy

Plant Profile

Parthenocissus: par-then-oh-SIS-us

Bloom Color: Greenish white

Bloom Time: Early summer

Length of Bloom: 2 to 3 weeks

Height: Varies by species; see individual listings

Spread: Varies by species; see individual listings

Garden Uses: Arbors and trellises, background, container planting, groundcover, mass planting, wall covering, woodland garden; on slopes

Light Preference: Full sun to shade

Soil Preference: Humus-rich, evenly moist, well-drained soil

Best Way to Propagate: Take cuttings from spring to fall

USDA Plant Hardiness Zones: Varies by species; see individual listings

Parthenocissus will grow on almost anything. Trellises, fences, stumps, rusting cars: It does it all. In nature, it is famous for scrambling up the tallest trees, then leaping from one to the next, leaving dangling woody stems that would leave Tarzan's

Continued ➔

lianas in the dust. In the garden, people love the way it climbs vertical walls then drips down, creating a dancing green curtain. Don't look for attractive flowers: They're greenish and hidden by the leaves, but the deeply cut foliage is stupendous with its brilliant display of fall colors. When the leaves drop, they reveal blue or black berries that draw hordes of hungry birds in winter. No wonder parthenocissus is the queen of the hardy vines!

GROWING TIPS

These vines are among the most adaptable of all, seemingly immune to sun or shade, and any type of well-drained soil will do. They'll even grow in cracks in pavement!

Perhaps the nicest thing about parthenocissus is that they grow so quickly. Most woody vines take a few years to get going, but these babies are already well up your wall within a few months. Their tendrils are equipped with holdfasts that allow them to climb walls, tree trunks, or any vertical surface, yet the tendrils still twist so they can also mount trellises, latticework, fences, and the like.

Fast growth has a price, though, and that's likely to mean some pruning. Cutting back stems that try to work their way into the gutter or cover the window is likely to become an annual tradition if you grow them on a house. They can overwhelm an arbor or pergola in just a few short years—and did you really want them to completely cover that tree? It's best to learn to cut them back every few years, or even annually: They resprout quickly from the base and can easily grow back 20 feet (6 m) in a single summer.

Don't neglect parthenocissus as a groundcover either—most species create a superb green carpet in shade or in sun.

If you need more plants, just take cuttings: Both green, semi-green, and woody cuttings root readily. Plus, they self-layer where their stems touch the ground. You can also extract seeds from the fruit in fall: Sown outdoors, they'll sprout in spring. Of course, cultivars will not come true to type.

PROBLEMS AND SOLUTIONS

Mildew has an annoying habit of showing up in late summer but does little real damage, nor do other diseases. Leaf-eating insects are another story: Grape flea beetle, Japanese beetle, and leaf skeletonizer may require a few sprays with insecticidal soap.

TOP PERFORMER

Parthenocissus quinquefolia (Virginia creeper, woodbine): This ubiquitous climber is native to middle and eastern North America, from Mexico to Canada, but is now grown around the world, from the tropics almost to the Arctic Circle. Its compound leaves with five leaflets are reddish in spring, dull dark green in summer, and brilliant red in fall. The bluish black berries are evident only in fall and winter. 'Star Showers,' with leaves green-and-white in summer then pink-and-red in fall, is a weaker grower, ideal for spots you don't want to see overwhelmed. Englemann ivy (*P. virginiana* var. *engelmannii*), with smaller leaves, is commonly grown; *P. henryana* (Zones 7 to 9) has similar leaves but with a spectacular silver overlay. Height: 40 to 50 feet (12 to 15 m). Spread: 30 feet (9 m). USDA Plant Hardiness Zones 2 to 10.

MORE RECOMMENDED PARTHENOCISSUS

Parthenacissus tricuspidata (Boston ivy): A shiny-leaved version of the previous, with variable leaves, mostly maple-shaped but sometimes trifoliate. It conveniently dies to the ground each winter in cold climates, saving you a lot of pruning! There are several cultivars, including 'Veitchii,' with smaller leaves and purple fall color instead of scarlet; and 'Fenway,' with golden leaves. Height: 50 to 70 feet (15 to 21 m). Spread: 20 feet (6 m). USDA Plant Hardiness Zones 4 to 10.

Trachelospermum

Confederate jasmine, star jasmine

Plant Profile

Trachelospermum: tra-key-lo-SPUR-mum

Bloom Color: White

Bloom Time: Mid-spring to early summer

Length of Bloom: 6 weeks or more

Height: Varies by species; see individual listings

Spread: Varies by species; see individual listings

Garden Uses: Arbors and trellises, container planting, groundcover, hanging baskets, houseplant, mass planting, wall covering, woodland garden; on slopes

Light Preference: Full sun to shade

Soil Preference: Humus-rich, evenly moist, well-drained, acid soil

Best Way to Propagate: Take cuttings in spring or summer

USDA Plant Hardiness Zones: 9 to 10; frost-sensitive perennial grown as a tender annual

This vine gets its common name, Confederate jasmine, not from its home country, Asia, but from its great popularity in the southeastern United States. It is now just as popular in Southern California as well. It's a twining vine with shiny, dark green, oval leaves, tinted purple in winter, that are attractive in their own right. This plant's best attribute, though, is its beautifully creamy white flowers, with five petals slightly twisted to one side like a pinwheel. They are so highly scented, especially at night, it is most likely you'll smell it before you see it. This plant can reach considerable heights—or it can be grown as an evergreen groundcover or even as a houseplant. You choose!

GROWING TIPS

Confederate jasmine can be grown outdoors year-round only where temperatures don't drop much below 23°F (-15°C). It

prefers a rich, moist, acid soil and is not very drought-tolerant; keep it well watered in times of drought. Although full sun is fine when it's summering outside in the North, elsewhere it does best in shade or partial shade: The starry flowers truly brighten up the darkest corners. Indoors, grow in a medium-size pot on a small trellis, or train it to run around a hoop made from a wire coat hanger. Outdoors it will grow up arbors and pergolas, cover stumps, and even climb into trees.

For use as a groundcover, space the plants about 2 to 3 feet (60 to 90 cm) apart under tree or shrub cover or to the north of walls or buildings. It grows quite quickly, forming a dark green carpet about 10 to 16 inches (25 to 40 cm) tall.

Although Confederate jasmine is a fairly strong climber, it does have trouble getting started, so it is permissible to fix it to its support to start. With time, its twining, weaving stems will manage to work themselves in among the crossbars of a trellis or through latticework. Don't be afraid to prune back the excessively long shoots it sometimes produces. Otherwise, prune to shape it after it finishes blooming.

This plant roots readily from stem cuttings taken spring through fall outdoors, or year-round indoors. The cuttings exude a sticky white sap called latex: Plunge their tips into water to cause the sap to congeal before inserting them in moist growing mix.

PROBLEMS AND SOLUTIONS

Insects and disease are infrequent.

TOP PERFORMER

Trachelospermum jasminoides (Confederate jasmine, star jasmine): This is the most common species, with snow white flowers. Although very popular, it is not the hardiest species: Where it is borderline hardy outdoors, consider *T. asiaticum*, described below. 'Variegatum' has leaves beautifully marbled white with a pinkish tinge in winter. 'Madison' is a hardier selection, said to do well in protected spots of Zone 7. Height: 3 to 30 feet (1 to 9 m). Spread: 10 to 17 feet (3 to 5 m). USDA Plant Hardiness Zones 9 to 10.

MORE RECOMMENDED STAR JASMINES

Trachelospermum asiaticum (Japanese star jasmine): This is a hardier plant than the previous one and worth trying where Confederate jasmine is suffering. It has smaller leaves and similar but dangling flowers, creamy white at first, more yellow after a few days. Height: 3 to 20 feet (1 to 6 m). Spread: 10 to 17 feet (3 to 5 m). USDA Plant Hardiness Zones 8 to 10.

Working with Living Trellises

Barbara Pleasant

Any plant that grows lean and tall can be used to support twining vines. In spring, short peas are often happy to cling to clumps of ornamental wheat, and in the summer garden, you can use amaranth, corn, Jerusalem artichokes, or okra to support pole beans or long-vined limas. Single-stemmed sunflowers make great support plants in either a vegetable or a flower garden, where they can be used as living trellises for dainty asarina or more muscular purple-podded hyacinth beans.

There are a few things to keep in mind when using plants as trellises. Drenching rain combined with wind can cause tall plants to fall over, which becomes even more likely if the plant is top-heavy with the added weight of a vine. Giving the support plant a 2-week head start on the vine is important, too, because once vines get growing, they seldom slow down. Should a plant being used as a living trellis start to look like a leaning tower, tying it to a tall, slender stake may provide a temporary remedy.

Using an Unemployed Stump

When a treasured old tree must be removed, leaving a stump about 3 feet high instantly creates a great trellis for perennial vines such as passionflower or trumpet creeper. Tree roots often dominate the soil around a stump, so you may need to use a short

Continued ➔

rebar stake to probe about in search of a suitable planting pocket for a vine. If the stump is too short to provide vertical growing space for a vigorous vine, perhaps you can drill holes into the top that will support upright stakes. A single sturdy stake topped with a small weather vane or piece of metal sculpture can transform a vine-covered stump into a beautiful garden focal point.

Another option is to hollow out the top of the stump to create a planting space for cascading flowers or annual vines. If this seems like too much work, grow your vines in a large, heavy container placed on the stump. As the vines sprawl, they will cover both the container and the stump.

Plant Partners for Clematis

One of the most beautiful vines you can grow, clematis also makes a great team player when trained to wind its way through a small tree or shrub. The host plant provides support for the clematis, which in turn furnishes a bit of shade for its living trellis. In most cases, the clematis will bloom after its support plant has leafed out, so each blossom floats on a sea of lush foliage.

Clematis vary in color, bloom season, and ideal pruning times, but because there are hundreds of varieties to choose from, it is not difficult to coordinate them with exactly the right host plants. Don't worry that the host plant will shade out the clematis, because the vine will seek out sunny pockets in the tree or shrub's canopy and eagerly fill them in.

To begin one of these lovely liaisons, plant a clematis 2 feet from the base of the host plant. Clematis need rich, fertile soil with a near-neutral pH, so be sure to mix in some lime if your soil is naturally acidic. As the clematis grows, secure a slender stake between the vine and a low branch of the tree or shrub to help the clematis find its way. When pruning clematis trained this way, you can avoid future training sessions by pruning it back only to where it threads into the lowest branches of its host plant.

HOUSEPLANTS

Living with Houseplants

Barbara W. Ellis

Raising houseplants provides year-round gardening pleasure. Foliage and flowering indoor plants are generally easy to care for, and species can be found that will grow well in almost any part of your home. Houseplants are a great medium for experimenting with propagation techniques and satisfying the urge to garden, no matter what the weather.

Your first task in caring for a houseplant fresh from the greenhouse or plant store may be to repot it in a larger or more decorative container. Many gardeners assume that a plant should subsequently be repotted every few months. Actually, a plant should be repotted only if its roots fill its container, or if you prefer a different pot or type of soil mix for the plant. Spring is usually the best season to repot a houseplant. Wait until a plant finishes blooming before changing its container. Before repotting a plant, always check to see if its roots have run out of growing space.

To check the condition of a houseplant's roots, water the plant well and wait a few minutes for the moisture to soak in. Then turn the plant upside down, holding your palm flat against the soil with the stem between your fingers. Tap the edge of the pot lightly against the hard edge of a counter or workbench. The root ball should fall free of the container. If the plant will not come loose, run a kitchen knife around the inside edge of the container and then tap it again.

Rootbound plants have a mass of tangled white roots which fill the pot and may even protrude through the pot's drainage holes (if your plant is not rootbound, you can simply set it back into its pot). Healthy roots are usually creamy white and plump. Dead roots are brown or black and shriveled. Remove any dead roots before putting the plant in a new container.

Continued ➔

A layer of broken crockery at the bottom of the pot will keep soil from sifting out of the container, but will not help improve drainage. Be sure the crockery does not block the drainage hole. In this illustration, a pot shard is blocking the hole and will impede drainage.

How to Repot

Repot a houseplant in a container one size larger than its present pot. For example, if your plant is growing in a 6-inch pot, move it into an 8-inch container. Soak empty clay pots in water for several hours before placing a plant in them. Make sure that the plant's soil is thoroughly moist before transplanting.

You can fill the bottom of a new pot with a shallow layer of broken crockery so soil won't sift out.

Next, put in a layer of fresh soil, and insert the root ball so the old soil line is just below the new soil level. Make sure that the stem sits symmetrically in the middle of the pot. Fill in the edges with soil medium and compact it with your fingers or a pencil. Water the plant generously after repotting and keep it in a shady spot for several days.

Soil Mixes for Houseplants

Whether you mix your own potting soil or buy one of the many formulations offered in plant stores and garden centers, there are a few things all potting soils have in common. Although certain plants are grown in pots filled with a single ingredient—some orchids can be grown in fir bark, and bromeliads are often grown in sphagnum moss, for example—most plants grow best in a medium that combines several ingredients. Some of the ingredients in potting soil provide nutrition; others improve texture, enhance drainage, or aid water retention. For example, peat moss soaks up water, and sand ensures that the soil doesn't remain soggy; compost and other organic matter add texture and provide nutrition.

Types of Containers

Selecting interesting or unusual containers for your houseplants can be fun, but keep your plants' growing needs in mind when you choose pots. Plastic and clay are the most common materials for houseplant containers. Clay works well in a humid home. Use clay pots if you tend to water generously. Certain plants such as cacti, begonias, and orchids prefer clay pots.

Plastic is preferable if you have a normal or dry atmosphere in your home and tend to water sparingly. Many gardeners find that plants in plastic containers require less care and attention than plants in clay.

Both plastic and clay pots commonly come in two styles, "standard" and "azalea." Standard pots are as deep as they are wide—a standard 6-inch pot will be 6 inches deep and 6 inches wide. Standard pots work well for plants that have roots that plunge down, such as coleus and hibiscus. Azalea pots are shallower than they are wide. Plants that have surface roots or roots that grow horizontally grow best in azalea pots. Hanging plants, ground-covering plants, begonias, and most bulbous plants are best grown in azalea pots. You can set either plastic or clay pots inside a decorative container or basket.

For handsome and healthy houseplants, you'll need to match the conditions a particular plant prefers with the right soil mix. For example, while all potting soils retain water for the plant, some plants require more soil moisture than others. Most cacti are grown in mixtures that drain quickly and retain little moisture; most ferns, on the other hand, grow best in a mixture that remains moist but not soggy.

Soil pH affects how plant roots absorb both water and nutrients. The pH scale runs from 0 to 14, with the lower numbers reflecting acid conditions and the higher numbers, alkaline conditions. Most houseplants prefer to grow in a neutral to slightly acid soil with pH between 6.2 and 6.8. There are a few exceptions—gardenias (*Gardenia* spp.), hydrangeas (*Hydrangea* spp.), and acacias (*Acacia* spp.) are popular houseplants that will not thrive unless they are grown in an acid soil mix. Adding iron chelate to the soil will effectively acidify the medium. Store-bought mixes are usually carefully balanced to provide plants with a neutral pH. If you are making your own soil mix, be sure to check its pH.

INGREDIENTS

A good potting soil should start with soil and/or compost. Whatever you use, it's important that it be free of fungi,

soilborne diseases, insects, and weed seeds. Also, it should be well drained. Don't use plain garden soil—it is usually much too heavy when used in containers and tends to pack and crust. Also, unsterilized garden soil harbors fungi and insects. You can start with good garden loam or purchased topsoil, then sift it through a screen to remove rocks and large clods and sterilize it at temperatures of 150° to 180°F for 30 minutes. Sift and sterilize compost or composted manure before you use it, as well.

Sharp sand, also known as builder's sand, is another basic ingredient. It increases drainage, allowing soil aeration around the roots. Perlite and vermiculite are common ingredients that add no nutritional value but increase the air- and water-holding capacity of the mix. Peat moss is a good source of organic matter to hold moisture in the soil. Leaf mold is another common ingredient that offers nutrients and water-holding capacity and contributes to the structure of a mix. Leaf mold is not generally commercially available, but it can easily be homemade by composting autumn leaves.

To these main ingredients, you can add soil amendments such as lime, which neutralizes soil pH and provides calcium. Bonemeal is an excellent source of phosphorus and nitrogen. Wood ash is a source of potassium, but should be used sparingly as it has a potent effect on soil pH.

Commercial Potting Soils

Commercial potting mixes have a variety of ingredients, and not all manufacturers list the contents of their mixes. Choose a mix that specifies its contents on the package. Try to find a mixture that closely matches the components in the recommended homemade mixes below. Avoid mixes that contain chemical fertilizers.

RECIPES FOR POTTING MIXES

Potting mixes can be as simple or as complex as you wish. Here are a few that are suitable for a wide range of houseplants.

All-Purpose Houseplant Mixes

- One part peat moss, compost, or leaf mold; 1 part sterilized garden loam or purchased potting soil; and 1 part sharp sand or perlite.
- One part peat moss; 1 part sterilized garden loam or purchased potting soil and sterilized, composted manure mixed half-and-half; and 1 part sharp sand.
- Two parts sterilized garden loam or purchased potting soil; 1 part peat moss, compost, or leaf mold; and 1 part sharp sand or perlite.

Rich Houseplant Mix

Humus-loving plants grow better in a somewhat richer mixture.

- One part sterilized garden loam or purchased potting soil; 2 parts compost or leaf mold; and 1 part sharp sand or perlite.

Epiphyte Mix

Epiphytes are plants that grow on other plants—such as in the crotches of trees—without parasitizing them. They grow in leaf litter and other organic matter that collects around them. Several common houseplants, including some ferns, orchids, and bromeliads, fall into this category.

- One part sterilized garden loam or purchased potting soil; 2 parts leaf mold, peat moss, osmunda fiber, or shredded fir bark, or a mixture of all these ingredients; 1 part sharp sand or perlite; and ½ part crushed clay pot, brick, or gravel.

To each peck (roughly 2 gallons) of the above recipes, add ½ cup of bonemeal and ½ cup of lime.

Dividing Houseplants

Houseplants can be propagated in many different ways. Division is one of the easiest ways to produce new plants. The method varies slightly depending on the type of plant you are propagating.

PROPAGATING WITH OFFSETS AND SUCKERS

The easiest and most successful method for propagating houseplants is to divide off runners or offsets. Any plant that multiplies by producing "pups" can be divided. Episcias (*Episcia* spp.), African violets (*Saintpaulia* spp.), aloes (*Aloe* spp.), and mints (*Mentha* spp.), along with ferns, bromeliads, and many succulents, are among the many popular plants that can be successfully propagated by this method.

Separating a side shoot from its parent is as simple as it sounds. First, turn the plant out of its pot and examine the roots. For this method to succeed, all the separate divisions must have individual root systems. You'll probably find that each offset has vigorous roots which are intertwined with the parental root system.

Take the base of each crown in your hand and tease the roots free by pulling them slowly apart. Try not to damage any roots, and never pull at the foliage. When they're completely untangled, pot each plant separately, providing fresh soil for both the parent and its progeny. Keep the newly potted plants in a cool, shady spot for several days.

Some plants such as African violets, saxifrages (*Saxifraga* spp.), and episcias send out aerial runners with new plantlets dangling from the tips. Those plantlets won't send down roots until they can sink their feet into soil. To encourage root development, take a U-shaped hairpin and secure the plantlet firmly on top of a pot filled with loose, humusy soil (rich houseplant mix is fine). Leave the plantlet attached to its parent and keep the soil moist for two to three weeks while it develops roots. Then cut the runner. The dangling offsets of spider plants (*Chlorophytum* spp.) will even begin to initiate roots while hanging in the air. These can be removed from the parent plant and rooted in water or rich houseplant mix.

Continued →

DIVIDING RHIZOMATOUS PLANTS

Many common houseplants spread by underground rhizomes, which will send up new plantlets that can be cut and potted up. Rhizomatous begonias (*Begonia* spp.), snake plants (*Sansevieria* spp.), and many gesneriads form underground rhizomes that send up new plantlets. If left undivided, the plant will form an expanding cluster of growth, eventually choking itself into starvation. One solution is to keep repotting the growing plant. Another remedy is to divide the plant into two or more smaller specimens.

Turn the root ball out of the pot and use a sharp knife to cut the rhizome and its accompanying section of roots. The easiest method is simply to cut the root ball in half. You can divide it into small sections if you have many rhizomes sending up growing shoots. Repot all the divisions in separate containers, adding new soil around the sliced root systems. Put the plants in a shady spot and water them generously while they recover.

DIVIDING BULBS, CORMS, TUBERS, AND TUBEROUS ROOTS

Tuberous begonias (*Begonia* x *tuberhybrida*), oxalis (*Oxalis* spp.), achimenes (*Achimenes* spp.), dahlias (*Dahlia* spp.), and caladiums (*Caladium* spp.) are among the many popular houseplants that sprout from bulbs, tubers, or corms. Although each of these underground structures is different, they all store food during growth in preparation for dormant periods. And they usually produce new bulbs, corms, or tubers during their growing cycle, which can be divided when the plants go dormant.

To divide these plants, wait until the foliage dies back completely, and withhold water until the soil is dry. Turn the plant out of its pot and remove excess bulbs. They can be potted up right away or stored in a cool, dark, dry place until their growing season arrives. When stored bulbs begin to grow, pot them with growing ends up and begin supplying sun and water.

Increasing Humidity

Low humidity is one of the greatest problems encountered by indoor gardeners. During the winter, when furnaces and wood stoves are pouring out dry heat, indoor humidity is especially low. In extreme cases, homes can have as little as 10 percent humidity during the heating season.

If you suffer from chapped lips, dry skin, and clogged sinuses in the winter, you can imagine how uncomfortable your tropical plants must feel. Most tropical species require 40 to 60 percent humidity to thrive. When the air is dry, indoor plants lose water continuously through their leaf pores. The leaves look dehydrated, leaf edges turn brown, and leaves fall.

The easiest method of increasing humidity is to purchase a humidifier or vaporizer. However, there are less expensive methods of raising humidity for plants. When you group plants together, especially in a recessed bay window or window greenhouse, leaf transpiration increases the moisture in their immediate area. Setting pots on pebble trays filled with an inch of pebbles and ½ inch of water (remember to refill the tray as the water evaporates) also raises humidity for clustered plants. Simply putting a pan of water near a radiator, heat register, baseboard heater or on a woodstove can help increase the humidity in a room.

Misting plants is not an efficient way to combat a humidity deficit. Misting may raise humidity for a few moments, but only continual misting significantly increases moisture in the air around your plants. And, constantly moist leaves can develop fungal problems.

Pruning and Training Houseplants

If left to their own devices, most plants send a single stem shooting straight upward. A skillful gardener counteracts that tendency and coaxes the plant to bush into a handsome, shapely specimen. The secret is pruning.

Actually, although the scale is quite different, the principles of pruning houseplants differ little from those used for pruning trees. Early pruning can be used to shape and train a plant into an attractive shape. Heading cuts can be used to encourage bushy growth; thinning to remove unsightly branches and open up the center of the plant.

Pruning techniques vary depending on how severely you plan to prune. If your plant is young and has only a few sets of mature leaves, merely pinch the growing bud. Pinching is a type of heading cut that doesn't require knives or shears. Simply grasp the growing stem and snip off the terminal bud, with or without the top pair of leaves, using your thumb and forefinger. After pinching, the stem is not noticeably shorter, but the side shoots receive a "growth message" and immediately begin to develop. Regular pinching encourages branching and dense growth.

A saucer or tray filled with pebbles and water will provide much-needed humidity for houseplants.

Houseplants that Love High Humidity

Although nearly all houseplants benefit from increased humidity, the following require high humidity for best performance.

- *Allamanda* spp. (common allamanda)
- *Begonia* spp. (begonia, especially rex)
- *Bougainvillea* spp. (bougainvillea)
- *Calathea* spp. (calathea)
- *Gardenia* spp. (gardenia)
- *Mandevilla* (mandevilla)
- *Maranta* spp. (maranta, including prayer plant)

Gesneriad-family members such as African violets (*Saintpaulia* spp.), columnea (*Columnea* spp.), episcia (*Episcia* spp.), lipstick plant (*Aeschynanthus* spp.), gloxinia (*Gloxinia* spp.), and many ferns also thrive in high humidity.

If your plant is too tall, use a pair of sharp pruning shears and cut the growth to the desired height. Cut to either softwood or hardwood, and always cut just above a bud or a set of leaves. When judging the target height, remember that the plant will probably branch out just below the cut. Many older houseplants can be completely rejuvenated with a stern hardwood pruning. Use sharp, heavy-duty pruning shears to cut the stems back close to the base. New, fresh growth will shoot out within a few weeks.

ROOT PRUNING

If a plant is potbound, repot when you prune to provide nourishment for the new growth. This is especially important when pruning hardwood plants. If you don't want to move the plant to a larger container, prune the roots as well and pot the plant back into the same container.

To root prune, turn out the roots and, with a sharp knife, carve off an inch (or more for large plants) around the entire surface of the root ball. Work quickly, and cut the roots cleanly. Put the roots back in the pot, and add fresh soil. Keep the plant in the shade and water frequently until new roots grow.

Give Each Houseplant the Light It Needs

Roger Yepsen

Plants rely on light energy to drive the metabolic machinery of photosynthesis. With too little light, the machine slows and a houseplant performs poorly and may die. If the light is too intense, foliage may be burned. And one variety's sunlight requirement can cause another variety to drop all of its leaves. Plants are sensitive not only to the brightness of the light they receive, but to its duration and even the colors from which it is composed. For healthy windowsill greenery, you need to pay as much attention to light levels as to fertilizer and water.

A Grow-Light Like the Sun Itself

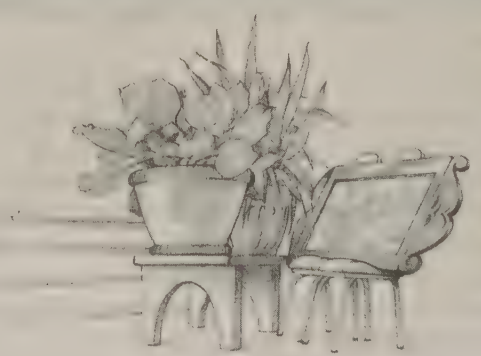
For years, greenhouse growers have relied on high-intensity discharge (HID) lamps for a blaze of light to supplement sunshine. For commercial operations, that supplemental light is especially important in northern states and in the winter. Most of us homeowners make do with too little light for many of the plants we'd like to grow indoors, but now HIDs are available in lower wattages. The smallest of them aren't terribly expensive, although powerful ones rated at 300 watts or so require a ballast (transformer) and are something of an investment. On the positive side, the bulbs last for 10,000 hours or more. And the quality of light resembles the sun's own, covering much of the spectrum. If you're serious about having a grouping of houseplants perform at their best, consider the purchase of an HID.

A Light Mover

Unless you can afford a bank of HIDs, you'll be limited to focusing a single fixture on one or a few plants that need a lot of light. Or, you can install a nifty automatic light mover that slowly propels the high-powered fixture along a ceiling track, increasing your growing area by 30 to 60 percent. There's no need to go up onto a stepladder to adjust a light this way and that—a 5-watt-motor does the work. Check the Internet for a supplier.

Use a Mirror for Nicely Groomed Plants

If you have a spare dressing mirror, you can use it to reflect the sun's energy and bathe the dark side of seedling flats placed by windows or large potted plants (especially ones in heavy clay pots). You not only make better use of the solar energy trickling



Make the sun do double duty by placing a space mirror behind large houseplants that aren't easily turned or moved. The plants will be more likely to grow to a well-rounded form because there is more than one light source.

Continued ➔

in through the panes, but also distribute it more evenly so that plants will grow symmetrically rather than leaning into the light. Painting adjacent walls and trim a semigloss white will also help bump up light levels. And you can cover the windowsill or window-side table with shiny Mylar, serving both to protect the surface below and to bounce light back up at the plants.

Add a Shelf

Light levels drop off quickly inside a house so plants needing high light levels should be placed as close to the window as possible. If your windowsills are narrow, consider adding a plant shelf to the sill for your houseplants. You can find a shelf kit (attach it just below your sill) or build your own sill extender (be sure to support the extension with a bracket). Or place a table right in front of the window so plants get direct light. Tie back any curtains (even sheer curtains) and be sure to keep windows clean to allow in the brightest light.

Getting It Right

If your houseplant isn't thriving, it may not be a case of too much or too little water or fertilizer. It may be that it isn't getting the right light. If plants develop white or brown patches or take on a yellowy tone, the light level may be too strong. Move the plant farther from the window or move it to a different, lower-light window.

Most plants that show signs of stress actually need more light. If a plant is leggy, if the leaves yellow and drop, or if the plant isn't growing at all, move the plant to a brighter location and see what happens.

Plants do drop leaves when you move them to a lower light situation or just bring them home from the store. Your indoor light conditions are probably lower than those in the store. Keep the plant in a higher light window and the plant will adjust to your conditions in a few weeks.

Harvesting and Using Flowers

Barbara W. Ellis

When the flower garden you've planned and nurtured finally bursts into bloom, you'll want to enjoy the blossoms to their fullest. Bouquets of cut flowers are the perfect way to bring the delicious fragrances and glorious colors of the garden indoors. Although flowers last longest when left in the garden, with just a little special care you can lengthen the life of cut flowers—adding days of enjoyment from floral arrangements. Longer vase life begins with something as simple as how you cut the flowers. There are a number of conditioning techniques that will also help lengthen vase life. Although the additional treatments listed below may seem like too much bother, many flowers will benefit from them. Try them, and you'll find they make a difference. Treat blooms immediately after cutting, before you soak them overnight.

Cutting

Scissors and fingers are not the tools of choice for harvesting flowers. Picking flowers by pinching them off with your fingers tends to tear the stems or uproot the plants. It also generally crushes the stem rather than severing it cleanly. Even scissors can bruise stems and close off the channels that carry water to the bloom. For best results, use a very sharp knife to cut flowers. As a general rule, cut across the stem at an angle to provide as wide a cut surface for water uptake as possible. This also prevents the stem from resting squarely on the bottom of the container, which would prevent water uptake. It's a good idea to have a bucket of water handy to receive your freshly picked flowers. Lukewarm water (100° to 110°F) is best; icy-cold water is a bit of a shock for the cut blooms.

Good timing also makes a difference in the vase life of flowers. Don't cut flowers during the heat of the day, when they may already be drooping. Instead, cut them during the cooler hours of early morning or in late afternoon or evening when they are not under stress from the sun.

Flower maturity is also an important consideration. Mature blooms that are full of pollen will not last as long as newly opened flowers. Choose blossoms that are just about to open fully. With some happy exceptions (daffodils and forsythia, for example), tightly closed buds will not open after they've been cut; they'll simply wilt when cut and put in water. Roses generally will open if cut once one outside petal has unfurled. Daisies last longest if picked when the flowers are fully open but the centers are still firm and slightly green. Spiky flowers like gladiolus, lupine, and delphinium will have the longest vase life if you select stems with lower flowers in full bloom and upper buds just on the threshold of opening. Snip off lower flowers as they wilt.

Conditioning

You can lengthen the vase life of flowers by conditioning them properly. That means allowing them to absorb as much water as possible as soon as they've been picked. Immediately after cutting and before arranging, stand flowers in deep water for six to eight hours—or, even better, overnight—in a cool, dark place. Immerse the foliage, but be sure to keep the flowers dry. Most flowers will take up warm water (around 100°F) more quickly. Conditioning will let the flowers drink in the water and be at their sturdiest for you to work with them. If the flowers have been out of water, recut the stems at an angle before plunging them in tepid water.

Surprising as it may sound, some flowers benefit from a hot bath immediately after cutting. Flowers that benefit from this treatment include windflower (*Anemone* spp.), broom (*Cytisus* spp.), bellflower (*Campanula* spp.), rose campion (*Lychnis coronaria*),

columbine (*Aquilegia* spp.), daphne (*Daphne* spp.), hellebore (*Helleborus* spp.), lobelia (*Lobelia* spp.), beard-tongue (*Penstemon* spp.), primrose (*Primula* spp.), and periwinkle (*Vinca* spp.).

To give your flowers a hot water bath, start by cutting the stems at an angle. Pour 1 inch of boiling water into a heat-resistant container. Protect the blossoms from steam with a collar of newspaper, then submerge the tips of the stems in the water for about one minute. Then plunge the stems up to the base of the flowers into tepid water (100° to 110°F) and give the flowers a good deep soak.

There are specific techniques suitable for different types of flower stems. Stems are generally classified as woody, milky, hollow, or soft.

WOODY STEMS

The blossoms of flowering trees, shrubs, and some vines have woody stems that have difficulty taking up water unless they are specially prepared. To increase water uptake, strip off the bark 1 inch above the cut, then lightly crush the tip of the stem to break down the fibers so they can more readily take up water. A wooden rolling pin or mallet will do the job with a few gentle taps; use a sturdy block of wood or a chopping board to save your countertop. An alternative method is to cut a series of slits up through the center of the base of the stem—again, to about 1 inch. After splitting the stems, soak them in tepid water for several hours. Dogwood (*Cornus* spp.), mountain laurel (*Kalmia* spp.), forsythia (*Forsythia* spp.), honeysuckle (*Lonicera* spp.), and fruiting trees such as apples and crab apples all benefit from this treatment.

Some other types of flowers have fibrous stems that also benefit from splitting before soaking. These include thistle (*Cirsium* and other genera), mallow (*Malva* spp.), and chrysanthemum.

MILKY STEMS

Stems that exude milky sap when cut must be sealed at the tip before they are arranged. To condition poppies (*Papaver* spp.), hydrangea (*Hydrangea* spp.), poinsettia (*Euphorbia pulcherrima*), or any other milky-stemmed flower, singe the stem tips immediately after picking for a second or so over a match or candle flame. With a sizzle, the cut will be sealed. You can also seal the ends with a hot water bath. Return flowers to water until time for arranging. If you need to cut the stems to length for the arrangement, you'll need to seal them again.

HOLLOW STEMS

One of the secrets of flower show winners is filling the hollow stalks of plants such as dahlias, delphinium, and lupine with water, then plugging the opening. Hold each stalk upside down to receive water from a medicine dropper or narrow-spouted watering can. Release any air bubbles by tapping the stem firmly with your finger. Use a tightly twisted wad of absorbent cotton as a stopper. Then stand flowers upright in deep water before arranging.

SOFT STEMS

Hyacinths, daffodils, and other soft-stemmed flowers last longer if you recut their stems under water to avoid the formation of an air lock. A basin or wide, shallow bowl full of water is perfect for dunking the stem while you cut it with your sharp knife. Be sure to cut stems at an angle. Then condition these flowers in cold water before arranging. When picked, the stems of daffodils exude a runny, clear sap that can clog the stems of other flowers arranged with them. To avoid this, soak daffodils in a separate container of cold water for two to three hours after cutting and before arranging. Try to cut the stems to the length you'll need in the arrangement before soaking them, to avoid recutting them.

Flower Arranging

Flower arranging doesn't have to be difficult. In fact, probably the hardest part is overcoming the fear of designing your first bouquet.

Arrangements can be as simple as daisies in a milk jug or as elaborate as a mixed bouquet for a buffet table, but if you're a beginner, it's best to start simple and work up. Just remember, flowers are always beautiful—it's hard to make them look ugly!

All good arrangements start with a few basic materials—fresh, properly conditioned flowers and foliage, tools, and containers. Knowing a few simple styling principles will help steer you in the right direction and encourage you to experiment.

MATERIALS

Take a tip from nature to inspire your designs and help you select the plant materials you use in arrangements: Your garden and the fields and forests nearby contain a wealth of colors, textures, and fragrances. Don't be afraid to try to re-create this natural beauty in your arrangements. Mix several types of flowers or foliage, select a variety of colors, or try new color combinations. Experiment with many types of materials to blend texture, color, and fragrance. For example, when selecting flowers, consider combinations of wildflowers, perennials, annuals, flowering shrubs and trees, roses, and herbs. Look to trees and shrubs, ferns, perennials, grasses, and herbs for foliage to add to your arrangements. Don't overlook the showy heads of ornamental grasses, seedpods, or shrubs with berries for unusual color and texture. Bring fragrance indoors with sweet-smelling blooms, but don't overlook pungent herbs—many of them make wonderful additions to bouquets. Crush a leaf between your fingers now and then to release their fragrance. Using flowers in varying stages of development will enrich the texture of an arrangement—combine unopened buds with fully blown flowers, for example.

Continued ➔

Containers

The choices for a container are almost limitless. Just remember that the container and flowers must complement each other to form an artistic unit. Often a container in a neutral color with simple lines is most effective, since it doesn't compete with your plant material for attention. That doesn't mean you should avoid a container with some individuality. Consider baskets, handmade pottery, and vessels of wood, pewter, or brass. Even seashells and rocks can hold flowers, especially in oriental or contemporary arrangements. All of these containers have the advantage of being opaque and will hide the mass of stems and any mechanical support system you've used.

A clear glass container lets the flowers take center stage. Stems showing through a transparent bowl make the flowers appear larger. Glass—cut crystal particularly—reflects light and makes flowers glow.

Some containers are so ornate that putting many colors in them creates confusion. But a monochromatic arrangement in one of these could be stunning—an all-white bouquet in an oriental vase, for example.

Tools

The tools you need for flower arranging aren't numerous, nor difficult to find. In addition to plant materials and containers, you'll need tools for cutting flowers, as well as mechanics, the tools used to hold flowers in place in their containers. Mechanics such as floral foam, pinholders, or chicken wire provide much-needed stability. They allow you to place stems exactly where you want them and hold flowers in position for best effect.

Mechanics

Experiment with some or all of the following mechanics in future arrangements.

Floral Foams. Perhaps the most widely used mechanic, floral foam bricks come in two forms, for either fresh or dried flower arranging. The bricks used for arranging fresh flowers absorb water and stems can be stuck in place anywhere in the brick for support. You can cut the bricks to fit any container. Use waterproof floral tape fastened to the edges of the container and across the top of the foam to hold it in place. (The container must be dry when you fasten the tape to it.) For best results, soak the foam for several hours in water before arranging flowers; it takes time for water to soak in, and sticking stems in dry foam can cause them to wilt.

Floral foam can be reused, so don't throw it away after a single use. After your arrangement has passed its prime, remove the spent flowers, taking care not to break the foam apart. Then store foam wet in a plastic bag if you'll be using it within a few days; otherwise, store it dry. When reusing, don't place new flowers in old stem holes in the foam. Air pockets there could stop the flow of water up the stem.

Pinholders. These are small, heavy implements that have round, oval, square, or rectangular metallic bases with many closely set pins molded into them. They're used primarily in low or flat containers such as those used in Japanese and contemporary arrangements, because they can be concealed in small containers. Secure the pinholder to its container with waterproof floral clay. Remember that container, pinholder, and clay must be dry when you fasten them together, to remain tightly in place.

Grid Mechanics. Chicken wire, the best known grid mechanic, is often used to hold flowers in position in large vases. To use chicken wire, cut a square of wire and fold the edges to fit tightly inside the mouth of the vase. Hold wire in place with waterproof floral tape. (The container must be dry when you fasten the tape to it.) You can also use waterproof floral tape to create grids over wide-mouthed vases, helping flowers to stay more upright.

Other Mechanics. Use marbles, pebbles, gravel, shells, or sand as mechanics by filling the container and using them to support flowers. These materials can provide interesting highlights to arrangements when used in clear or colored glass containers. Use clear marbles if you don't want mechanics to be so easily seen.

You can also design arrangements without mechanics. Flower and foliage stems, along with twiggy branches stuck in the mouth of the container, will hold flowers in their artistic poses.

Wiring

For most arrangements, wiring isn't necessary, but for some styles—especially formal ones—you may want to strengthen or bend a stem so it stays in position. To wire a bloom, insert the end of a piece of floral wire into the flower head. Then loosely wrap the remaining wire down around the stem. An alternative method used with some types of flowers is to guide the wire from the head down through the stem; this technique hides the wire and does not deter water flow.

STYLING PRINCIPLES

Whether you're planning a flower garden or making a flower arrangement, there are some basic design principles that will help you create a pleasing design.

Balance

Flowers have visual weight of size and color that must be balanced in a pleasing manner if an arrangement is to be attractive. For example, the visual weight may be distributed evenly throughout the bouquet or may be used at the base of an arrangement to provide a stable foundation. Balance is important in designing an arrangement regardless of the shape or style you've selected. Even though some styles are not symmetrical, all should be balanced. Otherwise, the

arrangement will look top-heavy or lopsided. In applying these principles, the general rule is to place flowers with more visual weight closer to the focal point of the arrangement. Other, less weighty flowers can be used to lead out and away from the center.

Flower Color. Generally, dark and bright colors carry more weight than light colors. Dark colored flowers, such as maroon tulips or deep purple bearded iris, or bright colors, such as brilliant orange marigolds or flaming pink peonies, have more weight than blooms of equivalent size in light colors such as white, lilac, or pale yellow. Try to balance the distribution of each throughout the arrangement. An arrangement with large, brilliantly colored blooms at the top and white or other light flowers at the bottom will look top-heavy; one with dark flowers all to one side will look lopsided.

Dark colors can also be used to add visual weight to the base of an arrangement to add stability. Intersperse light colors throughout a bouquet to reflect more light and add an airy effect. This will also break up heavy masses of color.

Flower Size. Of course, large flowers have a heavier appearance, or visual weight, than small flowers. Try to avoid the top-heavy look of an arrangement with large flowers at the top and smaller, more delicate-looking flowers beneath. (If you want to repeat the color of a large flower at the very top of an arrangement, use a bud or partially opened flower that won't "weigh" as much.) You can use several small flowers to balance a larger one. Large flowers are effective when used to create visual weight near the center of an arrangement. Increase the visual weight of small flowers by allowing them to protrude farther from the center of the arrangement than large flowers. Small flowers often are used as fillers in arrangements—they're interspersed throughout the arrangement to add a feathery touch and delicate color.

Flower Shape. You'll also want to balance the many different shapes of the flowers in the arrangement. Use tall, spiky flowers to direct the eye outward, by placing them around the outside of a bouquet. Or use them to make a flourish at the tips of a design, making the arrangement "reach." Round, denser flowers draw the eye toward the center of the arrangement.

Flower Texture. Finely textured flowers add an airy quality to bouquets; coarser flowers give the arrangement a more solid appearance. In most cases, it's best to intersperse the various textures you're using so that they are distributed evenly throughout the bouquet. However, you can also use texture to create an accent. For example, seed heads of ornamental grasses can be used to create an attractive plume in an arrangement.

Proportion

An arrangement is said to be in proportion when its scale is in good relationship with its surroundings. This means that the different elements of an arrangement—flowers, foliage, and container—should all go well together and create a harmonious composition. A huge bouquet in a tiny container would be out of proportion just as would an arrangement mixing only 3-inch-wide zinnias with tiny tufts of baby's-breath. Mix a variety of sizes of flowers and foliage, and choose a container that is appropriate in size and style to the flowers you're using.

Repetition

Repeating one element in a design helps unify an arrangement and create a cohesive whole. You can repeat particular flowers—red zinnias, for example—or repeat a color using many different flowers all of the same or closely related colors, such as yellow marigolds, yarrow, and chrysanthemums. You can also repeat specific combinations of flowers throughout a bouquet, or repeat lines in a geometrical arrangement.

STYLES AND SHAPES

Floral designers use many different styles and shapes of arrangements to suit various tastes. An arrangement can have an airy, informal style, with flowers gathered in a loose bouquet—a handful of mixed wildflowers placed in a vase, for example. Formal arrangements tend to have a more compact and regular style—such as a low composition for the center of a dining room table.

There are eight traditional shapes for arrangements: round, triangular, L-shaped, crescent, horizontal, contemporary vertical, traditional vertical, and Hogarth or S-curved. Some shapes are particularly suitable for certain kinds of occasions. The horizontal arrangement, for example, is the best choice for a centerpiece on a formal dining table. This low arrangement won't interfere with conversation across the table.

Whatever shape arrangement you're making, start by deciding where to put the center of your design. This will be the imaginary source from which the flowers appear to grow. When you place flowers in the container, aim stem tips at this focal point to give the bouquet a more natural appearance. As you work with the flowers, be sure to remove foliage that would be below the water line.

How to Make a Flower Arrangement

A simple round arrangement makes an excellent centerpiece for informal dining. You can create a compact, formal Colonial-style mound of flowers, or a colorful, loose, informal array of your garden favorites. Whatever the style, the round arrangement is a good choice for learning floral design. Just follow the steps listed here.

1. Begin by preparing the container for designing. Cut a piece of wet floral foam to fit snugly in the container you've selected. Then fix it in place with two strips of floral adhesive tape. (Or use a pinholder secured with clay instead.) Fill the container with water. Place the container on a lazy Susan so that you can rotate it with ease while designing to view the arrangement from all sides.

Continued ➔

2. In a round arrangement, the focal point is the center of the foam block or pinholder. Aim your stem tips toward this point. Start by placing some of the foliage you've gathered to cover the foam base.
3. Place the largest flowers next. Position some very close to the focal point and some farther away at various distances out and up from the center, roughly outlining the round shape of the arrangement. Check to make sure the arrangement is balanced, with visual weight evenly distributed throughout the bouquet.
4. Create contrast by adding linear material such as tall, spiky flowers, seed heads of ornamental grasses, and twigs or berry branches alongside the first few flowers placed in the center.
5. Define the roundness further by filling in large gaps with medium-size flowers and foliage.
6. Check to make sure the floral foam is covered with foliage.
7. Round out the bouquet by filling any spaces with small, dainty flowers. Baby's-breath (*Gypsophilia* spp.) makes a good filler for this purpose.

MAKING A DRIED ARRANGEMENT

The steps are almost reversed in making a dried arrangement. You may need to use floral wire to strengthen the stems of dried flowers, or wire small clusters of flowers together and insert them all together. First, cover the mechanics with sheet moss, which is available from floral suppliers. Then define the round outline with small filler material such as dried baby's-breath or statice. Build the arrangement by adding medium-size flowers and then large flowers. Last, carefully place the linear material such as ornamental grass seed heads or dried spikes of lavender for accents to soften the edges.

How to Press Flowers

Pressing is one of the best ways to preserve flowers and retain them as treasured keepsakes, whether they're from your wedding bouquet or a child's walk in the woods. You can use pressed flowers to make a variety of decorative items such as pictures, candles, frames, stationery, cards, and bookmarks. These items can hold their color and artistic value longer than dried flower arrangements, wreaths, or potpourri.

SELECTING PLANT MATERIAL

You can gather an abundance of materials for pressing in meadows and forests, or you may already have plenty of flowers and foliage in your garden. Choose flowers with heads that will flatten well. Flowers with simple shapes such as violets are easier to press than large, trumpet-shaped lilies, for example. Various leaves, skeletonized or fresh, take nicely to pressing and add a fine contrast to colorful flowers. You can also press grasses, herbs, tree leaves, and ferns. Try pressing plants and flowers in different stages of growth: fronds and fully developed ferns; flowers and their buds. For large, double flowers such as peonies or roses, try pressing individual petals and re-creating the "flower" by arranging the separate petals in your compositions. Don't be afraid to experiment. In addition to the materials listed above, try mosses and lichens or even slices of fruits and vegetables. With any new material, it's a good idea to jot down notes about what steps you take as you discover what works for you.

Harvest plant material when it is dry and stems are full of water. The best picking time is on a dry day in the late morning. Press your gatherings shortly after cutting, or keep them in a container of water until you're ready to press them. Remember not to press flowers when wet or wilted.

THE FLOWER PRESS

You don't need any elaborate supplies to experiment with pressing flowers. Start with a heavy, hardcover book or a telephone directory for a press. Place the materials you're pressing between sheets of blotting paper (available in art stores) to prevent ink from staining the flowers—and moisture from the flowers from staining the book—then insert them between the pages of the book. Stack heavy books or bricks on top of the book press for extra weight.

You can construct a sturdier press from plywood. A plywood press enables you to apply more pressure to the flowers, quickening the entire process and giving better results. Cut two pieces of heavy gauge plywood to equal dimensions; rectangles that will accommodate a folded sheet of newspaper—about 14 by 16 inches—are ideal. Drill a hole in each corner, then use long bolts with wing nuts to connect the two boards at each of the four corners. Use the wing nuts to tighten and loosen the press to adjust pressure.

Plant material is pressed between the plywood boards in sandwiches of absorbent paper such as recycled paper or newsprint and blotting paper.

First, place a layer of absorbent paper on the board—several folded sheets of newspaper are ideal. Next, put down a layer of blotting paper. Arrange your flowers on the blotting paper. Try to use as much space on the blotting paper as possible when spreading out the flowers, but don't overlap the specimens—they'll stick together. Arrange flowers so that you'll end up with a variety of stem curves, as well as open flower faces and profiles, so you'll have plenty of choice for your compositions. It's best to keep all of the same type of flower, or at least all of the same color, in one layer, so you'll be able to find them easily. You may even want to label the layer. After you've arranged the flowers, add another piece of blotting paper, several more sheets of newsprint or absorbent paper, and then more blotting paper and another layer of flowers. Make as many layers as you want, as long as the corner bolts that hold the plywood pieces together will span the depth.

For best results, keep your press in a warm, dry place, because too much moisture in the environment may promote mold to form. After the first few days of pressing, change the absorbent paper between layers, but leave the blotting paper intact so you don't disturb your flowers. Check for wetness periodically for the remainder of the pressing process. Keeping the paper dry and pressure strong will quicken the drying process for most plant materials and yield more vivid colors. (Very succulent materials, however, require less pressure but more frequent paper changes.)

Materials are dry when they're crisp to the touch—this should take at least two weeks. Store your dried flowers in the press until you're ready to use them.

Making a Pressed Flower Picture

Creating a pressed flower picture is like painting one. Use the flowers as brushstrokes of color and texture; leaves as background. You can create bouquets or depict scenes with dried flowers, and it's easy to rearrange the dried materials until you have a composition that pleases you.

1. Begin your picture by choosing a paper or fabric background. The background should be simple and not overpower your picture—a sheet of mat board is fine. The background should contrast with the flowers to play up their colors. For example, use a dark background if you'll be working with mostly light flowers.
2. Cut the background to the size and shape of your frame. If you're using paper or fabric, mount it with spray adhesive on a piece of mat board or foam core. Spray adhesive, unlike regular white glue, won't leave bumps on the background surface.
3. Start building your picture by putting down the larger backdrop flowers and leaves. These can be skeletonized leaves, fern fronds, long flowers, and leaves. Move the delicate plant material carefully with forceps or tweezers.
4. Next, arrange the bolder, more colorful flowers that will form the center of your arrangement. Layer some of these over the stems of backdrop elements. (Don't forget, unless you plan to frame with a mat, the finished picture must be flat. You may need to cut away the plant parts that won't be seen.)
5. Position small, dainty flowers for accent, and cover any unsightly stems with pressed leaves, lichens, or moss.
6. To assemble the picture permanently once you've created an arrangement that pleases you, turn the arrangement upside down or sketch it so you'll remember how all the elements were arranged. To turn upside down, cover it with a piece of heavy cardboard, hold tightly, and turn. Then fasten down the elements of your design one at a time, starting with the background material. Use rubber cement or water-soluble white craft glue that dries clear. Use a toothpick to dab tiny amounts on the backs of flowers and foliage. Let the glue dry overnight. Then cover your picture with glass and frame it.

Drying Flowers

Arrangements, wreaths, and other projects made from dried flowers have nearly universal appeal. Fortunately, drying flowers is easy and requires little more than adequate storage space and an abundance of plant materials. Many gardeners only think of drying annual flowers such as cockscomb (*Celosia* spp.), strawflower (*Helichrysum bracteatum*), and gomphrena (*Gomphrena globosa*) in the late summer or fall. But there are flowers suitable for drying all seasons of the year, in your garden and in the meadows and forests around your home. For example, daffodils and tulips dry well in desiccants such as silica gel. Pussy willow is another early spring feature that is easy to dry. In spring and summer, try drying blooms of ornamental onions (*Allium* spp.), astilbe (*Astilbe* spp.), and yarrow (*Achillea* spp.), all of which are easy to air-dry. In fall, ornamental grasses make wonderful additions to dried bouquets. Also try ripened seed heads from weeds, perennials such as blue false indigo (*Baptisia australis*), twigs, and vines. Don't be afraid to experiment with many different types of plant materials.

The traditional way to dry flowers is to air-dry them in bunches. The fragrance and nostalgic charm of flower bunches suspended from a drying rack are just as enjoyable as the dried blossoms and grasses will be in an arrangement later. Although air-drying is still popular, desiccants have widened the range of flowers that can be dried successfully and microwave drying has shortened the process to a matter of minutes or hours, not days or weeks. Regardless of the technique you choose, there are a few pointers that apply to all of them.

Continued →

TIPS FOR SUCCESS

- Don't harvest flowers or other plant material when the weather is cloudy and damp or the plants are wet. If you should find a few hidden drops of dew on material you've harvested, use the edge of a paper towel to gently absorb the water before drying.
- Don't harvest plant material that is wilted. If you can't dry out material immediately, stand it in water in a cool, dark place until you can get to it.
- Select the most perfectly formed flowers you can find; drying will accentuate any flaws.
- Experiment with flowers at various stages of development—blooms often open further as they dry. But don't pick flowers which have been fully open for several days, as they're more likely to turn brown and shatter.
- Keep a notebook to jot down what works and what doesn't—what you harvested, what stage of development it had reached, how you dried it, and other methods you'd like to try to improve your results.
- If you've a specific arrangement in mind, dry perhaps twice as much material as you think you'll need. Then you'll not be caught short if some flowers do not dry perfectly or are damaged in storage.

Plants for Air-Drying

There are several ways to air-dry plant material, and some plants are better suited to one method than another. Here are lists of plants suited to each method.

Plants to Hang Upside Down

Achillea spp. (yarrow)
Allium spp. (ornamental onions and chives)
Ammobium alatum (winged everlasting)
Armeria maritima (thrift)
Artemisia spp. (artemisia or wormwood)
Carthamus tinctorius (safflower)
Celosia spp. (cockscomb)
Delphinium spp. (delphinium or larkspur)
Limonium spp. (statice)
Lunaria annua (money plant or honesty)
Salvia spp.(sage)
Sedum spectabile (sedum)
Solidago spp. (goldenrod)
Tagetes spp. (marigold)

Other materials that can be dried hanging upside down include seed heads of *Clematis* spp., Oriental poppies (*Papaver* spp.), and coneflowers (*Echinacea* spp. and *Rudbeckia* spp.); seedpods of many plants including blue false indigo (*Baptisia australis*); rosebuds; cattails (*Typha* spp.); and branches of pussy willow and knotweed (*Polygonum* spp.). Blooms of globe amaranth (*Gomphrena globosa*), strawflower (*Helichrysum bracteatum*), and everlasting (*Helipterum* spp.) are best wired before they're hung to dry for the stems aren't strong when dry and tend to droop.

Plants to Dry Right Side Up

In addition to the plants listed here, grains and ornamental grasses also can be dried right side up.

Echinops spp. (globe thistle)
Gypsophila paniculata (baby's-breath)
Physalis alkekengi (Chinese-lantern plant)
Cotinus coggygria (smoke tree)

Dry the following plants right side up, but set the stems in ½ inch of water: *Calluna* spp. (heather), *Hydrangea* spp. (hydrangea), and *Moluccella laevis* (bells-of-Ireland). Florist's proteas (*Protea* spp.) and other related florist's flowers, including *Banksia* spp., *Hakea* spp., and *Grevillea* spp., can also be dried in this way.

Dry with Support

Slip the stems of the following plants through screens or hardware cloth to provide support for the flower heads.

Anethum graveolens (dill)
Daucus carota var. *carota* (Queen-Anne's-lace, wild carrot)
Foeniculum (fennel)
Heracleum spp. (hogweed)
Leontopodium alpinum (edelweiss)

Dry Flat on a Screen

Many plant materials can be spread on screens or layers of absorbent paper for drying. These include dock (*Rumex acetosa*), bamboos and grasses (which can also be dried by hanging or upright), fungi, twigs, and sprigs of lavender (*Lavandula* spp.).

- To protect plant material from shattering or reabsorbing moisture from the air, spray after drying with matte-finish plastic craft sealer or hair spray.
- Flowers dried with silica gel can reabsorb moisture. You'll need to display them in an airtight container, such as a Victorian bell jar, or store them until the air is less humid, such as during the winter heating season.
- If you're not using them right away, store flowers in flat boxes in one or two layers separated by tissue paper so they can be easily located later without damaging your handiwork. Add a few mothballs to repel rodents and moths. Silica-gel-dried flowers should be stored in an airtight container with silica gel or dry sand in the bottom.

AIR-DRYING

Air-drying is a simple method for preserving large quantities of plant material. Results differ from plant to plant. Some such as cockscomb (*Celosia* spp.) will dry nearly perfectly, with attractive form and brilliant color. The colors of some blossoms will fade, but these can be used to impart an antique aura to nosegays or arrangements.

Flowers with fat, moist blossoms or many petals such as peonies (*Paeonia* spp.) generally do not air-dry well. They drop their petals, fade, or shrivel past recognition. (See "Plants for Air-Drying" above for a list of the flowers to start with for each of the methods described here. You can experiment with other flowers as you become more experienced.)

The ideal spot for air-drying is a dark room with warm, dry, gently moving air. The dryness of the air will affect whether the process takes a week or three weeks. Consider an attic, dry basement, garage, shed, or closet.

Many flowers can be hung upside down to dry. Strip foliage from their stems and make small bunches of them. Put no more than five in a bunch, and stagger flower heads so they don't touch. Make a slip knot with a string or rubber band down toward the stem ends to hold them tightly together. Then hang them from hooks, pegs, coat hangers, or racks that are either suspended from the ceiling, along walls, or freestanding.

Some flowers and plants dry better when placed right side up in a widemouthed container. Spread the stems out so they aren't crowded or crushed, and so you'll be able to separate them easily. Try drying some of the plants you normally hang to dry, to create a pleasing curve in the stem. Other plants should be dried in a similar container, standing in ½ inch of water.

Round, flat flower heads need support to dry flat. Slip stems through a screen, such as ¼-inch hardware cloth, letting heads rest faceup on the screen. Some materials are best laid flat to dry on a wood-framed screen that lets air circulate beneath. Or use an absorbent surface such as newspaper; turn occasionally during the drying process.

DESICCANTS

Drying agents, or desiccants, not only speed dry as they absorb water from petals and leaves but also expand the range of flowers that you can preserve. The flowers dried by this method much more closely resemble fresh flowers in color and form.

Of the commercially available desiccants, silica gel works fastest. It now comes very finely ground for use with flowers and can be sifted into blooms to encourage them to dry quickly without leaving bumps from coarse grains on the petals. Silica gel is available from hobby or craft stores, florists, and garden centers, as well as mail-order suppliers. Although it's expensive, it can be reused indefinitely. It usually comes with blue "color indicator" crystals that change color when the silica gel is saturated with moisture. To reactivate it by drying it out, spread it on a flat baking pan and heat it in a 250°F oven until the original color returns.

Drying flowers with desiccants such as silica gel is easy. Just follow these steps.

1. Select an airtight container, such as a cookie tin. Since different flowers dry at different rates, plan on using a separate container for each type of flower.
2. Gather flowers and cut stems to 1 inch or so in length. If you expect to need wire stems for arranging, it's a good idea to wire them now. To wire a bloom, insert the end of the wire into the flower head. Loosely wrap the remaining wire down around the stem. An alternative method used with some types of flowers is to guide the wire from the head down through the stem.
3. Spread a ½-inch layer of silica gel on the bottom of your container. Then set the blossoms on the silica gel, bending wired stems out of the way as needed. Set daisy-like flowers facedown; complex, many-petaled flowers like roses or carnations faceup. Space the blossoms so they don't touch one another.
4. With a spoon or measuring cup, gently pour silica gel around the blossoms, first filling in support underneath each bloom and then making sure all crevices in the bloom are filled. Cover with another ½-inch layer of silica gel. You can make additional layers of flowers if the container is deep enough.
5. Tightly close the container and label it with date and contents.
6. If you're drying simple flowers such as small daisies, open the container in about two days and gently shake it until a few petals appear. If they feel like crisp paper, carefully pour off silica gel into another container and remove flowers. For fleshy or more complex, many-petaled flowers, wait several days before checking.
7. After the flowers have dried, partially refill the container with a layer of silica gel and insert flower stems up to, but not covering, the petals. Close the container and leave for another two to four days to finish drying. This is especially necessary with more complex, many-petaled flowers, like roses.

Continued ➔

8. Check the blooms regularly, and remove them when they are fully dry. With a small camel's hair paintbrush, dust off any clinging silica gel. Protect blooms from shattering with a drop of clear-drying glue at the flower's center and base.
9. Keep a record of drying times you use for each flower type so you develop a sense of what works best. Flowers immersed in silica gel for too long will become overly dry and be very brittle, so you'll want to get it just right.

MICROWAVE DRYING

Microwave drying is not only speedy for flowers, it also solves the problem of how to preserve foliage, which shrivels or changes color when dried by any other method.

You can dry autumn leaves, fern fronds, or other foliage in your microwave. First, to protect the microwave, put a cup of water at the back of the oven. Replace the water each time you run the microwave. Fold a paper towel in half and put the leaves to be dried inside it. They should not overlap. Place the paper towel in the microwave and place a microwaveable dish on top to prevent the leaves from curling. Cook two minutes on high power, then remove the leaves. If they are dry and crisp, they are done. If they seem almost dry, overnight air-drying will most likely finish them. If they've lost color or appear too dry, try a new batch and less cooking time. Use a dry paper towel for each new batch of leaves.

You can also dry flowers in the microwave using silica gel. Dry one flower at a time, using a small microwaveable container that is about 3 inches taller than the flower. Put in a layer of silica gel, insert the blossom, then carefully cover the flower, filling in all nooks and crannies with the silica. (Don't wire blooms before putting them in the microwave. If you need to wire them, do it immediately after they're done, before they cool.) Add a layer on top, leaving about 2 inches of space between the top of the gel and the top of the container.

Place a cup of water at the back of the microwave, and replace the water each time you do a new flower.

To eliminate guesswork, place a microwave thermometer in the silica so it does not touch the sides or bottom of the container. Put the container in the microwave and heat on high for 30 to 60 seconds at a time, until the thermometer reads 200° to 220°F. Use a rotating rack or turn the container every 30 seconds. Remove the container from the microwave with thermometer still in place. Allow silica to cool until the temperature reads 70° to 80°F before removing the flower. Keep a record of cooking times and results for various flower types so you can make adjustments if needed. If flowers turn beige, reduce cooking time the next try.

After the flowers have dried, carefully sift away the silica gel. Insert flower stems up to, but not covering, the petals, in another larger container with a fresh layer of silica gel. Close the container and leave the flowers for another two to four days to finish drying. Then clean the flowers with a small paintbrush and spray with sealer.

Making a Dried Flower Wreath

Wreaths are a delightful way to decorate doors or bring nature into your home. They also make treasured gifts or keepsakes, especially when the flowers are from your own garden.

There are a variety of ways to make a wreath, partly because of the many choices for wreath bases. You can start with a wire frame and cover it with small bunches of dried baby's-breath (*Gypsophila* spp.), statice (*Limonium* spp.), or dried 'Silver King' Artemisia (*Artemisia ludoviciana* var. *albula*) for filler. Wrap floral wire around the stems of the bunches and wire them to the frame. Continue adding and wrapping bunches until the entire frame is covered. For a quick wreath, intersperse small bouquets of mixed dried flowers for the bunches of base material as you go.

You can also start with a base made of straw or Spanish moss, both of which can be purchased at craft stores or garden centers. Start with a background filler—as with a wire frame, baby's-breath, statice, or Artemisia are fine—and insert it stem by stem until the entire base has been covered. Then add accent flowers to dress it up. Small bouquets of colorful dried flowers wired together—plus dried herbs for fragrance—are easy to add by poking them in place. Or you can fasten them with hairpin-shaped floral pins or bent pieces of wire. You can add just a few bright accents and intersperse them with stems of more neutral colors. Keep in mind that you want a harmonious composition of color and texture.

You can also make a wreath base from trailing vines, such as grapevine and trumpet vine. Harvest the vines in summer or fall when they are pliable, and use them immediately so they don't become brittle. Trim off leaves and green growth. Begin the wreath by looping a circle with the vine in the desired size for your wreath. Continue making circles, weaving the ends in and out around the initial loop. Once you've woven one vine in place, you can add another until the wreath is as thick as you desire. Tuck the ends in when you're finished. If you like the look of dried grape tendrils poking out in all directions, save some lengths of vine with attractive tendrils until the end, then weave or wire them in place. Once you've created the vine base, add accent materials by wiring or using hot glue to fasten them in place. Don't plan on covering the entire base with dried flowers, since the vine wreath adds an attractive, woodsy touch.

Attaching Flowers

There are several ways to attach flowers to a wreath. It's generally easiest to wire small bunches of filler or background material together and then insert them. If you're using a straw or Spanish-moss-based frame, you can wire flowers to wooden floral picks, which come with a short piece of wire attached just for this purpose. Just gather a few stems together, wrap the wire around them, and poke them in place.

The Best Herbs for Indoors

Basil (*Ocimum Basilicum*): annual, to 2 ft. tall. Needs full sun; 6.0 optimum pH. Give basil well-drained soil, and water whenever the soil surface begins to dry. Harvest by snipping the growing tips frequently to keep plants bushy and prevent flowering. Prefers daytime temperatures in the 70s and nighttime temperatures in the 60s. Don't let the temperature drop below 50°F. Plants will remain productive for three to six months if prevented from flowering. Try handsome compact cultivars such as 'Spicy Globe' and 'Green Globe.'

Bay (*Laurus nobilis*): perennial tree or shrub, to 40 ft. tall (though not indoors). Needs full or part sun; 6.2 optimum pH. A slow grower, bay will take years to reach 2 ft. in a pot. Allow the soil to dry between waterings. Pot up one size in the spring. Prefers daytime temperatures in the 60s and nighttime temperatures in the 50s, but can take temperatures in the low 40s. Allow plants plenty of room for good air circulation. Harvest by cutting off individual older leaves as needed or to dry.

Chives (*Allium Schoenoprasum*): perennial, to 1½ ft. tall. Needs full sun; 6.0 optimum pH. Prefers daytime temperatures in the 70s and nighttime temperatures in the 60s, but can take temperatures in the low 40s. Water when the soil begins to dry, and give plants room for good air circulation. Repot whenever plant looks crowded (you can divide clumps and pot up individually as well). Plants will live several years in pots. Harvest by cutting off individual leaf blades to within 1 inch of the soil surface. Because chives make such slow growth from seed, it's best to buy a pot that's already established. Or divide and pot up a clump outdoors in the fall; leave the pot outside until the foliage has been killed back by frost, then bring the pot inside where it will make vigorous new growth.

Dill (*Anethum graveolens*): annual, to 3 ft. tall. Needs full sun; 6.0 optimum pH. Prefers daytime temperatures in the 60s and nighttime temperatures in the 50s, but can take temperatures in the mid-40s. Give plants room for good air circulation, and water whenever the soil surface begins to dry. Sow directly and thin to three seedlings per 6-in. pot or five per 8-in. pot; plants may need staking. Productive for two to four months indoors; harvest by cutting individual lower leaves once plant reaches 1 ft. tall. Dill is a difficult plant indoors. The best cultivars for pot culture are 'Aroma' and 'Bouquet.'

Garlic chives (*Allium tuberoosum*): perennial, to 2 ft. tall. Needs full sun; 6.0 optimum pH. Culture as for chives. A beautiful plant, with straplike, dark green foliage and dusters of pure white star-shaped flowers that smell like roses.

Ginger (*Zingiber officinale*): perennial, to 3 ft. tall. Needs shade. Ginger enjoys high temperatures, high humidity, and moist soil. Plant a fragment of rhizome—underground stem—with "eyes" on it in a roomy, shallow pot. When the rhizomes fill the pot, harvest by lifting them.

Marjoram (*Origanum Majorana*): perennial, to 1 ft. tall. Needs full sun; 6.9 optimum pH. Prefers daytime temperatures in the 70s and nighttime temperatures in the 60s, but can take temperatures in the high 40s. Marjoram needs good drainage and can be kept on the dry side. Allow plenty of room for air circulation. Cut plants back often to maintain bushy habit, as they are rapid growers. Potted plants remain productive for one to two years; after they become woody, root new 4-in. tip cuttings. Heavenly fragrance is pervasive—use sparingly in cooking.

Mints (*Mentha* spp.): perennial, to 2 ft. tall. Needs full or part sun; 6.5 optimum pH. Mints prefer daytime temperatures in the 60s and nighttime temperatures in the 50s, but can take temperatures in the low 40s. Give them good air circulation and high humidity, and water when the soil surface begins to dry. When crowded, repot into a container wider than it is deep, or divide into sections and pot each section. Mints remain productive for six months or more in pot culture. Harvest by trimming or cutting individual stems. Peppermint (*M. X piperita*), spearmint (*M. spicata*), and pineapple mint (*M. suaveolens* 'Variegata') make good pot plants.

Oregano (*Origanum vulgare*): perennial, to 1½ ft. tall. Needs full sun; 6.8 optimum pH. Prefers daytime temperatures in the 70s and nighttime temperatures in the 60s, but can take temperatures in the high 40s. Give plants good drainage and keep them on the dry side. Cut back often to contain spreading habit and improve air circulation. To ensure getting culinary oregano, buy plants or take 4-in. tip cuttings. Plants will remain productive in pots for one to two years. When they become woody, replace them.

Parsley (*Petroselinum crispum*): biennial, to 1½ ft. tall. Needs full or part sun; 6.0 optimum pH. Grows best between 60° and 65°F, but can take temperatures in the low 40s. Can be grown from seed; germination takes 9 to 21 days. Cover seed with ¼ in. of soil. Sow in late spring in a big container—a 3-gallon bucket is ideal. Set the pot outdoors and keep it watered until fall. Bring it indoors before the first fall frost,

Continued →

giving it cool temperatures and plenty of sun. Plant several to have plenty through spring. Harvest parsley by cutting the outer leaves, leaving the central rosette to produce new growth. The fine flavor of flat-leaf (Italian) parsley is stronger than that of curly parsley, but both make handsome pot plants. Parsley remains productive for six to nine months in pot culture.

Rosemary (*Rosmarinus officinalis*): perennial, to 6 ft. tall. Needs full or part sun; 6.8 optimum pH. Prefers daytime temperatures in the 70s and nighttime temperatures in the 60s, but can take temperatures in the low 40s. Don't let plants dry out completely or they'll die. Prune or pinch back frequently to maintain bushy habit. Propagate by 4-in. tip cuttings. Rosemary needs good drainage. If the needlelike evergreen leaves turn brown, the plant is being overwatered. Woody growth and yellowed leaves are signs that the plant is pot-bound.

Sage (*Salvia officinalis*): perennial, to 2½ ft. tall. Needs full sun; 6.4 optimum pH. Common culinary sage has spear-shaped, pungent, pebbly, gray-green foliage and blue flowers. Purple sage, with purple foliage; tricolor sage, with purple, white and green variegated foliage; and pineapple sage (*S. elegans*), with pineapple-scented foliage and red flower spikes, are also handsome pot plants. Sage must have good drainage but can withstand infrequent waterings. Prefers daytime temperatures in the 70s and nighttime temperatures in the 60s, but can take temperatures in the low 40s. Allow plenty of room for air circulation. Sage remains productive for one to two years in pots. Grow from tip cuttings. Prune regularly to maintain bushy shape. Be sure to have enough on hand for stuffing the Thanksgiving and Christmas turkeys!

Savory, winter (*Satureja montana*): perennial, to 1½ ft. tall. Needs full sun; 6.7 optimum pH. Winter savory prefers daytime temperatures in the 70s and nighttime temperatures in the 60s, but can take temperatures in the low 40s. Water when the soil surface begins to dry, and give plants plenty of room for air circulation. Prune regularly to keep plants productive. Winter savory will remain productive in pots for one to two years.

To wire with floral wire and corsage tape, first fold a piece of floral wire alongside the stem with the fold at the base of the flower head. Wind half of the wire around the stem to secure it. The second half of the wire remains long, to serve as the stem. Finish by wrapping corsage tape down the length of the wire, beginning at the flower head. Corsage tape will seal in place as you stretch and twirl it as you wrap. Be sure to cut wire stems to appropriate lengths so they will be held tightly in the base without protruding.

You can also glue flowers in place with either white craft glue that dries clear or hot glue. Nuts, berries, herbs, seedpods, and other materials may also be glued in place to accent your wreath.

Herbs as Houseplants

Claire Kowalchik and William H. Hylton

Herbs work hard as houseplants. They're not content to be merely decorative, like a fern or an ivy. In addition to good looks, herbs give you flavor, fragrance, or both. Running your hand over a piny rosemary or pungent, clove-scented thyme as you pass by can bring a room to life. And nibbling a leaf of fresh mint, basil, or chives can bring you to life.

Visually, there's an herb for every taste. Some are downright cute—a little mound of 'Spicy Globe' basil or a mat of fluffy lemon thyme covered with pink flowers. Others are more stately, like a potted bay shrub with its dark, glistening leaves and dignified carriage. Some, like spearmint, with its ramrod stems and crisp, toothed foliage, and chives, with its clump of tubular stems, are positively architectural. And then there are those like rosemary, with fuzzy, white, arching branches covered with dark evergreen, needlelike leaves, and parsley, with its mossy curls of foliage, which are simply beautiful.

But why grow herbs indoors? There are plenty of convincing reasons if "because I like them" isn't good enough. If you're an apartment dweller, your home is probably your garden. If you want to grow herbs well, there's no place like home. For those of us who live outside the Deep South, winter puts an end to outdoor herb growing but not to our craving for fresh herbs. The plants may go dormant until spring, but our taste buds don't! And some perennials simply wouldn't make it over the winter in most of the country. Bay, for example, is expensive, slow-growing, and very temperature-sensitive. Rosemary, lemon verbena, tricolor sage, marjoram, and scented geraniums are other finicky—but wonderful—herbs. Unless you have more money than sense, you'd be well advised to pot them up and bring them in over the winter or to grow these in pots year-round.

If you have some extra space and a fluorescent light setup, winter is also an ideal time to root cuttings for spring transplanting. You can increase your stock of lemon verbena, rosemary, lavender, thyme, and scented geraniums. By spring, you'll have the makings of a whole herb garden—or a border or edging. No need to wonder if the mail-order plants will arrive all right or if the local nursery has that cultivar you particularly like.

To simplify things, we can divide "houseplant" herbs into two categories: herbs grown indoors all year, which are basically decorative and fragrant plants, and herbs grown indoors in winter, which are usually food plants.

Herbs All Year

If you're going to have a plant in your house all the time, it's got to look good. And it helps if it's not too demanding. If you're going to grow herbs indoors and you want them to look good, you've got to stop thinking of them as herbs—for a minute, anyway. Think of them as houseplants. How will they look together? Do some make a particularly effective grouping? How will they look in flower? What are you going to put them in? And where are you going to put them?

The first rule of thumb is: If you're growing a plant for its ornamental appeal, it must look nice. One way to do this is to put them in an attractive container—a window box, ornamental tub, or planter box. Trailing varieties often look well in hanging baskets. Another technique is to plant them individually in similar containers. Groups of plain clay pots or dark Japanese-style planters are visually effective and focus attention on the plants—their colors, shapes, and textures—rather than on the container. Carefully chosen baskets can add another dimension of texture without distracting from the herbs. But if you've always wanted to plant herbs in that huge brass pot with nymphs and mermaids all over it, do it. Just put it in another place, so the spotlight is on the planter, not on the clash between the planter and the clay pots all around it.

Another way to play with herbs is to group them according to some unifying characteristic: herbs with white or blue flowers, gray-leaved herbs, fragrant herbs. It's better to mix herbs of different growth habits, rather than having a forest of tall herbs in one corner, trailing herbs on the sideboard and end tables, and a cluster of miniatures across the room on a table by themselves. Mixing lets you see more of the plants.

You can also train myrtle and some cultivars of scented geranium into standards: dwarf "trees" with a single "trunk." Myrtle and other herbs also lend themselves to topiary and espalier; however, before you start turning out thyme turtles, you'd do well to read up on the techniques and make sure you're willing to devote the time and care needed to maintain these high-tech plants. It would be good, too, if you prepared a spot to showcase the results.

There's one more thing to bear in mind: Potted plants don't have to stay indoors forever. You can move your bay, lemon verbena, and rosemary onto the patio for a summer breather, or sink them and your scented geraniums—pots and all—into the flower bed. They're a snap to unearth again in the fall, without root loss or transplant shock. Just make sure they haven't gained a few bugs before you bring them back inside!

Herbs in Winter

If you're growing herbs specifically for winter, chances are some of those herbs will be culinary herbs. You may be bringing in a clump of chives or a rosemary, or a spring-planted pot of parsley or ginger. Or you may be rooting cuttings of perennials like mint, sage, and oregano in midsummer for the winter windowsill. Or you may be sowing seeds of dill, basil, and marjoram in late August for the plant table. But a goal every gardening cook probably has in mind is: fresh herbs for winter salads, stir fries, and sauces, right at your fingertips.

When growing herbs for the winter kitchen garden, there's one cardinal rule: Make sure you grow enough. One perky little parsley or bright green basil may cheer you up on a snowy morning, but it is unlikely to go far toward perking up winter salads or spaghetti. Here's where a plant table comes in handy. Most herbs need strong sunlight to grow and produce well, and space at south-facing windows is usually at a premium. Setting up fluorescent lights over a shelf or table adds more growing space, so you can grow a more realistic number of high-use plants: parsley, basil, dill, chives, oregano, and the mints. If you enjoy cooking and don't have an attached greenhouse, a winter plant table is practically indispensable. And it lets you save the pretty plants—marjoram, thyme, rosemary, and lemon balm—for the windows!

Culture

Growing herbs indoors means dealing with seven major aspects of plant culture: light, temperature, air circulation, soil, fertilization, water, and pests. There are also the techniques for bringing plants in and propagation. Because herbs are less tolerant than most houseplants—they insist on conditions being "just so"—it helps to review their needs before heading out to the nursery or garden. Nobody wants a winter's worth of pale, spindly, spider-mite-infested herb plants.

Light: Most herbs thrive on light—at least five hours of direct sunlight a day. (Exceptions are the mints, bay, parsley, rosemary, thyme, myrtle, and santolina, which can take partial shade; and ginger and lemon balm, which actually like shade.) Natural sunlight can be supplemented or replaced with fluorescent light. A two-tube, cool white fixture hung 6 to 8 inches above the herbs and left on for 14 to 16 hours a day will keep your plants bushy and productive. You can maximize natural exposure by putting shelves in your south-facing windows, but don't crowd plants in or you'll have circulation problems.

Don't forget to turn the plants on windowsills regularly. Turning keeps the plants shapely and makes sure all sides get enough light.

Temperature: Most herbs like temperatures on the cool side—daytime temperatures of 65°F and night temperatures of 60° or even 55°F. Bay, dill, and the mints are the most insistent on daytime temperatures in the 60s and night drops to the 50s, and parsley does best between 60° and 65°F day and night. The other common household herbs do fine with daytime temperatures in the 70s and night lows in the 60s. If your house is cool, most herbs can survive temperatures in the mid- to low 40s (though scented geraniums and basil can't take it below 50°F). Obviously, foliage pressed against a frozen windowpane will

Continued ➔

LIGHT TABLE FOR HERBS IN WINTER

To make sure that windowsill plants get sufficient light, you can supplement the sun's energy with a fluorescent fixture mounted on wall brackets.

freeze and die. Move the plants away from the glass in freezing weather, or slip a sheet of paper between the plant and the pane.

Air circulation: Herbs are extremely sensitive to dry, stagnant air—the kind, unfortunately, in many tightly sealed, centrally heated houses. Stale air promotes fungal diseases and insect infestations. On the other hand, a blast of crisp winter air may be bracing to us, but it (or a constant draft) is anathema to herbs. Try to keep the air moving around the plants by cracking a window in an adjoining room or by opening doors for better cross-ventilation. Another preventive measure is to give the plants plenty of space so air can circulate around them. Don't crowd the pots, and don't let the foliage from neighboring plants touch! Finally, if the air is very dry, you can set the pots on pebble-lined trays filled with an inch or less of water. But make sure the pots are over—not in—the water.

Soil: Herbs in pots need a reasonably rich soil mix with good drainage. Some successful mixes are:

2 parts compost, 1 part vermiculite, and 1 part perlite

1 part sand and 1 part peat moss

1 part compost, 1 part sand, and 1 part perlite

7 parts loam, 3 parts peat moss, and 2 parts coarse sand

1 part potting soil, 1 part sand, and 1 part peat moss.

Experiment until you find a mix you're happy with. One word of warning: If you habitually have problems with plant diseases, you might be best off not using soil in your mixes. Or add sterilized soil if there's a source at hand.

On the subject of soil, be sure your plants have enough of it. No herb should be grown in a pot less than 4 inches in diameter; 6 inches is even better. For plants that spread by underground stems, like the mints and ginger, wide, shallow pots are ideal. And for herbs with long taproots, like bay and parsley, a deep pot or bucket is a necessity.

Fertilization: Fertilizing potted herbs involves a balancing act. You want to fertilize them enough to keep them productive but not so much that they get leggy and begin to lose their flavor. Once-a-month applications of seaweed or fish emulsion (which can smell pretty foul in a closed house, remember!) at half-strength should give them enough nutrients to keep growing.

Water: Herbs like regular waterings, but they're finicky. Waterlogged soil and pots standing in water tend to bring on root rot and other fungal diseases. Hence the need for a well-drained potting mix (leave the clay in the yard). Water most herbs thoroughly when the soil surface starts drying out. Let bay, marjoram, oregano, sage, and thyme dry out between waterings. But never let rosemary completely dry out—just one "dry spell" can kill it. The mints, lemon balm, ginger, and scented geraniums enjoy more moist conditions than their brethren. Always use room-temperature water so you don't shock the plants.

Pests: Herbs aren't attacked by pests often, but close, dry, indoor conditions can bring on infestations of spider mites, whiteflies, and aphids in succulent species, and scale on woody plants like bay, rosemary, and lemon verbena. Soap sprays can control spider mite, whitefly, and aphid attacks. To make such a spray, dissolve 1 to 2 tablespoons of a mild flaked soap like Ivory or Oxagon in 1 gallon of warm (not hot) water. Spray diligently once a week until the pests are brought under control. Be sure to coat the undersides of the foliage. Needless to say, wash the soapy residue off the leaves before adding them to food! Yellow sticky traps work well for whiteflies. Scale can be controlled by scraping off the insects or by daubing them weekly with alcohol-dipped cotton swabs. Isolate any infested plants, and if you can't control the infestation, get rid of them. This may seem drastic, but it's preferable to having an entire houseful of insect-ridden plants.

Bringing plants in: Perennial plants that won't survive the winter outside in most of the United States and Canada—rosemary, bay, lemon verbena, oregano, marjoram, camphor, and scented geraniums—must be brought indoors over the winter if they're to see another summer. Other perennials, such as chives, garlic chives, thyme, the mints, winter savory, and lavender, make the transition to indoor conditions fairly easily. When preparing to move plants inside for the winter, remember to acclimatize them first.

Dig the plants, causing as little root damage as possible, and pot them carefully. Then water the herbs and set them in a shady place outdoors for three days to a week so they can gradually adjust to the dual shocks of pot culture and decreased sunlight. Check the plants vigilantly for pests, and isolate them for a couple of weeks before mixing them in with your other houseplants, just in case an infestation has slipped by you. This

shading-and-checking routine is necessary even when moving in plants that have spent the summer outdoors in their pots, like bay, rosemary, parsley, and lemon verbena.

The best time to pot most outdoor herbs is after the fall harvest and before the first frost. They should be safely indoors by the time frost strikes. Chives and garlic chives, however, benefit from induced dormancy before "coming in from the cold." Divide the clumps, pot them, and let them remain outside until frost kills the foliage. Then bring them in for a new burst of lush, stocky growth.

Propagation: Start annual seeds (such as basil and dill) as well as parsley and perennials that will come true from seed (marjoram and thyme, for example) in the same mix you plan to pot them in. Sow the seed in late August or early September, water the flats, cover them with plastic wrap, and put them where temperatures will drop no lower than 60°F. (The top of the refrigerator is warm and out of the way.) When the seeds sprout, remove the plastic and move the flats into full sun. Keep the soil moist but not soggy. When seedlings have their second set of true leaves, transplant them to 4-inch pots, and when the first pots are outgrown, move the plants to 6-inch pots.

For cultivars that will not come true from seed or herbs like lemon balm that are difficult to germinate, start with plants or take cuttings. Rosemary, the mints, thyme, lavender, lemon verbena, scented geraniums, culinary oregano, and sage can be propagated by taking 4-inch tip cuttings, stripping off the lower leaves and sticking the stems in moist perlite. Take the cuttings two to three weeks before the first fall frost (or earlier; they take two to three months to root). If your home has especially low humidity, you can cover the flats with glass or plastic to promote higher moisture levels. Again, be sure to keep the perlite moist but not soggy.

Barbara W. Ellis

Growing Vegetables in Containers

Container gardening is more popular today than ever—and for good reason. It is a boon for apartment dwellers, a necessity for rooftop gardeners, and just plain fun even for those of us blessed with ample garden space. Raising flowering plants in containers has long been a favorite activity, and more and more gardeners are discovering the challenges and rewards of container vegetable gardening.

Vegetables and flowers can readily be grown in tubs, crocks, pots, barrels, sacks, baskets—nearly any vessel that is nontoxic and large enough to accommodate the plants and allow sufficient drainage. Containers may be decorative—half-barrels and wood planting tubs are both popular—or strictly practical. Some containers are especially designed for vegetable growing.

You can make a simple container by slitting plastic bags of soil mix and setting transplants directly into the bag. Or consider recycling baby bathtubs, leaky buckets, plastic milk jugs, and other containers that otherwise would help to clog a landfill. Whatever you choose, be sure there are holes in the bottom so that excess water drains away. Otherwise, your plants can easily become waterlogged and drown. Drainage holes also are important for flushing water through the soil to dissolve accumulated salts.

Almost any vegetable can be grown in containers, but the most popular are the salad vegetables, including lettuce, radishes, onions, cucumbers, and peppers. Carrots, beets, and other root crops will do well in containers as long as you provide sufficient rooting space. Cucumbers are particularly suited to hanging baskets; peppers and eggplant can be interplanted with flowering annuals. In response to the increasing popularity of container gardening, breeders have developed dwarf or compact cultivars of most common vegetables. Even watermelons can now be raised in 5-gallon containers.

Herbs grow well in smaller containers. Parsley and thyme are well suited for hanging baskets, where they may be interplanted with flowering annuals. Two-gallon tubs or baskets are large enough to support vigorously growing perennial herbs such as mint and rosemary. Eight- to 12-inch pots are sufficient for basil and lavender. And even 4- to 6-inch pots will support chives, dill, parsley, and thyme. A box planter under the kitchen window is a convenient place to grow chives, parsley, and other low-growing herbs so you can snip quickly while cooking.

A word to the wise: Be sure to pick a container that will be large enough to handle the mature plant. Transplanting can stress a plant, which will affect your harvest. Again, be sure that your containers have drainage holes.

KEYS TO SUCCESS

The keys to successful container vegetable growing are a good soil mix, adequate soil moisture, and a steady nutrient supply, along with some good basic gardening practices.

Soil

The soil mix should be light, airy, capable of holding moisture and nutrients, yet quick to drain. A common mixture is 1 part potting soil, 1 part compost, and 1 part sharp sand, with a

Continued →

little added bonemeal. A more expensive variation of this mix substitutes vermiculite for the sand, producing a mix that weighs less but holds more moisture.

Water

Adequate soil moisture is critical. Summer heat dries soil mix in containers rapidly. Soil in wood and unglazed clay containers dries out more quickly than that in plastic or other nonporous containers. If your area has intensely hot summers, don't use dark-colored containers, which absorb heat more readily than those made of light-colored materials. Wooden containers have an insulating effect and may help to keep roots cooler.

In general, you'll need to water all container plants daily in hot weather, not only to keep roots moist, but to help cool your plants and wash away accumulated salts.

Food

Vegetables in containers need more frequent feeding than those grown in the open garden. The most popular fertilizer is ordinary fish emulsion, although liquid seaweed is also suitable. Mix according to label directions and apply once a week. You can also feed container vegetables with homemade manure tea.

Training Standards

Visitors to formal gardens are often impressed upon seeing container-grown roses, geraniums, lantanas (*Lantana* spp.), and other woody shrubs that have been specially trained into treelike forms called standards. You can train standards for your own garden and enjoy them indoors or out, all year around, depending on your climate. The training takes patience and care, but is by no means a task for experts only.

The perfect candidate to be trained as a standard is a fast-growing woody shrub that produces many small-sized leaves. If the shrub blooms freely, so much the better. Geraniums, roses, and lantanas are often trained into standards. But there are many other candidates—figs (*Ficus* spp.), fuchsias (*Fuchsia* spp.), citrus trees (*Citrus* spp.)—nearly any woody shrub that appeals to you. Even woody herbs such as lavender (*Lavandula* spp.), sweet bay (*Laurus nobilis*), and rosemary (*Rosmarinus officinalis*) may be trained to tree form. Plants with small leaves are best because when the standard has grown to 3 to 4 feet in height, the crown of small leaves atop the single "trunk" helps to create the impression of a real tree in miniature.

Standards can be grown in garden beds, but container growing is preferred because the plants can then be moved indoors or outside, depending on the season, the weather, and the hardiness of the plant. Some standards are produced by grafting compatible plants—a favorite tea rose scion grafted or budded onto a *Rosa multiflora* rootstock, for example. The following directions are for turning an ordinary shrub into a miniature tree, without grafting.

STEPS FOR TRAINING

1. Start your standard with a small, rooted cutting, but choose a strong and straight one. You may also use a small plant if it has a single, strong leader that is growing upward. Plant it into a 3-inch pot and begin the training immediately.
2. Insert a 10-inch stake next to the plant to train the leader to grow perfectly vertical. Tie the main stem to the stake using soft cord, and remove any side shoots that appear.
3. As the leader grows, continue to tie it every 2 to 3 inches—or even more closely if it threatens to stray. Continue removing any side shoots that appear. Leaves that grow directly from the leader may be kept temporarily, since they help to manufacture food for the plant's growth. They will be removed after the tree is trained.

4. When the plant reaches about 12 inches in height, transplant it to a larger pot, if necessary, and insert a new stake that will be nearly as tall as the eventual height of the standard. Continue to grow the plant in this manner, repotting as necessary when the plant becomes rootbound, until it reaches the desired height.
5. When it has grown as tall as you wish, stop the plant's vertical growth by pinching the terminal bud. This will force the growth of lateral branches. Allow these to grow for about an inch, then pinch these back, also, to encourage still more lateral branches to form. By encouraging lateral branching and removing side shoots from the trunk, you are forcing the plant to form a globular head or top.
6. To maintain the standard at the desired height and shape, you'll need to pinch and prune it regularly. In several years, the main trunk or stem will become thick and sturdy enough so that the supporting stake can be removed.
7. For continued health, be sure to meet all the other requirements—light, humidity, temperature, seasonal rest—of the species you have chosen.

Creating a Tub Garden

If a full-sized lily pond is not in your immediate gardening future, you can at least experience a bit of the aquatic gardening world with a tub garden of your very own. Lily ponds are certainly lovely, but tub gardens also have advantages. They're easy to set up and maintain, may be moved about if necessary, and can be used on porches, patios, decks, and terraces. Be sure to pick a site in full sun—at least five hours of direct sun daily—for best bloom of water lilies.

GETTING STARTED

Almost any large container at least 20 inches deep and 12 inches wide may be used for a tub garden, as long as it is watertight. If you have an attractive container that is not watertight, then look for a suitable plastic liner. Wooden half-barrels are commonly used for tub gardens, as are large ceramic tubs. If you choose to sink the container into the ground, then, of course, outward appearance is not important. Be sure that there are no residues of toxic substances in the container you choose. Wooden half-barrels used for aging whiskey can be toxic to fish. Fresh barrels will smell of whiskey. Age them several months until they no longer smell before you try adding fish or plants.

Selecting Plants for Tub Gardens

Water lilies (*Nymphaea* spp.) are the most popular plants for tub gardens. Since water lilies need ample growing space, most tubs are capable of handling no more than one full-sized plant. Your best bet is one of the dwarf water lilies; that way, you'll have room for one or more of the fascinating bog plants available. For visual interest, consider adding a plant that will provide a vertical accent. For the latter, consider pickerel weed (*Pontederia cordata*), bog rush (*Juncus effusus*), elephant's-ear (*Colocasia* spp.), or arrowhead (*Sagittaria* spp.). Water poppy (*Hydrocleys nymphoides*) is a floating-leaved plant with showy yellow flowers. European water clover (*Marsilea quadrifolia*) has bright green, floating leaves shaped like four-leaf clovers. Other aquatic plants may be found in mail-order water garden catalogs.

To provide clear water and a proper habitat for fish, each tub should have at least one pot of submerged oxygenating plants, such as elodea (Elodea spp.) or hornwort (*Ceratophyllum demersum*).

Potting Plants

Once you've selected the container for your tub garden and chosen a site in full sun, you're ready to pot up your plants. It's best to pot the plants and set them in place before filling the tub with water. Wait a week or two for the plants to become established before introducing fish.

Each plant should be grown in its own pot. In this case, it's not necessary to use pots with holes in the bottom; plastic dish tubs are ideal. The best soil for tub plants is ordinary garden loam that has been sieved to remove rocks, pieces of roots, and other organic matter. Manure, compost, peat moss, and raw organic matter such as roots or leaves will foul the water.

Position the roots and fill the containers. Leave enough room at the top of the pot for a 2-inch layer of pea gravel on the surface of the soil. This will help keep the water clear and discourage fish from digging in the soil and muddying the water.

Filling the Tub

Set the plants in place in the tub. The amount of water that should cover the pots varies from plant to plant. Pots of oxygenating plants rest on the bottom. Full-sized water lilies can rest on the bottom, generally. Miniatures or bog plants must be positioned closer to the surface. Use bricks under pots to adjust them to the proper depth. Then fill the tub slowly by trickling in water.

It will take a few weeks for your tub to become balanced. Once the soil has settled to the bottom and the plants begin to grow, the water should clear. If the water turns very green before the plants have had a chance to grow, empty the tub and refill it. Once the leaves of water lilies and other floating-leaved plants appear, they will shade the water. This will not only keep it cool during the hot summer months, but will also help reduce free-swimming algae in the water. Plants and fish prefer water temperatures in the 65° to 75°F range. When you are ready to introduce fish, float them on the surface of the water in a water-filled plastic bag for an hour to equalize the temperature, before opening the bag and releasing them. (Remove fish immediately if they begin gulping air at the surface.)

In the fall, unless you live in an area where temperatures do not fall below freezing, you'll need to drain and clean the tub.

Continued ➔

Fish can be moved indoors into an aquarium or other container; goldfish can be kept through the winter at temperatures between 40° and 45°F. Tropical lilies grown in temperate climates are best discarded at this time. Hardy lily tubers may be stored in moist sand over winter and replanted the following sprmg.

Making Mix and Choosing Containers

Fern Marshall Bradley

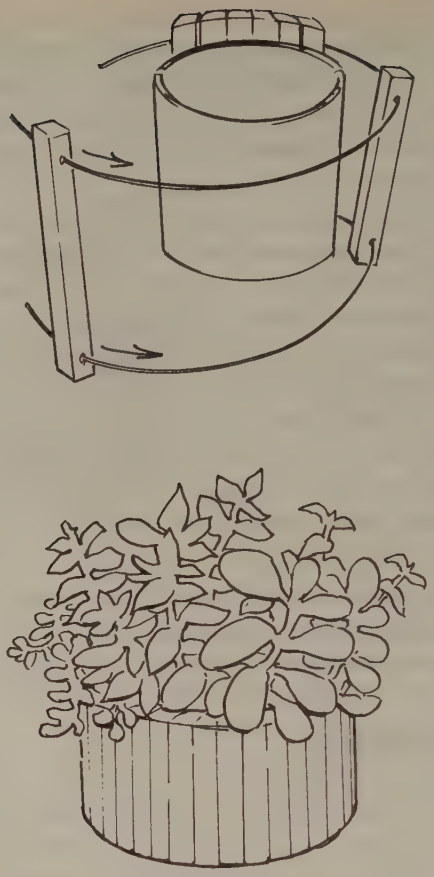
After you've decided what plants you want to grow, your first priority is choosing the right containers and potting soil. You can match your containers to your house style, personal taste, or the type of plant you're growing. (For example, a tropical-looking bamboo or vine would look at home in a wicker basket.) You'll be amazed at the variety of containers available—from standard clay and plastic to half-barrels and "found objects" like old teapots or watering cans. Here are some great tips for finding or making good soil mixes and containers.

Do You Have Soil Savvy?

If your garden soil produces luscious tomatoes or stunning roses, you may wonder whether it would work just as well for your potted plants. Definitely not, says Rita Buchanan, a Connecticut garden writer. "I think one of the most common mistakes container gardeners make is digging up soil from the garden and putting it in a pot," she says. "A pot is so little compared to the garden—moisture just doesn't drain through a pot like it does in the ground." That means you need a soil that won't pack down too easily or stay wet too long. Buy a commercial potting soil mix or make your own. Buchanan suggests mixing equivalent amounts of loamy garden soil, screened compost or peat moss, and perlite or coarse sand.

Coarse Mix Is Fine for Pots

Check the heft on that bag of potting mix before you lug the sack home. Jim Wilson, a cohost of public television's *The Victory Garden*, feels that the single most important thing about growing plants in containers is using a coarse-textured growing mix and avoiding dense, heavy potting soil. Wilson suggests that when you're buying potting soil in retail outlets you judge bags of similar volume by weight, because the label usually provides little information about contents. (Potting mixes don't have to list ingredients.) "If the bag is heavy, don't buy it," he says. "Some mixes contain sand to add weight, so you'll think you're getting more; if it's river sand of varying particle size, it just packs down in the pot. The other thing to watch for is bags where the soil is [made] wet to make it heavier and give it a rich, black color."



Plastic pots are unquestionably useful because they're lightweight and reusable. But they don't make much of a show on the patio or deck. One alternative to repotting in a decorative container is to hide the plastic pot in an attractive "cover-up." This handsome wooden pot is really a shell of 1 x 1's. To make one, cut the 1 x 1's to the right length to cover your pot. Drill holes through each piece about 1 inch from the top and bottom, as shown. String the pieces together with copper wire.

Pick a Perfect Pot

Not all containers are created equal—that's the word from Holly H. Shimizu, the acting assistant executive director at the U.S. Botanical Garden in Washington, D.C. If you're trying to decide which kind of container to use, she suggests keeping these points in mind:

- Clay and terra-cotta pots are porous, so you'll probably need to water plants in them more often than if you used plastic containers. But soil in these types of pots stays cooler than in plastic—a benefit in sunny sites and hot weather.
- Plastic pots hold heat and water better than clay pots. They're also lighter and less expensive, but they have a tendency to crack or break with age.
- Stone and concrete containers are extremely durable, but they're very heavy and relatively expensive.

Whatever kind of pot you choose, remember that any container used for plants should have holes for adequate drainage. Shimizu says that using old pots is fine, as long as you care for them properly. "When you recycle your pots, it's very important to make sure they're clean. A lot of people neglect to do that—and the pots can carry diseases that way," she says. She recommends removing old soil and plant debris, soaking the pot in water, then scrubbing it with a mild liquid detergent. Rinse the pot thoroughly, and dry it. Your container is now ready for a new plant!

Continuing Care

Choosing a pot and potting soil mix gives your plants a good start, but you can't stop there. Container plants need ongoing care—watering, feeding, grooming, watching for signs of pests and diseases, and if they stay outdoors all year, winterizing. Surprisingly, the biggest hurdle for most plant owners is watering. Here are some expert tips and tricks for handling watering and other routine chores.

Help! They Can't Swim!

Overwatering is the number one problem in container gardening, according to Tovah Martin, the staff horticulturist at Logee's Greenhouses in Connecticut. "When you're living with a plant intimately, you tend to baby it, and that usually means watering it too frequently," she says. "You have to remember that the soil does not go down to China." When you overwater, you are actually suffocating the roots, which can eventually die from lack of oxygen.

So when should you water? "When the soil is dry to the touch," says Martin. She suggests sticking your finger about ½ to 1 inch down into the soil; if it feels dry, it's time to get out the watering can. Don't let the soil become parched, however. If it gets too dry, it won't be able to absorb moisture, and the water will simply run down the sides of the container.

Sometimes the plant itself is your best moisture barometer. Martin lets her plants go into a slight wilt before watering them. "It usually does no harm to let plants wilt slightly," she says. "As a matter of fact, with many plants, such as bougainvilleas, it will promote bud formation."

How much water is enough? Martin recommends leaving about ¼ to ½ inch between the soil surface and the rim of the container when you're potting a plant. Then, each time you water, fill the pot to the rim once. Don't succumb to the temptation to refill it again and again, or you'll drown the roots.

The Root of the Problem

When's the last time you looked at the roots of your potted plants? The last time you repotted them? Never? If your plants are looking peaked, inspect their root balls. Taking your plants out of their pots from time to time to inspect the roots won't hurt them. Simply turn the pots upside down and gently lift the plants out. If the roots look bright and shiny, you'll know they're healthy. But if they look soft, rotted, or discolored or if they smell bad, that's a sign of trouble. Cut away diseased or discolored roots and repot in a sterile soil mix.

Put Panty Hose in Your Pots

Old panty hose can be part of a handy system for watering houseplants and hanging baskets. Some houseplants, such as African violets, wood sorrels, and ferns, need more water than others. If you have trouble remembering to make those extra watering trips, try using a hidden water reservoir for passive irrigation. Barbara W. Ellis, the managing editor of garden books for Rodale Press, has rigged up a system using a plastic freezer container under each extra-thirsty plant in her office. She pots up the houseplant in a shallow container, such as an azalea pot or bulb pan, that has a 1-inch-wide strip of panty hose inserted through the bottom drainage hole. The panty hose strip hangs down into the freezer container and wicks water up to the soil mix. She conceals the whole setup inside a larger decorative pot. "It's a really convenient system for plants that need more frequent watering," says Ellis.

Rocks in Your Pots?

Contrary to what some gardeners may think, putting a layer of gravel or other similar material in the bottom of a container does not improve drainage. In fact, it can decrease plant growth, since the space occupied by rocks could hold soil and roots instead.

There is still a valid reason for putting rocks in pots, however: Pebbles, rocks, gravel, stone chips, or broken pottery can keep pots from blowing over.

Winterizing Potted Trees

If you garden in the North, take special precautions to make sure your hardy containerized trees and shrubs survive the winter outdoors. According to Christina R. J. Pey, a supervisor

Selecting Plants for Container Gardens

Container gardening is a great way to brighten up a deck or patio—or just a corner of your backyard where you're tight on space. Any of the following plants will thrive in containers such as tubs, old wheelbarrows, pots, urns, troughs, sinks, or hanging baskets—just make sure there are holes for adequate drainage. Position your container before you fill it—it may be too heavy to move later. It is very important to feed and water plants regularly. After a couple of months in their containers, plants will need about a pint of liquid fertilizer, like manure tea or fish emulsion, every two weeks during the summer.

Name	Height	Description	Culture
Achimenes spp. (Achimenes)	8–12 in.	Flowering African violet relatives with scaly rhizomes and flat-faced, tubular flowers in pink, blue, purple, red, orange, yellow, or white. Blooms spring to frost.	Tender perennial usually grown as an annual from scaly rhizomes. Partial to deep shade. Light, well-drained soil rich in organic matter. Water and feed heavily. Propagate by division, cuttings, seeds. Rhizomes can be dried and overwintered indoors.
Begonia X *semperflorens-cultorum* hybrids (Wax begonia)	6–12 in.	Compact, fleshy plants with waxy single or double flowers that are pink, red, or white. Foliage is fleshy and green, maroon, or bronze. Blooms spring to frost.	Tender perennial usually grown as an annual. Full sun to partial shade. Moist, well-drained soil rich in organic matter. Best propagated by cuttings. Or sow seed indoors 12–14 weeks before last frost. Almost continuous bloom. Can be brought indoors in fall and overwintered as a houseplant.
Browallia speciosa (Browallia)	12–15 in.	Attractive plant with bell-shaped flowers in blue or white. Leaves are narrow and dark green. Blooms spring to frost.	Tender perennial usually grown as an annual. Full sun to partial shade. Moist, well-drained soil rich in organic matter. Propagate by cuttings or sow seed indoors 6–8 weeks before last frost. Can be brought indoors in fall and overwintered as a houseplant. Attractive when combined with other annuals.
Caladium spp. (Caladium)	9–30 in.	Genus grown for its showy, many-colored leaves marked and patterned in combinations of white, pink, red, or green.	Tender perennial grown as summer-flowering bulb from tuber-corms. Partial to deep shade. Moist, well-drained soil rich in organic matter. Remove flowers as they appear. Propagate by division. Hardy only in Zone 10; dig tuber-corms and store in a cool, dry spot over winter. Many cultivars available.
Calendula officinalis (Pot marigold)	6–24 in.	Daisy-family member with yellow, cream, white, or orange daisylike flowers and bright green leaves. Blooms spring to frost.	Annual. Full sun to partial shade. Rich moist soil. Sow seeds in the containers where the plants are to grow. Excellent cut flower. Best where summers are cool.
Catharanthus roseus (Rose periwinkle)	18–24 in.	Low-growing, summer-blooming plant with showy, flat-faced flowers in white, rose, pink, or mauve. Leaves are glossy green. Sometimes sold as *Vinca rosea*.	Tender perennial usually grown as an annual. Full sun to partial shade. Will tolerate most soils, including dry ones. Hardy in Zone 10. Prefers warm temperatures.
Celosia cristata (Cockscomb)	6–36 in.	Unique-looking, summer-flowering annual with crested or plumed flower heads in yellow, orange, red, and purple.	Annual. Full sun. Sandy, well-drained soil rich in organic matter. Sow seeds indoors 4–6 weeks before last frost, or sow outdoors. Good cut flower. Blooms can also be dried. Attractive when combined with other annuals.
Chrysanthemum X *morifolium* (Hardy chrysanthemum)	12–48 in.	Popular, fall-blooming perennial with yellow, purple, scarlet, orange, pink, or white daisylike flowers that may be single or double.	Hardy perennial. Full sun to partial shade. Rich to average, moist, well-drained soil. Pinch back stems in early part of season to encourage branching. Zones 3–10; often grown as annual. Good cut flower. Many reclassified as *Tanacetum* or *Leucanthemum*.
Coleus X *hybridus* (Coleus, flame nettle)	6–36 in.	Shrubby plant grown for its ornamental foliage, which is variegated in combinations of chartreuse, white, bronze, gold, copper, yellow, pink, red, purple or green.	Tender perennial usually grown as an annual. Full sun to partial shade. Moist, well-drained soil rich in organic matter. Propagate by cuttings, seeds. Pinch off flowers as they form. Can be brought indoors in fall and overwintered as a houseplant. Excellent plant to add color to a shady spot.
Crocus spp. (Crocus)	3–6 in.	Early spring-blooming plants with purple, lilac, blue, cream, yellow, white, or orange chalice-shaped flowers and grassy leaves.	Hardy perennial grown from a corm. Full sun to partial shade. Sandy or gritty, well-drained soil. Propagate by cormels, seeds. Zones 3–8. Useful for adding spring color to large containers that remain unplanted during winter.
Hemerocallis hybrids (Daylily)	12–48 in.	Summer-blooming, clump-forming plants with sword-shaped leaves and trumpet-shaped flowers in yellow, orange, red, pink, or lavender. Each bloom opens for only a day.	Hardy perennial. Full sun to partial shade. Moist, well-drained soil rich in organic matter. Propagate by division. Zones 3–8. Many cultivars available; miniature selections are especially effective in containers.

Hosta spp. (Plantain lily)	6–36 in.	Sturdy, clump-forming perennials grown for their attractive foliage, which may be blue-green, green, or patterned with yellow and/or white. Spikes of violet or white, bell-shaped flowers produced in summer or fall.	Hardy perennial. Partial to deep shade. Moist, well-drained soil rich in organic matter. Propagate by division. Zones 4–9. Many cultivars available. Underplant with crocuses or daffodils for spring color.
Impatiens wallerana (Busy Lizzy, patient Lucy)	6–30 in.	Mound-shaped, fleshy plant covered with single or double flowers of white, pink, orange, salmon, red, or lavender. Flowers may be a solid color or bicolor. Blooms appear spring to frost.	Tender perennial usually grown as an annual. Partial to dense shade. Moist, well-drained soil rich in organic matter. Prefers warm weather. Can be brought indoors in fall and overwintered as a houseplant.
Lantana camara (Yellow sage)	12–36 in.	Shrubby plant with many clusters of tiny flowers that are usually yellow or pink on opening and change to red, orange, or lavender. Blooms appear spring to frost.	Tender shrub usually grown as an annual. Full sun. Rich, loamy, well-drained soil. Propagate by softwood cuttings. Seed takes 8 weeks to germinate; sow indoors 12–14 weeks before last frost. Zones 8–10; has become a weed in areas where it is hardy. Can be brought indoors in fall and overwintered as a houseplant.
Lobelia erinus (Edging lobelia)	4–8 in.	Trailing, summer-blooming annual with many small fan-shaped flowers in deep blue, pale blue, red, or white.	Annual. Full sun to partial shade. Rich, sandy, moist soil. Sow seed indoors 10–12 weeks before last frost; do not cover, seed requires light for germination. Pinch plants to promote bushiness. Attractive when combined with other annuals.
Lobularia maritime (Sweet alyssum)	6–12 in.	Ground-hugging, spring- to summer-blooming plant with abundant clusters of fragrant white, pink, or purple flowers.	Perennial usually grown as an annual. Full sun. Average well-drained soil. Shear back plants occasionally to encourage repeat bloom. Can be brought indoors in winter for further bloom. Attractive when combined with other annuals.
Muscari spp. (Grape hyacinth)	8–12 in.	Low-growing, spring-blooming bulbs with dense grapelike clusters of bluish purple or white, bell-shaped flowers. Grasslike leaves.	Hardy bulb. Full sun to partial shade. Sandy, well-drained soil rich in organic matter. Zones 5–8. Good for cutting. Many cultivars available. Useful for adding spring color to large containers that remain unplanted during winter.
Nicotiana alata (Flowering tobacco)	18–30 in.	Summer-flowering plant with white, lime, lavender, pink, or red, trumpet-shaped flowers that are very fragrant at night.	Full sun to partial shade. Moist, well-drained soil rich in organic matter. Sow seed indoors 6–8 weeks before last frost.
Pelargonium spp. (Geranium)	12–36 in.	Large genus grown for ornamental flowers and/or foliage. Bedding or zonal geraniums grown for their 3–5-in.-wide flower clusters in pink, salmon, red, or white. Other species grown for their scented foliage. Blooms appear spring to frost.	Tender, shrubby perennial usually grown as annual. Full sun. Loamy to sandy, well-drained soil rich in organic matter. Propagate by cuttings. Remove flowers as they fade. Hardy in Zone 10; can be brought indoors in fall and overwintered as a houseplant. Many cultivars available.
Petunia spp. (Petunia)	10–18 in.	Popular, sprawling annuals with trumpet-shaped blooms in many forms and colors. Blooms may be violet, pink, salmon, rose, red, yellow, or white, either solid colors or bicolors. Blooms may be single or double and appear spring to frost.	Full sun. Rich, light, sandy soil with very good drainage. Pinch branch tips after first flush of bloom to encourage branching. Attractive when combined with other annuals.
Portulaca grandiflora (Rose moss)	4–8 in.	Fleshy, mat-forming plant with red, gold, yellow, cream, rose, white, or salmon flowers that open in sunny weather. Blooms appear spring to frost.	Annual. Full sun. Sandy, dry, well-drained soil. Withstands heat, drought. Attractive when combined with other annuals.
Thunbergia alata (Black-eyed Susan vine)	48–120 in.	Vining plant with orange, buff, or apricot flowers that have a purple or black throat and dense, dark green leaves. Blooms appear spring to frost.	Tender perennial usually grown as an annual. Full sun to partial shade. Light rich, moist, well-drained soil. Provide a trellis or allow to trail over edges of pot or hanging basket. Sow seed indoors 6–8 weeks before last frost.
Tulipa spp. (Tulip)	6–30 in.	Popular spring-blooming plants with cup-shaped blooms in many colors including red, yellow, pink, white, maroon, and orange.	Hardy bulb. Full sun. Sandy, well-drained soil rich in organic matter. Propagate by offsets. Zones 2–9. Can be grown as an annual, or, when leaves yellow, lift and store bulbs in a cool, dry spot and replant outdoors in fall. Useful for adding spring color to large containers that remain unplanted during winter.
Viola spp. (Violet, pansy)	4–6 in.	Attractive, spring-to-summer blooming plants with purple, blue, red, yellow, white, or ivory flowers. Many are bicolored with large, facelike patches.	Annual and perennial species. Full sun to partial shade. Moist, rich soil. Best in areas with cool summers. Pinch back plants in midsummer to encourage further bloom. Mulch in summer to keep soil moist and cool. Good for adding early spring color to containers left outdoors; attractive when combined with other annuals.

for the production greenhouses at the Missouri Botanical Garden, the most important thing is to check the size of the plant's root ball. "If the root ball is almost touching the container sides, chances are the plant will be affected by the cold and may even die," says Pey.

If the roots of any of your trees or shrubs are too near the sides of their container, consider moving the plant to a larger pot. If your plant is already in as large a pot as you want or have room for, you can prune the roots back. (When you root-prune, prune the top growth in the same proportion.)

Another way to winterize container-grown trees and shrubs is to move them to a protected site—against the side of a building or in a garage that gets lots of light. Clumping your plants together also provides protection against the cold. For larger containers that can't easily be moved, Pey suggests piling mulch up around them.

Tropicals Take the Heat

Temperature has a critical effect on growth of tropical plants in containers indoors. Fred Saleet, the owner of The Banana Tree, a Pennsylvania company that specializes in uncommon tropical seeds, recommends the following temperature regimes:

- *Heloconia* spp. (heliconias): daytime—80°F or higher; nighttime—not below 70°F
- *Musa* spp. (bananas): daytime—75°F or higher; nighttime—at least 67°F
- *Strelitzia* spp. (bird-of-paradise): daytime—80°F or higher; nighttime—not below 68°F
- *Theobroma cacao* (chocolate-tree): daytime and nighttime—at least 70°F

Keep in mind that temperature requirements vary according to which species you're growing.

Creative Containers

Containers aren't just for houseplants or annual flowers. You can grow dwarf fruit trees, shrubs, flowering perennials and bulbs, ornamental grasses, vines, and just about any other plant in a container. You can have a container vegetable garden, herb garden—even water garden. So stretch your limits, and try something different. Here, the experts offer us some ideas for branching out into new areas with container gardening.

Theme Gardens, Container-Style

The sky's the limit when it comes to container garden ideas. For something a bit out of the ordinary, try a garden with a lemon-fragrance theme, like the one on display one summer at the U.S. Botanic Garden in Washington, D.C. "All of the plants had some lemon flavor or golden flowers," says Holly H. Shimizu, the acting assistant executive director at the U.S. Botanic Garden. To start a similar container garden of your own, she suggests planting lemon-scented marigolds (*Tagetes tenuifolia*), golden lemon thyme (*Thymus* X *citriodorus* 'Aureus'), lemongrass (*Cymbopogon citratus*), lemon balm (*Melissa officinalis*), and lemon basil (*Ocimum basilicum* 'Citriodorum'). Don't forget lemon-scented geraniums (*Pelargonium crispum*), including 'Prince Rupert' and 'Mabel Gray,' "the most lemony of all," according to Shimizu. "It's so lemony, your mouth waters," she says.

If a more formal design appeals to you, try a container knot garden. Shimizu recommends a figure eight composed of clipped fragrant herbs and topiary—for example, silver and golden thyme to form the eight and a myrtle (*Myrtus communis*) topiary to fill the center of each of the circles. "The topiaries we used in our display had twisted stems and round heads, like lollipops," she says. "You can use any number of complementary plants—any other kind of topiary, if you want height, or another little filler in the middle of the eight. It depends on whether you like the open look or the closed look."

Try These Four Tropicals

If you're thinking about growing exotic plants indoors, you'll need to tend to their needs year-round, says Fred Saleet. According to Saleet, four tropical plants that are relatively easy to grow and have the same general cultural requirements are bananas (*Musa* spp.), cacao or chocolate-tree (*Theobroma cacao*), the exotic bird-of-paradise (*Strelitzia* spp.), and heliconias (*Heliconia* spp.)

My, How Small You've Grown!

The next time you start a bonsai, plant a seedling of the same species in the ground at the same time. Within a few years, you'll be amazed at the difference in size between your miniature containerized specimen and that shady tree outside.

Top Ten Herbs to Grow Indoors

Here are ten herbs that are excellent for indoor growing, recommended by Christina R. J. Pey, a supervisor for the production greenhouses at the Missouri Botanical Garden:

Basil	Oregano
Dill	Parsley
Fennel	Sage
Marjoram	Tarragon
Mint	Thyme

All four of these plants need a combination of warmth, bright light, and high humidity—and not just when it's sunny and warm outside. Says Saleet, "Many people grow them very well in the spring and summer. Then, in the winter, they ask, 'Why is it dying? It was growing so well!' " He suggests using a high-intensity light (100 watts or higher) when the weather turns dark and cold. "You want consistency in the climatic conditions," he says. "You don't want a break in the action."

Keep in mind that these tropical plants, particularly the banana, also require frequent fertilization. "If a plant is pushing out one flower after another, that means it's in need of a supply of nutrients," says Saleet. Don't make the mistake of fertilizing the plant if it looks sick, however. Although there's a chance that it's suffering from nutrient deficiency, more than likely there's something else, such as spider mites infestation, that's causing the problem.

Double Your Bulbs, Double Your Bloom

Ever wonder how exhibitors at flower shows get so many tulips or daffodils to bloom in one container? "The bulbs are planted one on top of the other," says Raymond J. Rogers, the garden editor for Dorling Kindersley in New York. "That's why the pots look like they're jam-packed—they are jam-packed." When the bulbs bloom, you'll have a pot that's bursting with color—a real showstopper on a gray winter day.

According to Rogers, who has won many awards for his bulb entries at the Philadelphia Flower Show, it's best to start with a soil mix composed of 2 parts good garden soil, 2 parts potting mix, 1 part perlite, and 1 part #3 grade (coarse) sand. Here's the method.

1. Put the soil mix in the bottom one-third of the pot, then put in a layer of bulbs pointed-side-up. (How much mix you add depends on bulb size. For example, plant long-necked daffodils deeper than short-necked daffodils.)
2. Add mix until the tops of the bulbs just poke through the surface, then position a second layer of bulbs in between the tops of the first layer.
3. Add another layer of mix until you can barely see the tops of the bulbs poking through.

This method works best with tulips and daffodils, though some people have had success planting reticulated iris (*Iris reticulata*) in double layers. Rogers doesn't recommend double-planting for hyacinths, which tend to push each other out of the soil. Your potted bulbs will require an initial cold treatment and proper subsequent care to force them into bloom.

Be Bold with Bonsai

"People don't realize how easy bonsai is," says John Lennon, the owner of J. Lennon Landscaping in California. "Everybody's afraid of them and they shouldn't be." Lennon feels that cultivating the exotic-looking dwarfed trees can be every bit as easy as growing any other trees in containers.

Lennon suggests starting with Japanese maples (*Acer japonicum* and *A. palmatum*) or junipers (*Juniperus* spp.), both of which are "forgiving." You can buy the starters sold in nurseries or simply start them from seedlings yourself. Japanese maples like to be kept moist, so be sure to water them frequently. They'll need a fair amount of sun, too. Junipers like more light (preferably full sun) but less water than maples do.

According to Lennon, one of the secrets of bonsai success is repotting the plant on a regular basis, as you would any containerized tree. It's best to perform this task during the plant's dormant stage, usually in winter. Every year or two, pull the bonsai tree out of its container, and knock off about one-third of the root ball with the three-pronged claw or other hand tool. (You can also use pruning shears to cut the excess roots.) "You've got to be brutal," says Lennon. "If you aren't vigorous with them, they won't come back vigorously." Repot the plant using fresh soil, then fertilize. The plant should eventually respond with plenty of new growth.

Pruning is, of course, central to bonsai care. "That's where practice comes in," says Lennon. He suggests taking off about one-third of the plant each time you repot it. Keep in mind that maples usually send out lots of new growth after they're pruned, so you'll need to prune the shoots regularly to keep the shape you have established. Junipers tend to produce most of their new growth all at once, so they won't need constant pruning.

According to Lennon, how you prune depends on the effect you want to achieve. For instance, if you want your maple to look as natural as possible, you'll need to round out the crown of the plant. Removing most of the branches from one side of a juniper can give it a kind of windswept look. Regardless of the style you choose, it's best to keep the center open to allow for good air circulation and prevent problems with pests.

Best for Hanging Baskets

For attractive undoor hanging baskets, try these plants recommended by Tovah Martin, the staff horticulturist at Logee's Greenhouses in Connecticut:

Aeschynanthus spp. (lipstick plants)

Begonia 'Tom Ment 1,' 'Orange Rubra,' and 'Elaine' (angel-wing begonia cultivars)

Columnea spp. (columneas)

Kalanchoe pumila, *K. uniflora* (kalanchoes)

Pelargonium peltatum (ivy geranium)

Container Plants the Low-Maintenance Way

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

Whether you're growing tubs of herbs and vegetables on the deck or houseplants in a sunny window, growing plants in containers adds a dimension to gardening that's hard to pass up. Growing plants in pots lets you move plants at will: You can easily bring a cherished tender herb like rosemary indoors to protect it from winter cold or grow an ever-changing display of flowers on a deck or patio. It also puts you in control of the growing conditions. You can garden if the soil is lousy, plant when you have the time, and use every available space. With containers, you can take advantage of light and moisture wherever you find them—in sunny stairwells and steamy bathrooms, under trees, or out front beside your driveway.

In this section, you'll find tips and techniques for making container gardening even more enjoyable than it already is.

Simple Steps to a Successful Container Garden

It doesn't take much to keep container plants happy. Since you control the soil, water, and light, it's easy to provide perfect growing conditions. For the best results and the least hassle, group plants with similar needs in a single container. If you mix sun-loving flowers with shade lovers, or mix plants that need lots of water with those that don't, you'll drive yourself crazy trying to keep all of them happy and healthy.

GROW GREAT PLANTS WITH THE RIGHT SOIL MIX

Choose a commercial container mix or make your own to get potted plants started right. A good mix drains well, retains moisture, and provides support for your container plant. Experiment with a few to find the one that's right for your plants. Or buy a mix and doctor it.

For a good do-it-yourself mix, combine 1 part potting soil and 2 parts organic matter—compost, shredded bark, leaf mold, or any material large enough to improve drainage and lend stability. Sharp sand, used by masons (available at most lumberyards), is another good option.

You can tailor it to fit your watering habits, too. If you like to water often, use sharp sand to increase drainage in your mix; if you grow on the dry side, add organic matter like compost to hold moisture between waterings.

LET THERE BE THE RIGHT AMOUNT OF LIGHT

You can make any container plant happy. Move pots to the shade if the sun gets too bright, or set them in the sun if that's what your plants prefer. Cluster sun lovers together in a hot spot so you can water them with a quick once-over. Let shade-tolerant combinations grace bare spots under trees and in dark corners.

ADD WATER AND LET THE PLANTS GROW

Once plants are potted and placed in an area with adequate light, all they need is water. Give them the right amount when they need it, and you'll have healthy plants and few maintenance chores.

Use the knuckle test to know when to water clay or plastic containers. Stick your finger into the soil down to the first knuckle. If your fingertip is dry, it's time to water. How much is enough? Irrigate every pot until water flows out the bottom. If your plant drains into a saucer, throw out the excess.

Because container-grown plants have restricted root space, they're often nutrient-stressed. To keep your container garden growing vigorously, plan on feeding regularly. Compost tea, liquid kelp, or fish emulsion are all fine fertilizers for container plants that you can apply when you water. As a rule, water at half the strength recommended on the container twice as often.

Container Options

The sky's the limit when it comes to choosing containers for your plants to grow in. Of course, there are hundreds of conventional containers to choose from. Explore as many as you can think of.

But don't just stop there. Container gardening means recycling. Plant in leftover pieces of pipe from plumbing projects, drain tiles that have been stood on end, rusty wheelbarrows, used tires, old bird cages—anything can become a planter/conversation piece in your garden. Where openings can't hold soil, make a liner of burlap or plastic screen.

Build a Space- and Labor-Saving Vegetable Box

Wooden fruit or vegetable crates from the grocery store—or their plastic equivalent, milk or storage crates—make great no-till vegetable garden boxes. If you grow in these handy

containers, you won't have to wait for soil to warm up or for the weather to improve; whenever you're ready to plant, the conditions are right.

Start your crate garden with burlap. Before filling your crates with your favorite soil mix and amendments, line them with burlap to keep soil from escaping. Then moisten the soil and start planting.

Just plant and grow. Small plastic milk crates are great for plants like lettuce and basil. For tall tomatoes or climbing cucumbers, use a wooden vegetable crate with a wire support. To make a simple support, after planting staple a 6-foot-tall section of hog wire (fencing with 4-inch squares) around the outside of the box. Attach it to itself for extra strength. Plants can lean or climb on the wire.

What Plants Need

When conditions aren't right, plants let you know—all you have to do is take a look at their leaves. A few commonsense cultural practices will cure most container plant problems.

Pale, stretched-out, spindly plants. Give these plants a brighter spot. If lower leaves turn yellow, water less often and feed with fish emulsion or another soluble fertilizer at a half-strength rate for two waterings to get them going again.

Plants that wilt even with adequate watering. Plants with this symptom may have root problems. Pull the plant out of its pot and take a look at the roots. If roots have filled all available space, divide the plant, repot it in new soil, and resume routine care. If roots are few or rotting, repot and let the soil dry between waterings.

Keep Herbs Close at Hand

When you're cooking, the last thing you have is time to waste. The sauce simmers, pasta's ready to serve, and you need some parsley. You don't have time to change shoes and tromp out to the garden. Turn instead to a convenient half-barrel filled with your favorite fresh herbs. A traditional strawberry pot works great, too; plant separate herbs in pockets on the jar's sides and they'll all have enough room to grow. Be sure to water from both the top and sides. When you need an herb, just snip off a sprig with scissors.

Take to Wheels for Easier Plant Care

Mobile gardening may not be an automotive trend, but putting containers on wheels lets you move them easily. Three-wheel steel dollies from your local hardware store make it easy to wheel huge pots about—whether you need to bring tender tropicals inside when seasons change or move large houseplants where you can water or spray safely away from carpets and furniture. Or bolt casters on a circle of plywood or other material. A wagon makes a great tool for rolling sun-loving annuals out to your shady patio to quickly decorate for a party. Or use it to move pot-grown tomatoes to safety when frost threatens.

Wick Away Indoor Water Cares

Containers with built-in reservoirs and wicks, and soil additives designed to conserve moisture, are modern technology's answer to tedious watering chores. Lots of "self-watering" pots work quite well. You can also make your own wick system.

Some plant care professionals use encapsulated moisture products to conserve water in container plantings. These water-absorbing polymers swell up to hold extra moisture and release it later. Other less expensive substances, like peat moss, vermiculite, and perlite, do the job as well or better in home environments.

Insert wicks when you pot. Cotton wicks, pieces of wool or cotton yarn, and strips of panty hose all make fine wicks. Insert them halfway up the container, through the drainage hole, when you pot.

Buy wick waterers. Many companies offer pots with built-in wick-watering systems. These have a reservoir, a tube to fill it, a wick that runs up into the medium, and often a water-level indicator.

Watering made easy. To water, just fill the reservoir. Until you're sure your wick system is working properly, also check the soil regularly to make sure it's damp enough.

Use Household Items to Keep Plants from Drowning

A saucerful of water can mean root rot or death for plants like rosemary that demand well-drained soil. Try these tips for getting rid of that water without breaking your back.

Best Bets for Least-Work Potted Plants

Successful container gardens start with plants that like container life. Use these tips to find the best plants for your potted garden.

Look for drought-tolerant plants. Drought-tolerant herbs, ornamental grasses, annuals such as geraniums and marigolds, and many perennials, including daylilies, sedums, and hardy cacti (*Opuntia* spp.), make fine container residents. Fleshy leaves are a good clue to go by when you're looking for drought-tolerant plants: Plants that have them, like sedums, can hold on to water better than plants with thin, papery leaves.

Continued ➔

Select dwarf shrubs and trees. You'll find a wide variety of dwarf shrubs and trees to choose from at well-stocked nurseries and garden centers. Dwarf cultivars generally have smaller root systems, grow slowly, and keep pleasing proportions for years. Those qualities translate into less work for you since they'll rarely need pruning or repotting.

Grow fruits, vegetables, and herbs. You can grow dwarf fruit trees, herbs, and a wide variety of vegetables (compact cultivars are best) on a sunny site in a variety of tubs and pots. Lettuce and other salad greens will perform well in a half-day of sun.

Try tropicals. Shallow-rooted tropical foliage plants seem to defy gravity. The huge leaves that emerge from small root systems make them ideal for growing in pots.

Plant groundcovers. Groundcovers provide living mulch beneath potted trees, suppress weeds, and often deliver bonus blooms. Try annual groundcovers like sweet alyssum, evergreen ones like creeping junipers, or flowering perennials like creeping thymes, sedums, or hen-and-chicks.

Grow flowers to keep your garden colorful. Perennials and annuals keep container plantings blooming nonstop until frost. If you're growing a potted tree that blooms in spring, put summer and fall-flowering perennials in the same container to extend the bloom. Or grow several smaller pots of perennials and bring them front and center while they're flowering. Annuals have shallow root systems that make them terrific companions to any container plant. Try sweet alyssum, coleus, impatiens, petunias, or marigolds, just for starters.

Plant sprawlers to dress up containers. Quick color and instant cover change even worn or stained containers into flower-filled beauties. Any plants that cascade or sprawl, like petunias, vinca, creeping thyme, and trailing junipers make good choices since their foliage drapes and decorates any pot. And don't forget annual vines like black-eyed Susan vine (*Thunbergia alata*). Plant a pot of each, or mix and match.

Make friends with invasive plants. Put unmanageable mints and intrusive bamboos in half-barrels on a patio or in plastic pots or bottomless buckets set in the ground. Sink pots of bog plants into the sides of water gardens; they'll get needed moisture without troubling fish and filter systems.

Grow Patio Pots for Year-Round Interest

It doesn't take lots of space, plants, or bother to decorate your deck, patio, or porch with nonstop color. Fill a large, sturdy container with a variety of plants chosen for their hardy habits, successive seasonal color, contrasting textures, and eye-pleasing forms. It can stay outside all year to brighten your landscape in every season.

Select a small tree or shrub with attractive winter twigs, evergreen foliage, or colorful berries, add bulbs to bloom in spring, a perennial plant to flower during the summer, and an evergreen groundcover to complement the planting and keep weeds away.

Indoor Herbs Aplenty

Roger Yepsen

A pot of carefully pruned rosemary or spicy bush basil makes an attractive windowsill plant, but you'll probably be reluctant to snip off much for cooking. And chances are that if you love plants, your south-facing windows are already filled to capacity. So, if you really like to cook with fresh herbs year-round, consider arranging a light table for them. This involves setting up fluorescent shop lights over a sturdy table or shelf that won't be marred by water. It's almost like having an attached greenhouse—on a far more modest scale, of course.

For most plants, provide at least 12 hours of light a day from a two-tube fixture suspended about 6 inches above the plants. You can hang the lights from two or three sturdy brackets. Place the brackets over studs in the wall above the windows and drive screws to anchor them securely. To locate the studs, you can use a magnetic or electronic stud finder. Or, look at the baseboard or chair rail trim and note where it has been nailed; if these locations are 16 inches on center, they indicate the studs' positions within the wall.

Give Indoor Herbs a Boost

If you bring your favorite herbs indoors for the winter rather than sacrificing them to the frosts of fall, they may not reward your kindness with lush growth. They are apt to go dormant, performing sluggishly. Here's a way to goose them into growing with youthful energy.

1. Pot up the plant and boldly cut back the top growth to just 2 or 3 inches.
2. Place the plant in a clear plastic bag with the opening on top and seal it.
3. Create a false winter by placing the potted plant in the refrigerator for 2 weeks, subjecting it to another 2 weeks in the freezer, and then moving it back to the refrigerator for a final 2 weeks.
4. Place the plant on a sunny windowsill with the bag open and look for new growth.

Ultra-Light Potting Mix

Joan Benjamin and Deborah L. Martin

You can still move even really big containers if you fill them with this ultra-light mix developed by New Yorker Linda Yang, author of *The City and Town Gardener*. The mix's lightness comes from the large proportion of perlite, a porous, very lightweight soil amendment.

Ingredients and Supplies

5 parts perlite

1 part soil

5 parts peat or compost

Organic fertilizer or dehydrated cow manure

Directions

1. Moisten the perlite to reduce the dust, then mix all the ingredients together.
2. Add a handful of granular organic fertilizer or a trowelful of dehydrated cow manure to each 3 gallons of mix.
3. Use this light mix to fill hanging baskets, windowboxes, and balcony or rooftop garden containers. Keep an eye on moisture—this mix drains quickly.

If you're planting shallow-rooted annuals in a large, deep container, reduce the weight by filling the bottom part of the container with empty plastic bottles of Styrofoam "peanuts." A layer of burlap will save you from picking lightweight fillers out of your potting mix when it's time to repot.

Super-Simple Potting Mix

What could possibly be simpler than this two-ingredient container mix recipe from Connie Beck, who teaches vocational horticulture in San Diego County, California. You can buy perlite—a very lightweight natural mineral—at garden centers.

Ingredients and Supplies

1 part perlite

1 part compost (sifted)

Directions

1. Moisten the perlite before you start mixing—it's usually very dusty.
2. Mix the perlite into the compost, and you're ready to plant!

Note: Connie says that this mix is so good at preventing diseases that she lacks examples of plant problems to show her students.

Overhead Herbs

Roger Yepsen

It may be ornamental rather than strictly practical, but a kitchen seems to look more like a no-nonsense workplace if there are bundles of herbs hanging to dry from joists. Or, if you don't have an old farmhouse with authentic exposed joists, simple hooks on a wall will do. Cut the stems just above ground level to facilitate tying bundles with twine. The less-humid air of fall may help the herbs to dry. But unless your house is unusual, kitchen oils and dust will conspire to coat these herbs with an unappetizing fur. So either use them fairly promptly or treat them as nonfunctional decoration, something like wax fruit in a glass bowl.

Plant a Potted Kitchen Herb Garden

Barbara Pleasant

Think you don't have room for a kitchen garden? Think again! Planting culinary herbs in pots lets you dress up your deck, porch, or patio with plants that are pretty as well as productive. Plus, it's easy to move them around or replace plants that are past their prime, so they'll always look their best.

Herbs can grow equally well in individual pots or grouped into larger planters. Even for gardeners who have plenty of garden space, single pots are ideal for herbs that spread rampantly by creeping roots or stems, such as mints. Containers also make it easy to bring herbs indoors in fall and extend your harvest into winter. On the downside, individual pots have limited space for roots, so they tend to need frequent watering and fertilizing. Larger planters provide more rooting room, but they also tend to be heavy and difficult to move. Consider using a mix of container sizes to enjoy the advantages of each.

There's no one best type of container for kitchen herbs—anything that can hold potting soil will do the job, as long as it has holes in the bottom for drainage. If your potted garden is in a highly visible spot, set the herbs directly into decorative planters, or grow the herbs in plastic nursery pots and slip them into prettier planters. Fill your chosen containers with an all-purpose potting soil, but not regular garden soil, which can compact tightly with regular watering.

During the growing season, water regularly to keep the soil evenly moist; small pots may need to be watered as often as once a day during dry, windy weather. Also, fertilize once every 2 to 3 weeks with diluted fish emulsion or a commercial organic liquid fertilizer to keep the plants healthy and vigorous. Herbs

Continued →

normally aren't bothered much by pests or diseases, but if you notice any problems, pinching off the affected parts is an easy way to stop them from spreading.

The possible combinations of plants and pots is limited only by your imagination, but to get you started, here's a simple plan for a basic container herb garden comprised of three containers. Once you get the hang of growing herbs, personalize the planting plan for your particular needs!

You Will Need

Tools: Watering can, hand trowel

1 round container, 14 inches in diameter

1 rectangular window box container

1 hanging basket container

One 40-pound bag of potting soil (more for larger containers)

Container-grown herb plants

For the large round planter:

1 clump of chives

1 fennel plant

1 sage plant

1 French tarragon plant

For the window box:

1 basil plant

2 parsley plants

1 spearmint plant

For the hanging basket:

1 Greek oregano plant

1 creeping rosemary plant

1 English thyme plant

1. Thoroughly water the purchased herbs, and trim away any yellowed leaves or damaged stems.
2. Fill all three containers to within 2 inches of the top with purchased potting soil. Push the herbs from their pots by squeezing on the bottoms and jiggling the plants free. Set the plants in place, beginning with the largest plant in each group.
3. Add potting soil to fill in spaces between the herbs. Tap or gently shake the containers to help settle the soil in place. Add additional soil until the tops of the root balls are barely covered.
4. Set the containers in place, and water thoroughly with room temperature water. Wait several hours or overnight, and water the containers again.

Welcoming Wildlife

WELCOMING WILDLIFE

Wildlife and Birds

Jeff Cox

While you're planning and dreaming about your yard and garden, don't overlook the joys of attracting wildlife and birds. Your yard can become a veritable Noah's ark if you provide the basics for nature's creatures: food, water, shelter, and a safe place in which to reproduce and raise the next generation. With careful planning, you can develop even a tiny yard to attract a surprising array of wildlife and birds. Small occupants, such as rabbits, squirrels, and birds, can become near-permanent breeding residents. Animals with larger territories, such as deer and foxes, may appear for a visit as their travels come to include your backyard as a regular stop.

Attracting Wildlife

Although wild birds have been welcome backyard and garden visitors for decades, other forms of wildlife have generally been greeted with much less warmth. But growing numbers of gardeners across the country are developing a new attitude toward squirrels, rabbits, mice, toads, salamanders, crickets, and all the rest that the neighborhood ark might hold.

Look at your backyard from a new perspective—one of wildlife in search of food, water, cover, and a safe place for their young. When viewed in this light, tangled brush, tall weeds, and dead trees take on a much more essential role than manicured lawns and rows of flowers.

Food To make your sanctuary attractive to a number of species, you'll need to include a variety of plants. The cottontail rabbit, for example, eats herbaceous plants such as grasses and clovers for much of the year and in winter adds the twigs and bark of young trees and shrubs. The eastern gray squirrel is most decidedly a nut eater—primarily acorns, hickory nuts, and

More on Wildlife

In 1991, the National Wildlife Federation registered its ten-thousandth backyard habitat. That number represents only those gardeners who took the time and trouble to officially register the wildlife-friendly habitats they had developed. Millions of others—the Federation estimates more than 12 million—are enjoying the fruits of attracting wildlife into their backyards without any official recognition whatsoever. For information on registering your backyard, write to Backyard Wildlife Habitat Program, National Wildlife Federation, 1400 16th Street NW, Washington, DC 20036-2266.

beechnuts—but corn is also a great attraction. Birds depend on insects as their mainstay, adding seeds, berries, and fruits.

Raccoons relish crayfish, grasshoppers, frogs, and birds' eggs, but almost any living creature that is smaller and slower than a 'coon will find its way into its diet. Acorns, corn, and fleshy fruits also are favorite raccoon foods. Most of the diet of the red fox is small rodents, such as mice, voles, and rabbits. In summer and fall, fox diets also include as much as 25 percent fleshy fruits. The browsing diet of the white-tailed deer consists largely of twigs from trees and shrubs but is supplemented in spring and summer by many of the same herbaceous plants cottontail rabbits eat.

Shelter Tall and mid-sized trees, shrubs, tall herbaceous plants, grasses, and groundcovers all provide for varying needs of different species. Weeds and wildflowers also play their part where local ordinances and neighbors will allow.

Consider seasonal diversity, too. Different plants produce their buds, fruits, and seeds at different times of the year. Some plants, such as evergreens, supply shelter year-round. The brambly interior of a blackberry patch makes a good escape route for small animals such as rabbits, even in winter.

You'll attract the most wildlife by mimicking the plantings of nature. Wild animals stay safe from predators by moving from place to place through protective cover. An isolated berry bush may attract a migrating group of cedar waxwings, but a grouse who tries to reach it could soon become hawk food. If you add another few bushes, and perhaps a hemlock (*Tsuga* spp.), and front the shrubs with meadow grasses and wildflowers, you'll make the planting attractive to a variety of wild creatures.

To this living landscape add snags, logs, brush piles, and rock piles to provide places for smaller creatures to hide and to rear their young. You can camouflage these elements by planting vines like wild grapes or Virginia creeper (*Parthenocissus quinquefolia*) to trail over them. In the process, you'll provide additional food sources.

Water Water is the most overlooked aspect of backyard wildlife habitats. Food and cover preferences vary widely, but nearly all creatures need water. A birdbath will serve many birds, many insects, and some mammals. A ground-level fountain will provide for even more drinkers and might also attract some amphibians. A small pond of varying depth will find use by nearly every creature that you can expect to draw into the backyard and can even provide a permanent home for frogs and turtles.

Attracting Birds

Birds are most gardeners' favorite visitors, with their cheerful songs, sprightly manners, and colorful plumage. Birds are also among nature's most efficient insect predators, making them valuable garden allies. In an afternoon, one diminutive house wren can snatch up more than 500 insect eggs, beetles, and grubs. Given a nest of tent caterpillars, a Baltimore oriole will wolf down as many as 17 of the pests per minute. More than 60 percent of the chickadee's winter diet is aphid eggs. And the swallow lives up to its name by consuming massive quantities of flying insects—by one count, more than 1,000 leafhoppers in 12 hours.

Unless your property is completely bare, at least some birds will visit with no special encouragement from you. Far more birds, however, will come to your yard and garden if you take steps to provide their four basic requirements: food, water, cover, and a safe place in which to raise a family. Robins, nuthatches, hummingbirds, titmice, bluebirds, mockingbirds, cardinals, and various sparrows are among the most common garden visitors.

LANDSCAPING FOR BIRDS

Feeders, birdbaths, and birdhouses play important roles in attracting birds. But trees, shrubs, and other vegetation can do the whole job naturally. Plants provide food, cover, and nest sites, and because they trap dew and rain and control runoff, they help provide water, too.

When adding plants to your landscape, choose as many food-bearing species as possible, with enough variety to assure birds a steady diet of fruit, buds, and seeds throughout the year. Mix plantings of deciduous and evergreen species in order to maintain leafy cover in all seasons. Species that are native to your region are generally best because the local birds evolved with them and will turn to them first for food and cover. Combine as many types of vegetation as possible: tall trees, shorter trees, shrubs, grasses, flowers, and groundcovers. The greater the plant diversity, the greater the variety of birds you will attract to your yard.

Hummingbirds have their own landscape favorites. Preferred trees and shrubs include tulip tree (*Liriodendron*

tulipifera), mimosa (*Albizia julibrissin*), cotoneasters (*Cotoneaster* spp.), orange-eye butterfly bush (*Buddleia davidii*), flowering quinces (*Chaenomeles* spp.), and rose-of-Sharon (*Hibiscus syriacus*). Favored perennials include columbines (*Aquilegia* spp.), common foxglove (*Digitalis purpurea*), alumroots (*Heuchera* spp.), cardinal flower (*Lobelia cardinalis*), penstemons (*Penstemon* spp.), torch lilies (*Kniphofia* spp.), sages (*Salvia* spp.), and delphiniums (*Delphinium* spp.).

Of course, there is the flip side to landscaping for the birds, especially if you grow berries for your family. Bird netting may be a necessity if you don't want to share your cherries and blueberries with your feathered friends.

PROVIDING FEEDERS

Food is the easiest of the four basic requirements to supply. Even if you live in a city apartment, you can attract birds by putting a feeder filled with seed on your balcony. If your landscape is mostly lawn and hard surfaces, you can use feeders as the main food supply while you add plantings of fruiting trees and shrubs. And if your yard is a good nature habitat, where plants are the primary food source (as they should be), feeders can provide crucial nourishment during winter, drought, and other times when the natural food supply is low. Besides, carefully placed feeders allow you and your family to watch and photograph birds.

Some birds, including juncos, mourning doves, and towhees, feed on the ground, while others, including finches, grosbeaks, nuthatches, titmice, and chickadees, eat their meals higher up. In order to attract as many different birds as possible, use a variety of feeders—seed tubes, broad platforms, and shelf and hanging types. Place them at varying heights, widely separated from one another, and near the protective cover of a tree or shrub if possible. No matter what the style, the feeder should resist rain and snow, should be easy to fill and clean, and should hold enough birdseed so that you don't have to refill it every day, but not so much that the food spoils before it can all be eaten.

WATER ALL YEAR

Under normal conditions, most birds get all the water they need from the food they eat, from dew, and from rain. Nonetheless, a reliable water source makes life easier for birds—and can be critical during drought or in arid regions.

A birdbath or shallow pan set in the open and at least 3 feet off the ground, with shrubs or overhanging branches nearby to provide an escape route from cats or other predators, is ideal. The water in the bath should be no deeper than 3 inches. Birds are particularly attracted to the sound of moving water, so it helps to hang a dripping hose (or a leaky can or jug, filled with water daily) from a branch over the bath.

Birds need water in winter, too. Commercial immersion water heaters will keep the water in birdbaths thawed in winter. They are available from stores and mail-order supply houses that sell bird supplies. You can try to keep water from freezing by pouring warm water into the baths as needed, but on very cold days this requires a lot of pouring.

COVER AND NEST SITES

Cover is any form of shelter from enemies and the elements. Different bird species favor different kinds of cover. Mourning doves, for example, prefer evergreen groves; others prefer the refuge of densely twiggy shrubs. Likewise, most species require a particular kind of cover in which to raise a family. Some birds, including red-winged blackbirds, nest in high grass; others, such as cardinals, nest in dense foliage; and still others, such as woodpeckers, need wooded land.

You can add more nest sites and attract many types of birds to your yard with birdhouses. Different species have different housing requirements, but there are ready-made birdhouses and build-your-own plans for everything from bluebirds to barn owls. Whichever birdhouse you choose, make sure that it is weather-resistant, that its roof is pitched to shed rain, and that there are holes in the bottom for drainage and in the walls or back for ventilation. A hinged or removable top or front makes cleaning easier. Position birdhouses with their entrance holes facing away from prevailing winds, and clean out the nesting materials from the boxes after every nesting season.

Why Welcome Wildlife?

Barbara Pleasant

From the buzz of insects to the trill of bird songs, wild creatures of all shapes and sizes help connect us to the natural world. Their natural rhythms—migrating, hibernating, raising young—help free us from the unnatural rhythms our own lives sometimes follow. Their beauty rests our eyes, while the intricate behaviors of wild things are as amazing as the most complex technology. And the very presence of wildlife tells us about the health of our environment. An abundance of wild creatures, from microscopic to massive, is a sign that our surroundings are as healthy for our families as they are for theirs.

Welcoming Wildlife Back

Wherever you live, there's little doubt that it once was home to a much greater number and variety of wild animals than it is today. By adapting our landscapes to make them more inviting to wildlife, we are welcoming nature back to its old haunts. Before you set out feeders and houses, sow butterfly-magnet plants, or install a natural pond, take a look at your current gardening practices. Some things may need to change before your yard is ready to host buntings and bunnies.

Continued →

KEEP YOUR LANDSCAPE PESTICIDE-FREE.
Most songbirds eat insects at some stage in their lives, so spraying poisons on bugs is like feeding it to the beautiful birds you hope to attract. And, because butterflies *are* insects, it makes little sense to spray pesticides if you enjoy seeing butterflies flutter through your yard.

CURB YOUR PETS.
Even well-fed house cats love to hunt, so if you're luring birds to your yard with food, make sure you're not luring them to their deaths. Keep Kitty indoors, or make her wear a bell that warns wildlife when she is near, and ask your neighbors to do the same with their cats. Dogs also hunt instinctively and will harass any critters that catch their attention. If you're serious about making wild animals feel at home at your place, set some boundaries with your pets.

GIVE UP YOUR MANICURE.
A bare expanse of closely cropped grass punctuated with a small tree and tightly pruned shrubs is about as uninviting to wildlife as an acre of asphalt. Wildlife thrives along landscape edges, where grasses and flowers give way to the shelter of shrubs and trees. Be as orderly as you like close to your house, but enhance your yard's edges to make it more hospitable to wildlife.

Wildlife-Friendly Landscaping

As you lure in wildlife, don't worry that your yard will turn into a wild jungle—and you certainly don't have to sacrifice your vegetable garden. Instead, take a positive approach by stocking your yard with wildlife-friendly plants, arranged in ways that are pleasing to you and to your wild visitors.

- Look for ways to create pathways for wildlife to travel through your landscape.
- Plant a hedge that includes berry-producing shrubs and evergreens for year-round shelter and winter food.
- Work with your neighbors to form connected greenways for birds and animals.

Balancing Benefits

It's natural that the pleasure you find in gardening should lead you to an interest in your landscape's wild side. Yet when it comes to wildlife, cute is in the eye of the beholder. Chipmunks are fun to watch until they uproot an entire planter full of pansies while digging for seeds. Deer appear elegant until they eat a patch of expensive tulips you've waited all winter to see bloom.

Gardening to attract wildlife is a balancing act between your commitment to preserve and protect nature and your desire to create a landscape that satisfies your family's needs for food, recreation, and beauty. You can achieve both goals by taking a strategic approach to sharing your landscape with wildlife.

Trees and Shrubs for Birds

To attract birds to your landscape, look at plants from a bird's point of view. Do they provide food and shelter? Nest sites? Try to plant a variety to provide birds with protective cover and a varied diet throughout the year. The following trees and shrubs are excellent food sources—producing berries, nuts, or seeds that birds will flock to. Evergreen species provide food but are also especially important for winter cover. These species will grow in most regions of the country.

Evergreen Shrubs

- Chinese holly (*Ilex cornuta*)
- Cotoneasters (*Cotoneaster* spp.)
- Japanese yew (*Taxus cuspidata*)
- Oregon grape (*Mahonia aquifolium*)

Deciduous Shrubs

- American elder (*Sambucus canadensis*)
- Bayberries (*Myrica* spp.)
- Blueberries (*Vaccinium* spp.)
- Common buckthorn (*Rhamnus cathartica*)
- Japanese barberry (*Berberis thunbergii*)
- Pyracanthas (*Pyracantha* spp.)
- Raspberries and blackberries (*Rubus* spp.)
- Red-osier dogwood (*Cornus sericea*)
- Sand cherries (*Prunus pumila, P. besseyi*)
- Viburnums (*Viburnum* spp.)

Evergreen Trees

- American holly (*Ilex opaca*)
- Canada hemlock (*Tsuga canadensis*)
- Douglas fir (*Pseudotsuga menziesii*)
- Eastern red cedar (*Juniperus virginiana*)
- Pines (*Pinus* spp.)
- Spruces (*Picea* spp.)

Deciduous Trees

- American beech (*Fagus grandifolia*)
- Cherries (*Prunus* spp.)
- Common persimmon (*Diospyros virginiana*)
- Crab apples (*Malus* spp.)
- Flowering dogwood (*Cornus florida*)
- Hackberries (*Celtis* spp.)
- Hawthorns (*Crataegus* spp.)
- Hickories (*Carya* spp.)
- Oaks (*Quercus* spp.)
- Serviceberries (*Amelanchier* spp.)
- White ash (*Fraxinus americana*)

Successful Sharing

The old saying about good fences making good neighbors is practical guidance when it comes to sharing your landscape with wildlife. As much as human development allows, wildlife live, roam, and eat according to their instincts. Most of the wild creatures that enter your domain will show little interest in your gardens, but it takes only one or two troublemakers to take the pleasure out of playing host to your wild neighbors. A little planning—and some sturdy fencing—can help keep wildlife from raiding your garden and spoiling your fun.

- Place feeding stations away from your vegetable garden, fruit trees, and berry patch.
- Provide desirable alternatives. Plant a mulberry tree to give fruit-eating birds something other than your blueberries and cherries to dine on; sow a patch of "bunny" lettuce far from your garden and close to sheltering shrubbery.
- Use fences, netting, rowcovers, passive scare devices, and other techniques to keep your food from becoming their food.

Give 'Em Shelter

Providing shelter is the best way to attract different kinds of wild creatures to your landscape. Every creature needs a place to hide from predators, rest, and perhaps raise their young. More than shortages of natural food or water, a scant supply of suitable habitat is responsible for the shrinking populations of many wild species. Giving wildlife a place to live and reproduce in your landscape can be a treat for you, too. You'll have the chance to see species that don't visit feeders, and you may enjoy the rare pleasure of watching fledgling birds testing their wings in first flight, or the remarkable sight of a mother opossum with her babies clinging to her back.

HEDGE YOUR BETS

Creating shelter for wildlife is relatively simple. While you might think first about building houses for birds and animals, most wild animals—even the cavity-nesters that houses are meant for—prefer natural sites for nesting and cover. With a little planning, your landscape can include the sorts of natural shelter that wild birds and animals like best and need most. A well-placed evergreen windbreak, for example, can help lower your heating costs by sheltering your house from winter winds, and at the same time provide roosting and nesting places for birds, as well as cover for many small mammals.

Like an evergreen windbreak, a hedge of mixed evergreen or deciduous shrubs creates superb shelter for wildlife. By providing a long row of unbroken shelter, a hedge lets small animals move through their habitat unseen by predators. It offers safe nesting spots for songbirds, and a place where they can dash for cover when a hawk flies overhead. Hedges that include fruit-producing plants serve as a food supply, too.

Who's at Home in Your 'Hood?

Where you live determines, in large part, what species of wildlife are likely to appear in your yard. A visiting armadillo is an improbable (at best) guest in a Minnesota garden, and a Steller's jay (a western species) would be a surprising rarity in South Carolina. Visit your local library, talk to wildlife-minded neighbors, or join a bird-watching group to learn more about what kinds of birds, reptiles, and mammals call your region home. Then take steps to provide the types of food and shelter that will make them feel welcome in your landscape.

A wildlife hedge need not be carefully pruned, and will probably be more attractive to you, and to wildlife, if it is comprised of a tangle of evergreen and berry-bearing deciduous shrubs. The plants listed below are easy to grow and can be woven into a wildlife-friendly hedge. If you don't have room for a long hedge, try mixing shelter and food shrubs together by grouping several along the outer edge of your landscape.

12 TERRIFIC SHELTER AND FOOD SHRUBS

Barberries (*Berberis* spp.)
Bayberries, wax myrtles (*Myrica* spp.)
Cranberry bush (*Viburnum trilobum*)
Elderberries (*Sambucus* spp.)
Hollies (*Ilex* spp.)
Junipers (*Juniperus* spp.)
Lilacs (*Syringa* spp.)
Mahonia (*Mahonia aquifolium*)
Manzanitas (*Arctostaphylos* spp.)
Ninebark (*Physocarpus* spp.)
Rugosa rose (*Rosa rugosa*)
Yews (*Taxus* spp.)

STAND UP FOR SNAGS

A dead, decaying tree, which is called a snag, may not fit your vision of landscape loveliness, but it's an ideal home for many cavity-nesting birds and animals. The most adorable birdhouse you can imagine won't get a second look from chickadees, nuthatches, titmice, woodpeckers, and wrens if there's snag space available. Kestrels and owls often move into holes created by woodpeckers, as do squirrels and raccoons. In addition to spaces for nesting and roosting, snags often host wood-eating insects, so they are also a food source for insect-eating birds and mammals.

Continued →

Whenever possible, leave room in your landscape for this perfect wildlife refuge. If you find yourself confronted by a landscape tree that is dead or dying, consider your options before firing up the chain saw.

- Is it a hazard to people or property? Sometimes trimming off a few limbs reduces the likelihood that the tree might cause damage.
- Can you leave a significant part of it? A 12- to 20-foot trunk is better than no snag at all.
- Is it attractive? With the addition of plants, feeders, or drilled nesting holes, a dead tree may become the liveliest focal point in a wildlife lover's landscape.

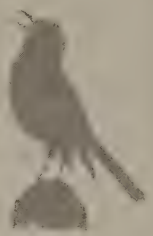
If the top of the remaining trunk is at a reasonably accessible height (for you, not for the birds), top it with a birdbath or a hopper feeder. Drill holes into the trunk and stuff them with suet or peanut butter. Drive a few long nails into the trunk and use them to serve halves of apples or oranges. Mount a hanger arm and hang a tube feeder from it. Birds will flock in to enjoy the treats you provide.

Don't worry, by the way, about the insects that arrive to chomp and chew through the decaying wood of a dead tree—they're not about to attack other plants in your landscape. The insects that feast on dead trees are specifically there for that purpose, and healthy landscape plants are not their cup of tea.

However, insect-eating birds regard wood-chomping insects as a delicacy. Snags often attract woodpeckers and other birds for whom wood-eating insects are dietary staples.

Lay Down the Log

If a standing snag isn't feasible in your landscape, consider a log instead. You can turn a section of a fallen tree trunk or even a substantial branch into a "horizontal snag" by simply placing it on the ground. Once it's in place, wildlife will discover the log and move in. Small mammals like chipmunks and rabbits will nest under it, as will toads, snakes, salamanders, and lizards. Woodpeckers will fly in to hunt for insects during the day, and skunks may make nighttime visits for the same reason. To find a suitable piece of dead-wood, ask permission to search in local woods, particularly after a storm has moved through the area. Utility companies, tree services, and parks departments are other potential sources for a nice log.



Your Backyard as a Wildlife Habitat

Sally Roth

When I decided to turn my front yard into a wildlife haven, I started with a budget of $100—not much in landscaping dollars. I knew it wouldn't stretch to let me do the whole front yard, so I started small, focusing on a grouping of berried shrubs. I planted three deciduous winterberry hollies in a single group, curving them around a flat-topped rock that held a clay saucer—an impromptu bird and chipmunk watering hole that served for years until I got around to putting in the stone recirculating basin on my master plan.

That was almost a garden all by itself, but I added wildflowers and spring bulbs around their feet for spring interest, then mulched with lawn mower–chopped oak leaves. I was pleased with the first step, and so were the birds. Bluebirds and thrushes arrived within weeks, feasting on the berries and splashing in the bath. When the berries were gone, the protective branches of the shrubs gave the birds at my nearby feeders a new place to perch.

The following spring, when my wallet was a little fatter, I added on to my original planting. I created a second planting near the first, but based it on blueberries and viburnums. By extending the planting of wild blue phlox (*Phlox divaricata*) and other wildflowers from one group of shrubs to the next, the two pieces merged into a single garden.

Gardening bit by bit lets me extend my garden whenever the time is right. Each new piece is a satisfying garden in itself, and the whole thing expands gradually. Best of all, it looks good right from the start. I keep it from looking schizophrenic by repeating colors and plants throughout. Spicebushes, for example, are a repeating theme that helps tie things together.

Bringing in the Good Guys

Sally Jean Cunningham

When you use my companion-gardening system, you group your crop families and their plant friends together in garden neighborhoods. That means they'll live and grow together in peace and harmony, right? Not always! Now the outsiders start to arrive—insects and animals, invited or not. They come flying, crawling, digging, and marching right into your happy plant community. But most of them will be welcome guests, those wonderful beneficial insects that you've attracted by planting flowers and herbs. They're your main line of defense against the pest insects that will also inevitably drop in. In this section, you'll learn all about the "good guy" insects: how they control pests, what they look like, where you'll find them in your garden, and more special techniques you can use to help them thrive.

Taking a Bug's Eye View

Insects fascinate me. When I first studied organic gardening, I was delighted to discover that most of the insects in my garden are my allies in fighting pests. But many people find it hard to believe that most insects are beneficial, because long ago somebody taught them to be afraid of insects and say "Eeeuuuw" when they saw a spider or an ant. Most of those in the insect-fearing crowd will concede that a few insects do good things—but don't let those "bugs" get too close!

Those folks would be surprised to learn about the major roles insects play in the survival of our planet. For example, without insect pollination, there would be food shortages, because about one-third of the food we eat comes from plants pollinated by insects. Insects are critical to the decay cycle that returns nutrients to the soil. They're also an important part of the food chain for birds, fish, frogs, and other animals.

INTRODUCING THE GOOD GUYS

So who are all the "good guys"? Lady beetles probably top most people's lists, followed by praying mantids and honeybees. Of course, spiders are helpful, and so are pest-eating lightning bugs, and then there are earthworms—certainly worth their weight in gold, even if they're not insects. But they're just the beginning. Believe it or not, 95 to 99 percent of all insects are beneficial or harmless to human life and endeavors.

There are four main job descriptions for beneficial insects: predator, parasitoid, pollinator, and soil builder/garbage collector. Whether you see them at work or not, you can bet your companion garden employs thousands of beneficial insects carrying out these four important jobs.

Like all insects, beneficials have distinct stages in their life cycles. Some types of insects undergo a process called complete metamorphosis. These insects emerge from eggs as larvae, such as caterpillars, which look completely unlike the adults. A larva feeds and grows, then forms a pupa (a resting stage in which the insect covers itself with a hard shell). After resting awhile in the pupa, the adult emerges.

Other types of insects have a lifestyle known as incomplete metamorphosis. These insects emerge from eggs as nymphs, resembling tiny adults. The nymphs feed and molt several times before reaching adult size and form. All stages in the life cycle of a beneficial insect can be helpful to gardeners.

INSECT PREDATORS

The most familiar beneficial insects—lady beetles and praying mantids—are predators. They hunt down and eat their prey just as the lion hunts the antelope. Predatory insects are usually larger than their prey, and often they hunt in the larval (caterpillar or grub) stage as well as in the adult stage.

Predatory insects usually prey on several kinds of insects. The praying mantis, for example, captures and eats just about anything it can wrestle to the ground—including another praying mantis! Many predators have names that are clues to their behavior: assassin bugs, ambush bugs, soldier beetles, and tiger beetles. Other colorful names describe the insect's appearance, like big-eyed bugs, dragonflies, and lacewings. Delicate lacewings can actually be fierce hunters. Certainly the larvae are voracious eaters—that's why they're nicknamed aphid wolves!

Paper wasps are also fine insect hunters. People are often afraid of these wasps, but they are rarely aggressive toward humans unless their lives are threatened. What paper wasps seek are full-size caterpillars, such as gypsy moth larvae and imported cabbageworms which the wasps feed to their young.

INSECT PARASITOIDS

Parasites are organisms that live their entire lives directly on the bodies of their *hosts*. Mistletoe is a well-known plant parasite that develops special rootlike structures that puncture tree bark and absorb water and nutrients from the trees. Fleas and lice are insect parasites.

Parasitoids, a special kind of parasite, live on the body of their hosts for only a part of their lives. Parasitoid insects lay eggs on or inside the body of a host insect, larva, or egg.

When the parasitoid larvae hatch, they feed on the host. The most common parasitoids are wasps and tachinid flies. Braconid wasps lay eggs in the bodies of tomato hornworms, and the larvae feed on the caterpillar. If you grow tomatoes in your companion garden, you will probably see tomato hornworms with little white bumps or growths attached, which are the wasp's pupae. The pupae develop when the hornworm is near death. More adult wasps will emerge from the pupae, ready to hunt down still more tomato hornworms.

Blooming with Ideas

There's no need to consult a professional designer to learn about good combinations—unlimited possibilities are right in front of your nose. Think about the spring wildflowers, a summer meadow, or the last hurrah before frost. How can you improve on wild blue phlox and Dutchman's breeches with a few trilliums thrown in for good measure? What could be more beautiful than madder-purple fall asters and a sweep of goldenrod, decorated with filmy plumes of virgin's bower vine? If you want a beautiful combination, borrow from nature.

I've learned to jot down companion possibilities when I see them. No matter how often I think, "Oh, I'll remember that," I never do unless I write it down. I'm not organized enough to keep a nice neat notebook, but even a scrap of paper in the pocket of my jeans serves the purpose.

A Backyard Wildlife Habitat

Think like a bird or a rabbit and you'll have a ready idea of what's needed to make a landscape appealing to wildlife—protective cover, food, and water. Supply these basics, and your backyard will soon be a fascinating place alive with birds, bugs, and animals.

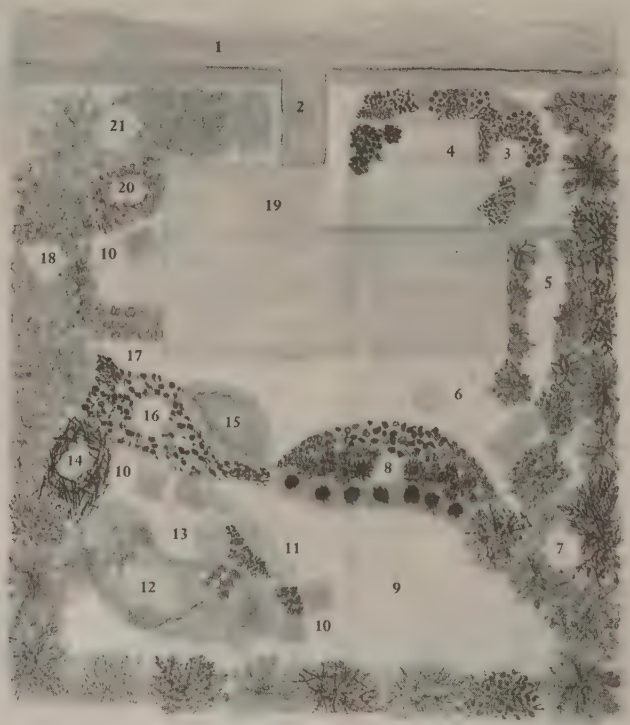
You can adapt this plan according to how much space you have available in your own yard. Just adjust the size of the various elements.

Develop the plan one part at a time, if you like. You'll most likely want to start with the birdfeeding area, which will give you an immediate payoff.

Make permanent features like arbors and rock walls the first step of each section, to give it structure you can build around. Plant shrubs and trees as soon in your long-range plan as you can, because they will take the longest to fill in.

Features

1. Street
2. Driveway
3. Hummingbird garden
4. Patio with potted fuchsias and geraniums
5. Shade garden
6. Bird feeding area with assorted feeders and a few shrubs
7. Corridor of mixed shrubs and trees, mostly deciduous with a few evergreens
8. Birdseed garden
9. Meadow or prairie garden
10. Sitting place
11. Rock wall (piled or unmortared)
12. Pond and bog garden
13. Naturalistic woodland
14. Brush pile
15. Shallow drinking/bathing station for birds that is made from rock and recirculating pump, including small waterfall for sound of water to attract birds
16. Butterfly garden
17. Grape arbor
18. Berry bushes: thimbleberries, blueberries, viburnums, and elderberries
19. House
20. Huckleberry, lowbush blueberry, and bearberry
21. Evergreen woodland of conifers, rhododendrons, azaleas, and hollies



INSECT POLLINATORS

Bees pollinate about 75 percent of the world's food-crop plants. Most gardeners have no idea of the wonderful variety of bees—over 4,000 species of bees in North America alone. Bumblebees and a large group called "solitary bees," which includes mason bees, leafcutter bees, and squash bees, actually do much more pollinating than honeybees.

Flies are the second most important pollinators. Other pollinators include butterflies, beetles, moths, wasps, and even thrips. For the sake of pollination alone, never kill a bee, fly, or wasp in the garden—unless you're allergic to the stings, or unless it's a deerfly or horsefly that's about to bite you!

SOIL BUILDERS AND GARBAGE COLLECTORS

There is so much to praise about the insects and other creatures that build soil and break down decaying matter in nature and in our gardens. Anyone who has a compost pile has met some of these creatures, including millipedes, centipedes, beetles, sow bugs, and earwigs. They turn yard waste into "black gold."

Keeping Your Good Guys Happy

Once you've planted your beds with a mix of those flowers, herbs, and groundcovers, you can pretty much sit back, relax, and watch the garden happen. The beneficials will control the pests, and your role will be to orchestrate, watch for situations that need extra help, and fine-tune the whole arrangement.

There are some extra things you can do to take care of the beneficial insects in your garden. Beneficials need the same things that all living creatures must have: water, food, shelter, and protection (particularly for breeding). Your garden will provide the food, and it's easy to make sure your beneficials can find water and shelter.

WATER FOR BENEFICIALS

Your companion garden should have water available at all times and at two levels. For flying insects, a waist-height water dish like a birdbath works well. However, while water a few inches deep is perfect for birds, tiny insects may drown in such "deep" water! Give beneficials plenty of places to land by adding rocks and pebbles. (Think of it as providing a beach and towels for your guests.)

For insects that live at ground level, put out a few shallow pans, and add water to them whenever you water your garden. Any container will do, from old pie tins and plastic dishes to nice ceramic bowls. Choose a container with sloping sides and pebbly surfaces so that tiny beneficials have places to alight. If you're concerned about standing water allowing mosquitoes to breed, just stir up the water or refill it often with a vigorous stream of water from the hose.

Other beneficial animals will visit your bug baths too, including frogs, toads, birds, and maybe even a lizard or salamander. All of these will also dine on insects.

FOOD FOR BENEFICIALS

Most beneficial insects need two types of food sources. One is pest insects, so we need to be sure there are some aphids, leafhoppers, plant bugs, slugs, and all kinds of caterpillars around our gardens. This can be tough for gardeners to accept, because who wants bugs in their produce? But if there are *no* pests in your garden, there won't be any beneficials either, and that can leave your crops vulnerable to attack. You'll need to be patient and trust in your unseen army.

To survive when the pest pickings are poor, beneficials will dine on nectar and pollen. The flower and herb "friends" in your companion garden will provide that in plenty.

SHELTERING BENEFICIALS

Be sure that beneficials have places to hide themselves and their eggs around your yard and garden all year. During the garden season, include some permanent plantings in your garden, like a cluster of perennials around a birdbath. Having permanent mulched pathways also shelters many insects like ground beetles.

The tough times to provide shelter for insects are fall and winter, when you want to pull out the spent crops and cut down the dead foliage. Leave some of the perennial foliage standing over winter—it may harbor beneficial insect eggs. You can also create a special mulch boundary around the edge of your garden that won't be dug or tilled. Many beneficial insects will overwinter under mulch or in the soil, and this boundary will give them a place to hide.

BUYING BENEFICIAL INSECTS

Raising beneficial insects for sale to farmers and gardeners is a booming business. You'll see insects for sale in many garden-supply catalogs and at some nurseries. Should you buy

A Changing Landscape

A natural garden is a work in progress, not a finished masterpiece. Its life is interesting, and its face is beautiful, but even when you step back and say "Ahhh," the picture doesn't hold for long. Even the slowest-growing desert landscapes are always changing. Seeds drop and sprout, roots reach out and shoulder neighboring plants aside, voles uproot the groundcovers, birds strip the bark for nest-building—the cycle never ends. Relax and enjoy the process instead of fighting to capture a particular moment. With a natural landscape, instead of a static scene, you can look forward to a lifetime of surprises.

beneficial insects to release in your garden? I say no! I believe on a home-garden scale, we can attract all the helpers we need by planting the right attractant plants and supplying water and shelter.

One case where buying beneficials may help is in home greenhouses or large sunrooms. Gardeners who have indoor gardening areas like these can buy many effective pest controllers. One type is a lady beetle called a mealybug destroyer (*Cryptolaemus montrouzieri*). The larvae of these beetles look like giant mealybugs themselves, with a white, waxy cottonlike coating.

Both the shaggy-looking larvae and the adult beetles dine on mealybugs. They are active only in temperatures above 56°F, and they prefer humid conditions.

CHECKING OUT YOUR BENEFICIAL BUDDIES

How can you tell whether beneficial insects are at work in your garden? One way to tell is by what you don't see. If no holes appear in your plant leaves, it's probably because beneficials are keeping caterpillars, beetles, and other pests at bay.

Another way is to go on a beneficial-insect exploration tour in your garden.

"Backyard Garden Beneficials," is a rundown of 31 kinds of the most common beneficials found in backyard gardens. In this section, you'll find pictures of the insects, tips on identifying them, including their most distinctive features, and the likely spots where they hide in or near your garden. Pick a day when there's not much wind, grab this book or an insect field guide, a magnifying glass or lens (at least 10 power), and perhaps your reading glasses for close-up work.

You may want to keep a notebook to record what insects you see, and on which plants. You can also jot down any questions you have about the insects. One warning here: You may get less "gardening" done if you're like me. The more I look, the less I weed. But then so many of the beneficials are on those "weeds" anyway!

Backyard Garden Beneficials

Once you've planted a companion garden, there will be beneficial insects in it—whether or not you know who they are. In this section, you'll find information and illustrations to help you identify these small, hardworking gardening helpers. You'll also discover how they're helping out in your garden. Check "Special notes" for my somewhat nonscientific interpretations of insect behavior and other tidbits of information I've discovered, plus a few of my own experiences with treasured insect guests. I've grouped the insects by family (like "Beetles" and "Wasps") to make it easy to look up the type of insect you're interested in.

Beetles

Beetles are the largest group of insects—about one-third of all the insects on earth are beetles. Lots of them are beneficial predators and pollinators. Beetles lay eggs that hatch into larvae (an immature stage). After feeding, the larvae pupate, and adults emerge from the pupae. You can often identify a beetle by the straight dividing line that appears to run down its back from head to tail. The line is formed by the folding of the wings. Beetles have two pairs of wings, and both adults and larvae have chewing mouthparts. Beetles may be vegetarians, scavengers, predators, or parasites.

FIREFLIES (*Lampyridae*)

Distinctive features: While they are also called "lightning bugs," fireflies are really beetles. The adults are brown or black, long and flat, with a luminous, blinking organ on the tip of the abdomen. Larvae also glow, and they resemble flat beetles with impressive jaws. Adults are about ½ inch long.

Life cycle: Fireflies lay eggs in the soil, and the larvae hatch and overwinter there. The flashing of fireflies is part of their mating behavior, and there are different blinking patterns for different species.

Where to find them: Firefly larvae favor moist places under bark or debris. The adults are easy to spot flashing on summer evenings, usually at the edge of woods or a field, in your hedgerows, or even in lawn areas under trees.

How they help you: Adult fireflies don't feed, but the larvae are active predators of other insects, slugs, and snails. They hunt at night—just when slugs are also out attacking your garden.

Two beetles are the subjects of old songs, rhymes, and stories—some fanciful, and others based on fact. "Glowworms" (firefly larvae) have a sweet image in the old song, but they are actually fierce hunters. They climb onto the backs of snails. When a snail pops its head out, the glowworm attacks, secreting an enzyme that paralyzes the snail so the glowworm can digest it.

On the other hand, the old poem about the ladybug (really a lady beetle) who's supposed to "fly away home" because her house is on fire and her children are burning is not so far from the truth. It refers to the practice of burning fields to prepare them for replanting. Undoubtedly, lady beetles and lots of other creatures have been destroyed in those fires.

No one's written a song yet about the multicolored Asian lady beetle, but she does have a nickname—the "Halloween Ladybug." That may be because she wears lots of disguises. These beetles can be yellow, orange, or red, with or without spots!

Special notes: Of course, firefly larvae don't really have little lightbulbs inside their bodies. The light they produce is the result of a reaction of special chemical substances in the organ located at the tip of the abdomen. Perhaps it's the inspiration for those glowing plastic cartridges that children love to play with!

GROUND BEETLES (*Carabidae*)

Distinctive features: Ground beetles are shiny and black or brightly colored. Some have prominent eyes, long antennae, and distinct "waists." Ground beetles hide under stones and run quickly when disturbed. Their larvae have distinct segments, strong legs, and visible "jaws" for grasping prey. Some give off strong odors. Adults are ¾ to 1 inch long.

Ground beetle

Life cycle: Some ground beetles lay eggs in small cells made of mud, twigs, and leaves. The larvae may be active predators for about a year, and adults often live from two to three years.

Ground beetle larva

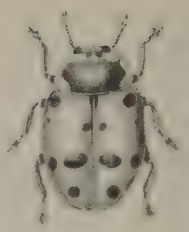
Where to find them: During the day, look for ground beetles under rocks, logs, or boards. If you find them, don't disturb them. They are also attracted to goldenrod, pigweed, groundcovers, and brush. This large beetle family includes over 3,000 species in North America.

How they help you: Adults and larvae are valuable predators of Colorado potato beetles, root maggots, imported cabbageworms, diamondback moth larvae, cutworms, cabbage loopers, asparagus beetles, aphids, flea beetles, gypsy moth larvae, spider mites, tent caterpillars, and many other garden pests.

Special notes: The best way to encourage ground beetles is to maintain perennials, hedgerows, or a small woodpile near the garden. It's best not to handle ground beetles for reasons beyond their fierce-looking jaws (yes, they do nip!). For example, the bombardier beetle (*Brachinus* spp.) emits a little cloud of toxic liquid that can stain your skin. And when disturbed, the green pubescent ground beetle (*Chlaenius sericeus*) gives off an odor that smells like leather.

LADY BEETLES (*Coccinellidae*)

Distinctive features: Also called ladybugs and ladybird beetles, these beetles are dome-shaped and round or oval. They may be red, orange, beige, or yellow, and many have black spots. Many species, such as the 11-spotted lady beetle, have a specific number of spots on their backs. The larvae are dark with orange or yellow marks and have six legs. They're sometimes called "alligators" because they look like alligators in miniature. The pupae are usually dark with orange marks. Adults are 1/16 to 3/8 inch long.



Life cycle: Lady beetles overwinter as adults, usually under leaf or woodpiles or in garden debris. Adults lay clusters of pointed, yellow eggs. The larval stage lasts 20 to 30 days, and the pupal stage, 3 to 12 days.

Where to find them: Every spring, I find handfuls of lady beetles in debris under my tansy and in the groundcover around my lilacs. In early spring they thrive on pollen from dandelions and other flowers. You'll also find them on yarrow, alfalfa, goldenrod, scented geraniums, and all types of daisies. There are over 450 species of lady beetles in North America.

How they help you: Lady beetles are general predators of aphids and many other insects, including thrips, mites, mealybugs, and scale. They also eat the larvae or eggs of many pests. Depending upon the species, adults may eat from 50 to hundreds of aphids per day, and larvae often eat more. (The larva of the common convergent lady beetle, *Hippodamia convergens*, eats its weight in aphids daily.)

Special notes: Lady beetles will often disappear if all the aphids in the area are destroyed, so don't be too quick to spray aphids—even with mild organic controls such as insecticidal soap. To tide them over when insect prey is sparse, maintain permanent plantings of tansy, angelica, and spring-flowering shrubs.

ROVE BEETLES (*Staphylinidae*)

Distinctive features: Rove beetles have short antennae and prominent, pinching jaws used to seize other insects. You might have mistaken them for earwigs. They move rapidly, carrying the tip of their abdomens high above the ground. The gold-and-brown rove beetle is noted for its shiny golden hairs over the abdominal tip. Adults are 1/10 to 1 inch long.

Life cycle: Rove beetles overwinter as larvae, pupae, or adults. They lay eggs in soil or decomposing organic matter such as leaf litter. There can be several generations a year.

Where to find them: Rove beetles seek shelter in dark, damp places, such as compost piles or under leaves, stones, or boards. My garden's wooden pathways offer them a covered bridge for happy hunting. Planting dense groundcovers and providing mulched areas will also help to shelter them. Up to 2,900 species occur in North America.

How they help you: Both adults and larvae are active scavengers, dining on whatever insect larvae and soft-bodied insects they find. They are especially appreciated for consuming root

Continued →

maggots and other fly maggots. (One species studied gobbled up 80 percent of the cabbage maggots in the test plot.) Some species are also parasitoids.

Special notes: These beetles have very sharp jaws that look rather threatening and may be used to pinch you if you handle them. A few also have an extra defense: They can spray a strong, smelly liquid in the direction their tails are pointing. So appreciate these hungry maggot-hunters when you spot them, but don't get too close!

SOLDIER BEETLES (*Cantharidae*)

Distinctive features: These beetles resemble fireflies (without the glow). They are elongated, usually brownish yellow or tan, and display long antennae. The Pennsylvania leatherwing (*Chauliognathus pennsylvanicus*) has a long dark spot at the base of each wing, and the head and area behind the head also have black spots. The downy leatherwing (*Podabrus tomentosus*) is a bluish gray beetle named for its fuzzy, hairy appearance. Adults are ⅓ to ½ inch long.

Life cycle: Adults lay eggs in clusters in the soil, and the larvae live in the soil. There are one or two generations per year.

Where to find them: Milkweed, goldenrod, hydrangeas, catnip, and many other flowers will attract soldier beetles to your garden. You'll spot the beetles frequently on flowers in late summer. The pupae need permanent plantings (perennials, cover crops) where they will not be disturbed. The Pennsylvania leatherwing is found only east of the Mississippi, but many other species are common throughout North America.

How they help you: Adults and larvae are usually predators, feeding on many kinds of insects, including cucumber beetles, grasshopper eggs, caterpillars, root maggots, rootworm larvae, and most soft-bodied insects.

Special notes: If you've had bad cucumber beetle problems in your garden, make a special effort to attract soldier beetles to your cucumbers. Try planting catnip, or let milkweed or goldenrod spring up among your cukes.

To buy and release lady beetles in your garden, thoroughly wet the area where you plan to release the beetles, and release them in the evening. Try putting out a sponge spread with commercial beneficial insect food (available from suppliers of beneficial insects), and release some of the insects under a damp straw mulch. This will maximize the chances that the lady beetles will stay in your garden instead of flying away.

TIGER BEETLES (*Cicindelidae*)

Distinctive features: These big-eyed beetles have long antennae and vary in color from bronze, green, and blue to black. Some have yellow markings. They have long legs and can run fast and fly well. The larvae are noticeably S-shaped, with strong hooklike projections on their abdomens that they use to anchor themselves in the soil while they grab their prey. Adults are ½ to ¾ inch long.

Life cycle: Adults and larvae overwinter in the soil. Females lay eggs singly in burrows in the soil. The larvae dig burrows in open areas from which they hunt. Each generation takes two to three years to complete its cycle.

Where to find them: Tiger beetles move fast, but you may spot them flying or running after predators in sunny, open areas or napping in the sunshine on bare, sandy or dusty spots on pathways or beaches. They also swarm around lights at night. There are about 100 species of tiger beetles throughout North America.

How they help you: Adult tiger beetles eat ants, flies, caterpillars, grasshoppers, aphids, and any other insect that they can catch. The ferocious larvae seize grubs or insects, sometimes even chasing after the prey and then dragging it back to the den for dinner.

Special notes: These beetles and their larvae could star in fast-action movies and exciting chase sequences—if only we could catch up with them! They are rather violent, however. The adult grabs its victim with sharp, sickle-shaped jaws and then whacks it against the ground until it stops moving. As predators go, this one is a real ally for gardeners—but quite a brute! To give tiger beetles a safe spot to overwinter, maintain some perennials, groundcovers, and undisturbed areas around the garden.

Bugs

This group of insects is often referred to as "true bugs" because many people call all insects "bugs." True bugs have shield-shaped bodies with a triangular area on top, above the point where the wings cross. Bugs have mouthparts designed for sucking—some are spearlike, carried under the insects' bodies, but pointed straight out for feeding. Predatory bugs impale their prey and suck out the body fluids. The life cycle includes egg, nymph, and adult stages. The nymphs are often different colors from the adults but change gradually as they molt several times, shedding their outer skins until they emerge as winged adults.

AMBUSH BUGS (*Phymatidae*)

Distinctive features: These aggressive predators have pale yellow or greenish yellow bodies and a wide, dark band across the abdomen. Their well-developed front legs are especially strong for seizing prey. Adults are less than ½ inch long.

Life cycle: Not much is known about ambush bug life cycles. Adult bugs attach their black oval eggs to leaves; nymphs emerge through the tips of the eggs.

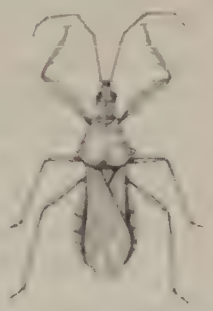
Where to find them: These bugs are masters of camouflage, but I've spotted many on New England asters in the field near my garden. Also look in goldenrod. Ambush bugs are found throughout the United States.

How they help you: Ambush bugs eat flies, butterflies, day-flying moths, and other bugs. Beekeepers consider ambush bugs pests because the bugs eat bees.

Special notes: Ambush bugs get their name from their behavior of lying in wait in flowers and snatching victims that fly near. An ambush bug injects its prey with saliva, which paralyzes the victim so the bug can feed without struggle.

ASSASSIN BUGS (*Reduviidae*)

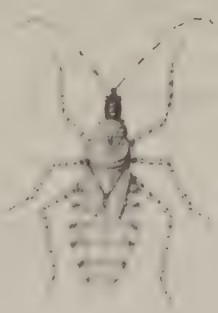
Distinctive features: These long, oval bugs have thin heads that look stretched out. They have large eyes and spiny front legs that are very powerful—they use the legs to grasp prey. The adult bugs have curved mouthparts that are carried under their heads. There are several kinds in several colors, from dull brown through yellow, green, or black. The nymphs are often brightly colored, in shades of red. The adults are usually ½ to ¾ inch long.



Assassin bug

Life cycle: Assassin bugs overwinter as adults, nymphs, or eggs in garden litter, fields, or beneath perennial plantings. Depending upon the species, the complete life cycle takes one year or more.

Where to find them: Assassin bugs frequent meadows, fields, and gardens. Watch for them in your hedgerows, perennials, or groundcover plantings. You may spot their eggs—rusty-colored bundles topped with white caps—on leaves or in the soil. Assassin bugs are common throughout North America.



Assassin bug nymph

How they help you: Assassin bugs eat aphids, leafhoppers, flying insects (including bees), asparagus-beetle eggs and larvae, and other beetle larvae.

Special notes: Assassin bugs are fun to spot but not to handle. They can inflict a nasty bite that really hurts!

BIG-EYED BUGS (*Lygaeidae*)

Distinctive features: These tiny oval bugs are named for their huge eyes that point sideways. They are off-white through tan, gray, and brown, with small black spots on head and thorax. The bugs drop to the ground when disturbed. The eggs have distinctive red spots and are laid singly. Adults are ⅛ to ¼ inch long.

Assassin bugs come in a variety of colors and shapes. Some are long and stretched out like walking sticks; others are oval or rectangular. The wheel bug (*Arilus cristatus*) is huge (1⅛ to 1⅜ inches long) and can capture and devour large caterpillars such as tomato hornworms. Wheel bugs also eat Japanese beetles and European chafer beetle larvae. They are found east of the Rocky Mountains.

A small assassin bug, called the bee assassin, is more common in the western United States. It is generally red with black or brown markings, or brown with yellow marks. It's not popular with beekeepers, because it attacks honeybees along with a variety of other insects.

Life cycle: Adults overwinter in garden litter. They eat nectar and seeds when prey isn't available. There are several generations per year.

Where to find them: Look for big-eyed bugs under potato plants, clover, and other low-growing groundcovers or cover crops. The best-known species (*Geocoris* spp.) of big-eyed bugs is common in southern states north to Maryland, and in California.

How they help you: Big-eyed bugs prey on insect eggs, aphids, blister beetles, leafhoppers, and spider mites. Nymphs and adults can eat several dozen spider mites per day. Effective control for corn earworm eggs.

Special notes: The big-eyed bug isn't found where I live in western New York, but many of its relatives are found here. The big-eyed bug belongs to the insect family called "seed bugs." Its members eat seeds—hence the name—but many are also predators. If you have a butterfly garden with milkweed in it, you are sure to find the small eastern milkweed bug (*Lygaeus*), which has a bright red X on its black body.

DAMSEL BUGS (*Nabidae*)

Distinctive features: Damsel bugs are fast-moving, thin, gray or brown insects with curving, needle-like beaks, powerful forelegs, and threadlike antennae. The wingless nymphs look similar to but are smaller than adults. Adults are ⅜ to ½ inch long.

Life cycle: Adults overwinter in weeds, alfalfa, or grain fields and lay eggs in spring. Nymphs emerge after one week and dine on other insects. There are one or two generations per year.

Where to find them: Look carefully under groundcovers or cover crops, especially alfalfa and clover, for these small, nondescript insects. The only place I've found them is in my neighboring farmer's alfalfa field. Damsel bugs are found throughout North America.

Continued ➔

How they help you: These little hunters are not frail "damsels in distress." In fact, they cause distress to aphids, caterpillars, thrips, leafhoppers, treehoppers, mites, redheaded pine sawflies, and plant bugs.

Special notes: If you find damsel bugs in nearby fields, try moving them into your garden—perhaps to beds of tomato plants underplanted with clover. Handle them carefully! These not-so-ladylike damsels can inflict a painful bite.

MINUTE PIRATE BUGS (*Orius* spp.)

Distinctive features: To the unaided eye, these tiny bugs just look like black dots. With a magnifier, you'll see their oval black bodies with a black-and-white pattern of triangles, and very small heads. Nymphs are pinkish, yellow, or tan and have red eyes. Adult bugs are ¼ inch long.

Life cycle: Adults overwinter under perennials or groundcovers. Females lay eggs on stems and leaves. Nymphs feed on insects for two to three weeks. There are three or four generations per year.

Where to find them: Minute pirate bugs like the shelter of corn, alfalfa, clover, and vetch. Try looking for them on white flowers because it's easy to spot the black bugs against the white flowers. I found them gobbling thrips on daisies in my garden. Minute pirate bugs are found throughout North America.

How they help you: One research study counted over 50 varieties of prey for these active predators! Both adults and nymphs kill large numbers of aphids, thrips, leafhoppers, corn earworm eggs, and spider mites.

Special notes: Minute pirate bugs are sold commercially for greenhouse use in Europe and the United States, especially for thrips control.

SPINED SOLDIER BUG (*Podisus maculiventris*)

Distinctive features: These shield-shaped bugs may be yellow, beige, or brown, with black speckles. They have long snouts that point straight forward. Their pointed shoulders—like a soldier's uniform with epaulets—distinguish them from a pesty relative, the stink bug. Adults are ½ inch long.

Life cycle: Adult spined soldier bugs overwinter under permanent plantings and lay eggs on leaves in spring. Nymphs start out eating plant juices or water but soon become predators. After six to eight weeks, they reach adult stage and continue feeding for another month or two. There are up to two generations per year.

Spined soldier bug

Where to find them: In my garden, spined soldier bugs are easy to spot on, around, and under tansy! Also look for them on other flowering perennials. Spined soldier bugs are found throughout North America.

How they help you: These busy predators eat lots of pests, especially larvae of Mexican bean beetles and Colorado potato beetles. (Commercial growers even use them.) Other prey include European corn borer larvae, corn earworms, armyworms, imported cabbageworms, sawfly larvae, and—unfortunately—even a few beneficials, such as lady-beetle larvae.

Special notes: You can buy a special attractant substance called a pheromone to lure spined soldier bugs to your garden—but I'll bet you won't have to in your companion garden. Tansy does the job just fine.

TWO-SPOTTED STINK BUG (*Perillus bioculatus*)

Distinctive features: This bug is also called the conspicuous stink bug, and it's easy to see why. This fellow really stands out with his shield-shaped, black body with a wide, curved, orangey band across the back. Nymphs are red and black. Adults are ⅜ to ½ inch long.

Life cycle: Females lay gray eggs in clusters on the undersides of leaves. There are two or three generations per year.

Where to find them: Look for two-spotted stink bugs in weedy areas, where they feed on plant juices to supplement their diet of insects. You may also spot them in your asparagus bed. These bugs occur throughout the United States.

How they help you: Nymphs and adults consume eggs or larvae of Colorado potato beetles, Mexican bean beetles, asparagus beetles, and cabbage loopers.

Special notes: One study on two-spotted stink bugs showed that they reduced Colorado potato beetle populations by up to 60 percent. It would be especially helpful to lure two-spotted stink bugs to your potato patch, asparagus bed, or cabbage neighborhood.

Dragonflies

Dragonflies are long, slender insects with large, compound eyes that nearly cover the head or bulge out to the side. They have sharp, biting mouthparts and can eat their prey while in flight. All have four strong wings that move independently and can propel the insects forward or backward. Immature dragonflies, called *naiads*, are powerful predators that capture aquatic insects—and even small fish—by using a bristly lower "lip" that emerges at lighting speed to grasp the prey. This group of insects also includes damselflies. There are about 5,000 species worldwide and about 450 in North America.

DARNERS (*Aeschnidae*)

Distinctive features: Darners are the fastest, largest dragonflies. They are usually green, brown, or blue, and have large, clear, finely netted wings that can span up to 5 inches in some species. Their large compound eyes meet on top of their heads. Their wings remain outstretched at rest. Adults are 2¾ to 3⅛ inches long.

Life cycle: Females hover above water and thrust their eggs below the surface, usually into slits in the stems of submerged plants. The nymphs, or naiads, live in water and crawl out in early spring or late summer to transform into adults.

Where to find them: Darners may lay their eggs in small ponds or even backyard water gardens. You may find the nymphs under stones or debris near water gardens or small streams. Brown darners (*Boyeria vinosa*) occur throughout most of the eastern United States. Green darners (*Anax junius*), also called darning needles, are common throughout most of North America.

How they help you: Darners prey on mosquitoes, bees, and many flying insects. Larvae eat mosquito larvae and other aquatic life.

Special notes: You may have a chance to witness the transformation of a darner naiad into an adult. The naiads emerge from the water—sometimes traveling only 1 foot from the edge—and split their skins down the center of the body so the adult can emerge. If you're interested in attracting darners, be sure your water garden has an appropriate open "shore" where the nymphs can emerge.

NARROW-WINGED DAMSELFLIES (*Coenagrionidae*)

Distinctive features: Narrow-winged damselflies are brightly colored, often shiny blue or blue-green. They have two pairs of wings that taper to a narrow stalk at the base. They hold their wings vertically over their bodies when at rest. The nymphs, or naiads, live in water, using their fishlike gills to propel themselves. Adults are 1 to 2 inches long.

Life cycle: Females deposit eggs on plants above or below the water surface. The nymphs capture aquatic insects and tadpoles until fully grown. Adults of many species emerge from the water in July or August.

Where to find them: A backyard pond, water garden, or bog garden will attract damselflies. Since they are not strong fliers, adult damselflies usually stay close to a water source. You'll find nymphs of many species in quiet or slow-moving water.

How they help you: Naiads dine on many aquatic insects, including mosquito larvae. Adults are general predators who eat many other insects. They are especially effective at controlling aphids. Most North American damselflies belong to this family.

Special notes: Some familiar damselflies are nicknamed for their colors. Doubleday's bluet (*Enallagma doubledayii*) has a bright blue body. The red bluet (*Enallagma pictum*) has a bright red, reddish yellow, or brown and yellow body. If you live in the Northeast, you might have met it personally, as it often alights on a person's shoulder to nibble gently and harmlessly on clothing.

Lacewings

The scientific name for this group of insects, *Neuroptera*, comes from the network of veins in the transparent wings of its members. There are over 300 species in North America.

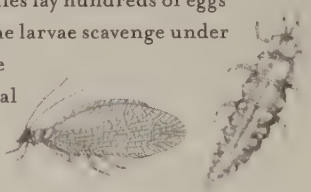
Damselflies and dragonflies mate in flight, and you may spot mating pairs flying together near ponds and water gardens. The males may also assist the females when it's time to lay eggs. The male holds the female while she dips her abdomen into the water to deposit the eggs. Then, like a helicopter, the male lifts the female straight up and away from the water's surface. In another species, the male and female submerge themselves in the water for up to 30 minutes in order to lay eggs.

The ones we meet most often are lacewings, mantidflies, and antlions. Brown and green lacewings are generally considered the most valuable predators of garden pests. Insects in this order have two pairs of long, oval wings, which they hold like a tent over their bodies when at rest. They have chewing mouthparts, and the larvae are mostly predators.

BROWN LACEWINGS (*Hemerobiidae*)

Distinctive features: These delicate insects have brown, transparent, netted wings covered by fine hairs. Their eggs are cream-colored ovals laid directly on the undersides of leaves. The larvae often camouflage themselves with debris, earning them the nickname of "trash collectors." Adults are ¼ to ⅜ inch long.

Life cycle: In the spring, females lay hundreds of eggs on the undersides of leaves. The larvae scavenge under organic matter for one to three weeks. Some species have several generations in a year.



Lacewings have a funny-looking relative known as the "antlion" or "doodlebug" (family *Myrmeleontidae*). Adult antlions are about 1½ inches long and resemble dragonflies. The bug's whimsical name may be due to the appearance of the larvae, which have an oversized head, short legs, and a bristly body. They also walk backward. This fellow is not funny to an ant, however, as its long spiny jaws are lethal. Antlions make pits in the sand, where they lie in wait for ants or ticks. When the ants pass by or fall in, the antlion consumes them. They are found mainly in dry, sandy soil in sheltered spots in the southern and southwestern United States.

Continued

Where to find them: Adult brown lacewings fly in the evening and night, mostly in woods, orchards, or fields. Try poking under some leaves in these areas, and you may find the spindle-shaped larvae, fuzzy with organic "trash," just trundling along. Brown lacewings occur throughout North America.

How they help you: Both adults and larvae are generalists, eating aphids, mealybugs, nymphs of scale insects, and other soft-bodied insects. A single lacewing larva consumes 100 to 600 aphids in the course of its development.

Special notes: Brown lacewings are often described as shy or secretive, and not much is known about how effectively they control pests in gardens. However, they are effective aphid predators and are beneficial wherever they occur.

GREEN LACEWINGS (*Chrysopidae*)

Distinctive features: These pale green to bright green insects have transparent wings, which they hold upright over their small bodies. They also have golden or copper-colored eyes. The larvae have prominent pincers, and their bodies are patterned in pinkish brown and cream spots. Adults are 3/8 to 5/8 inch long.

Life cycle: From spring into summer, females lay eggs on leaves near aphids. When the larvae emerge, they eat anything in reach. After two to three weeks, they pupate in round silken cocoons attached under leaves. New adults emerge one to two weeks later. Most overwinter as adults, often in clusters, in dry, dark, protected places. There are two or three generations per year.

Where to find them: You may spot green lacewings flying about in the evening in late spring or late summer, especially around meadows or forest edges. Try looking in your corn patch, too. You will recognize the creamy pinhead-sized eggs the moment you see them—with the help of a magnifying glass. Each egg is suspended on a delicate filament attached to a leaf or twig. Lacewings supplement their insect diet with nectar, so you may also find them on yarrow, angelica, Queen Anne's lace, sunflowers, and scented geraniums. Green lacewings occur throughout North America.

How they help you: Some research counts show that lacewing larvae eat 100 to 600 aphids before reaching the adult stage. They eat thrips, mites, whiteflies, and eggs of many pests, including leafhoppers, cabbage loopers, Colorado potato beetles, and asparagus beetles. They also eat small caterpillars and beetle larvae. They are used commercially in greenhouses, vineyards, and fields.

Special notes: There are pros and cons to aggressive predators like the lacewing larvae. For one thing, they emerge from their eggs ready to eat everything—including each other. That must be why Mother Nature designed lacewing eggs on isolated filaments. It gives each nymph a chance to eat some aphids before a "sibling" gobbles him up! For commercial sale, each lacewing egg is packed in an isolated cell to prevent cannibalism if the eggs hatch en route.

Flies

Swatting flies may be fine in your kitchen, but don't kill any flies in your garden! With the exception of a few biters like horseflies, deerflies, and mosquitoes, most garden flies are either valuable pollinators, predators, or parasitoids—and several are all of the above. Flies have only two wings (one pair). Their life cycle includes egg, larval, pupal, and adult stages. Predatory flies have piercing mouthparts for attacking their prey and feeding on their body fluids.

APHID MIDGES (*Cecidomyiidae*)

Distinctive features: These tiny flies, also called gallflies, resemble mosquitoes. They have long spindly legs, long antennae, and fragile bodies. The larvae are bright orange. Adults are 1/16 inch long.

Life cycle: Aphid midges overwinter as larvae in little cocoons in soil, emerging in late spring to search for aphids. Female midges lay up to 250 tiny orange eggs on leaf surfaces near aphids. There are several generations per year.

How they help you: One species of aphid midge (*Aphidoletes aphidimyza*) is widely used in the greenhouse industry in Europe, Canada, and parts of the United States to combat many kinds of aphids. One larva alone can eat 10 to 80 aphids before pupating. In gardens, aphid-midge larvae eat cabbage aphids and many others. Related species also attack mites, mealybugs, and other soft-bodied insects.

Where to find them: Look for tiny, bright orange larvae all over the flowers that aphids like most, including roses, especially in mid- to late summer. The adults fly at night, perhaps seeking pollen and nectar, so go searching for them with a flashlight. You may even catch a glimpse of "the mating dance," which looks like a tight little cluster of bodies just suspended in midair. Aphid midges occur throughout North America.

Special notes: Since there are many generations of aphid midges in a season, you must keep the "honeydew" coming. Choose a variety of long-flowering herbs and flowers, including Queen Anne's lace, dill, thyme, and wild mustard. The pupae need undisturbed soil or groundcovers, so provide permanent plantings such as wildflowers, perennials, and shrubs. Aphid midges thrive in high humidity and temperatures from 60° to 80°F.

HOVERFLIES (*Syrphidae*)

Distinctive features: These flies are often mistaken for bees because they have black-and-yellow or white-striped bodies. You can tell the difference by the pattern of movement; hoverflies hover outside of flowers and dart quickly in and out, while bees alight on flowers and stay awhile. Larvae are pale, greenish brown, sluglike maggots. They leave a dark, oily excrement behind. Hoverflies are also called flower flies or syrphid flies. Adult hoverflies are 1/2 to 5/8 inch long.

Bug zappers are marketed as control devices for mosquitos, gypsy moths, blackflies, and other pest insects. However, what they *really* kill are lots of innocent night-flying insects. Scientists at the University of New Hampshire who conducted "zapper counts" found dead lacewings as well as parasitic wasps that control gypsy moths and other caterpillars. They also found predatory beetles that prey on pest caterpillars. Other victims were caddis flies (an essential link in the ecology of ponds and streams) and beautiful large moths such as luna and cecropia moths that burned their wings in the zapper and were left flopping helplessly on the ground.

Ironically, bug zappers do little or nothing to decrease mosquito or gypsy moth populations. So zappers have no place near your garden—or anywhere else!

Life cycle: Hoverflies overwinter as pupae, attached to plants or hidden in soil. The female hoverfly lays individual eggs on leaves near aphid colonies. Larvae emerge about three days later. There may be five to seven generations per year, depending upon availability of aphids.

Where to find them: You can find the sluglike larvae wherever aphids are abundant. Hoverfly adults require nectar and pollen and are attracted to a variety of flowering plants and herbs, such as yarrow, Queen Anne's lace, wild mustard, horseradish, and feverfew. Hoverflies occur throughout North America.

How they help you: The adults are important pollinators, and the larvae are effective predators of aphids, leafhoppers, scale, mealybugs, thrips, corn borers, and corn earworms. One larva can consume aphids at a rate of 1 per minute, or up to 400 aphids in its larval stage, depending upon the species.

Special notes: Hoverfly larvae may be scavengers, parasites, or plant eaters. One type, the narcissus bulb fly (*Merodon equestris*), produces larvae that damage spring bulbs. However, the rest of the family make up for this troublesome relative. Larvae of the American hoverfly (*M. americanus*) and the flower fly (*Toxomerus* spp.) are probably as important as lady beetles in controlling aphids.

ROBBER FLIES (*Asilidae*)

Distinctive features: Some species of robber flies resemble bumblebees, and others look like damselflies. All have strong legs with which to hold their prey. They also have bearded faces with a hollowed-out area between the eyes. Many are gray and very bristly or hairy. The long, cylindrical larvae taper at each end. Adults are ½ to ¾ inch long.

Life cycle: Robber flies overwinter as larvae. The larvae pupate in the soil. When the adults emerge, they must feed on both nectar and insects before they can reproduce. There is one generation per year.

Where to find them: Check in decaying wood or in the soil for robber fly larvae. When you're working in your garden, watch for flying insects that drop down on other insects from above—they're robbers! Robber flies are found throughout North America.

How they help you: Robber flies are aggressive predators of all kinds of insects, including beneficial ones. They attack butterflies, grasshoppers, wasps, bees, and flies. Larvae in the soil attack grubs, root maggots, and insect eggs.

Special notes: Robber flies were surely named by somebody under the influence of old Robin Hood stories who imagined the flies as daring, bearded robbers leaping down on unsuspecting passersby. These flies really look like robbers! Some are short and stocky, and others are thin with narrow "waists"—and they all have that hairy-looking face. The indentation between the eyes (they have *three*) definitely gives them a villainous look. Add to that the tendency to jump on their victims, and you indeed have a drama with a well-cast robber—only *we* know he's good!

TACHINID FLIES (*Tachinidae*)

Distinctive features: Flies from this large family are usually stocky, with coarse bristles around the abdomen. They resemble large houseflies with mottled black, grayish, tan, or reddish brown bodies. Adults are ⅓ to ½ inch long.

Life cycle: Adults lay eggs on the bodies of other insects. The larvae feed inside the host insects, usually killing them. The larvae then drop to the soil to pupate. (Some pupate inside a host body.) Adults feed on nectar and usually fly from late spring to late summer. There may be several generations per year.

Where to find them: Look for white eggs on caterpillars or true bugs; these eggs are a clue that tachinid flies or other parasitoids have been there. You'll often spot adult tachinid flies on wildflowers and herbs in meadows and fields. I've seen them on tansy and Queen Anne's lace in my garden. Tachinid flies occur throughout North America.

Tachinid fly

How they help you: Many kinds of tachinid flies are effective parasitoids of vegetable crop pests, including European corn borers, corn earworms,

Continued

Even if you never studied entomology in school, you can figure out lots of things about insects and their behavior just by taking a close look. For example, some predatory flies (especially hoverflies) look rather like bees because they have black-and-yellow stripes. But it's easy to separate the flies from the bees by counting their wings.

Flies have only two wings, while bees and wasps have two *pairs* of wings. (Counting the number of wings on a flying insect is tough when the insect's in flight but quite easy when it's resting on a leaf or flower.)

As for insect behaviors, I think one of the most interesting beneficials to watch in action is a tachinid fly. I often spot these flies searching for a host on which to lay eggs—walking rapidly, and with what seems like great determination, over soil and plants. When the fly spots its target, the fly signals its intent by hopping and circling around its prey.

The caterpillars and beetles that the fly attacks also enact their individual dramas clearly. They make agitated movements to try to avoid the fly's attack and will also try to remove fly eggs by wiping their legs along their bodies.

imported cabbageworms, cabbage loopers, cutworms, armyworms, Colorado potato beetles, stink bugs, squash bugs, tarnished plant bugs, and cucumber beetles.

Special notes: Some flies are fairly general in their choices of targets, while others have specific hosts. Studies on pest control using tachinid flies show varying success rates. As with many efforts at natural pest control, one beneficial insect or pest-management strategy may not be enough—but collectively, tachinids are part of a winning team.

Mantids

There are 11 species of mantids in North America, and 1,800 around the world, but we are most familiar with the praying mantis. All mantids have long bodies and "praying" forelegs with spines that help to capture prey. Mantids have necks that seem to rotate so that the insect can look behind itself. They can be as small as 3/8 inch or as large as 6 inches.

PRAYING MANTIS (*Mantis religiosa*)

Distinctive features: These familiar garden insects get their name from their tendency to hold their forelegs up "in prayer." They are about 2 inches long, are green or tan, and fly very well. They are experts at camouflage, often matching their choice of habitat plant to their bodies.

Life cycle: Females attach flat egg masses, which resemble papier mâché, to twigs or fence posts, where they overwinter. Up to 200 nymphs hatch in the late spring and proceed to eat everything in sight—including each other! The lucky ones blow off on a breeze and take over a new territory, which they dominate for their one-year life cycles.

Where to find them: Since they are territorial, you won't usually see more than one praying mantis in your garden. I've spotted a praying mantis on borage and goldenrod, but they may choose any garden or meadow plants as hunting grounds. Praying mantids are found in the southern and eastern United States and north into Ontario.

How they help you: Mantids are voracious hunters and truly undiscriminating predators of anything they can catch in their powerful forelegs. While you can buy praying mantis egg cases, I think they're a dubious purchase. However, naturally occurring mantids probably help to control pests in the garden, especially if there's a serious outbreak and the pest is abundant.

Special notes: The common praying mantis is from Europe, accidentally introduced in 1899 on nursery stock. The Chinese mantis was also introduced in 1896, and is found in the eastern United States. The narrow-winged mantis was brought in from southern Asia in 1933 and has naturalized in Delaware and Maryland. All are considered beneficial.

Mites

Mites are not insects, but they are another type of tiny creature that plays important roles in the garden. Some are plant pests, but many are also important predators of garden pests. Mites are eight-legged, flat-bodied organisms that look somewhat like very small spiders. There are about 30,000 named species of mites in the world—and lots more still to be named! One way to tell a spider from a mite is that the spider appears to have a "waist"—actually a division between the upper body and abdomen. With mites, you can't distinguish the two body parts.

Mantids would surely win gold ribbons in the Insect Olympics. A praying mantis can make two strikes with its forelegs in a fraction of a second. A mantis's jaws are strong enough to crack the hard shells of most insects. Some mantis species have even captured small frogs, lizards, and hummingbirds! Luckily, those are not the species you'll find in your garden. In the United States, the biggest mantis is the Chinese mantis—only about 3 inches! By the way, although mantids won't wrestle us to the ground, they will nip—so proceed with appreciative respect!

PREDATORY MITES (*Phytoseiidae*)

Distinctive features: Predatory mites are nearly invisible to the naked eye. Even with a magnifying glass, all you'll see are tear-shaped, pale or reddish brown dots.

Life cycle: Adult mites hibernate in debris or under bark. Predatory mite species complete their entire life cycle in only a few days, so there are many generations per year.

Where to find them: You probably won't see mites around your garden because they're so small. Pollen-rich plants may help to maintain some predatory mites, and one study shows that bell peppers (which have pollen-rich flowers) maintained one species.

How they help you: Predatory mites attack spider mites, thrips, or fungus gnats. They may attack adults, nymphs, larvae, or eggs. Predatory mites are found throughout North America.

Special notes: Several kinds of predatory mites are sold for pest control. One success story is *Amblyseius fallacis*. This all-purpose mite preys on many harmful spider mites and can be released in strawberries, raspberries, orchards, bedding plants, and in ornamental plantings. If you buy garden plants at a greenhouse this year, ask the manager if she has worked with any "mighty mites" lately.

Spiders

Many people are scared of spiders, but in the garden, they're nothing to fear—unless you're an insect looking for plants to munch on! Spiders belong to a group of organisms called arachnids, having eight legs and two body parts. Most spiders have eight simple eyes. There are about 3,000 species of spiders in North America. Studies of spiders in agricultural crops show their pest-control value in crops as diverse as potatoes, rice, and cotton. Home gardeners can encourage them by providing mulch—especially straw—and a diversity of flowers. Although they have jaws, very few spiders bite people. In fact, even the most dreaded spiders, such as tarantulas and black widows, attempt to avoid and escape from humans rather than attack.

CRAB SPIDERS (*Thomisidae*)

Distinctive features: These small spiders skitter sideways, backward, or forward, like crabs. They are usually short and wide, with the second pair of legs longer than the others (also giving that "crab-claw" appearance). There are 200 North American species, so crab spiders come in many colors, many of them camouflaged to match their preferred plant hiding places. Adults are ½ inch long.

Life cycle: Crab spiders don't spin webs. Instead, they search out their prey on plants, both day and night. They usually wait for prey on flower heads. The female produces eggs in silken sacs, which she protects until she dies, usually before the spiderlings emerge.

Where to find them: These spiders often hide in flower heads, waiting for flying insects. Many species prefer yellow and white flowers, such as cosmos, daisies, and goldenrod. Crab spiders are found throughout North America.

How they help you: Crab spiders are generalists and will capture any insect that passes by them.

Special notes: Some crab spiders are named for their looks. The goldenrod spider (*Misumena vatia*, sometimes called "flower spider" or "red-spotted crab spider") often hides out on goldenrod or daisies, changing its color to yellow for camouflage. The thrice-banded crab spider (*Xysticus triguttatus*) is brown, black, and white, with dashed lines across its lower abdomen.

In the fall, thinking about pest control is usually low on our list of priorities. Your attitude may be "what's done is done," and you'll tackle next year's pest problems next year. But fall garden cleanup can make a big difference in next year's pests. I'm not just talking about raking and cleaning up garden debris. This time, I mean hiring—actually *buying*—some beneficial mites to do the job for you.

If you've had problems with spider mites in your garden, especially in your strawberries, you can get help from *Amblyseius fallacis*, a beneficial mite that is used widely in commercial crops. When released in the fall, the mite will also wipe out mites in your home garden. It will overwinter, too, and become active in spring.

ORB WEAVERS (*Araneidae*)

Distinctive features: Orb weavers may be various shades of brown and orange, with dark brown bands and markings. They hang head downward in large webs (up to 20 inches across). They often have a cross-shaped mark on the abdomen, inspiring the common name "cross spider." Orb weavers have eight eyes in two horizontal rows with four eyes in each row. Adults are 1/16 to 1 1/8 inches long.

Life cycle: Orb weavers make symmetrical five- or six-sided webs every night, eating the remains of the previous night's web. Females attach egg masses to plants at the sides of the webs.

Where to find them: You'll find orb weavers stretching webs between plants in your garden or between foundation shrubs and your house. This huge family includes several hundred species in North America, among them our familiar garden spider (*Araneus diadematus*) of the northeastern United States.

How they help: Garden spiders and other orb weavers catch all sorts of flying and jumping insects, including grasshoppers, flies, and moths.

Continued ➔

Special notes: Some orb weavers are recluses, hiding in caves and dark places. One of these is the barn spider (*Araneus cavaticus*), which spins its webs in barns, caves, or other shady locations. Another spider that is quick to hide is the black-and-yellow argiope (*Argiope aurantia*), which drops to the ground when disturbed. It likes sunny, quiet places with no wind. I've spotted them on warm afternoons in my sunny perennial border.

Spiders are remarkably ingenious at spinning webs suited to their style of hunting and self-protection. Sheet-web weavers (*Linyphiidae*) make flat or dome-shaped "sheets." One species is called a hammock spider because it stretches its sheet between fence posts or branches. Funnel web weavers (*Agelenidae*) make webs that "funnel" the prey down to the hungry spider at its base. No matter the style, if you see a web, just let it be—you have a garden helper somewhere nearby.

WOLF SPIDERS (*Lycosidae*)

Distinctive features: These brown or gray spiders are called wolf spiders because of their coloration and hunting technique. They have eight dark eyes arranged in three rows, the first row having four eyes. Depending on species, adults are from ⅛ inch to 1⅛ inches long.

Life cycle: Not web spinners, wolf spiders live mostly on the ground, some digging burrows for retreat. Females carry or drag their egg sacs or transport their young on their backs.

Where to find them: I see these spiders regularly when I move mulch under flowers or vegetables. I sometimes disturb a mother with her egg sac. You will also see wolf spiders basking in the sun or sitting with egg sacs in the "doorways" of burrows. There are 200 species ranging throughout North America.

How they help you: These general predators hunt at night, eating all kinds of insects, including aphids, mites, flies, moths, and beetles.

Special notes: Thin-legged spiders (*Pardosa* spp.) are the largest group of wolf spiders (about 100 kinds in North America), and only a specialist can tell them apart. The clue to identifying a spider as a wolf spider is its long-legged, thin look, dark color, and long pale, dark stripes running from head to abdomen.

Wasps

Wasps belong to an insect group that also includes bees, ants, and sawflies. All wasps have a narrow "waist" and two pairs of membranous wings. Adult wasps have chewing mouthparts and some have tonguelike structures they use to drink nectar. Females of most species have a stinger. Their life cycle includes eggs, larvae, pupae, and adults. Most wasps are beneficial as pollinators or as predators or parasitoids of insect pests. There are thousands of species of wasps in North America, so just a few of these outstanding beneficials are listed here!

APHIDIID WASPS (*Aphidiinae*)

Distinctive features: These wasps are tiny and black, with long antennae. Adults are ⅛ inch long.

Life cycle: Most species lay hundreds of eggs, each in the body of an aphid. The larvae eat the contents of the aphid and pupate inside the dead aphid's body. The new adult wasp cuts a hole in the aphid body and emerges, leaving a shell behind. Adults live one to three weeks, and there are several generations each year.

Where to find them: Aphidiid wasps show up wherever there are aphids and supplemental nectar and pollen, but they may be hard to spot. Look for the empty shells of dead aphids, called "mummies," on plant leaves—they look like beige, papery sacs. Aphidiid wasps are found throughout the United States.

How they help you: Scientists report that aphidiid wasps are effective controls for summer and fall aphid infestations, more so than early-season aphids. Females of some species can parasitize hundreds of aphids a day. Most of those aphids then die before reproducing. Studies show significant success in controlling pea, bean, melon, potato, cabbage, and green peach aphids.

Special notes: Many aphidiid wasps are sold commercially and are one of the best success stories in greenhouse organic pest management in the United States and Europe. *Aphidius colemani* and *A. matricariae* can prevent problems with up to 40 kinds of aphids. Best of all, the wasps are able to establish themselves in most regions of the United States and can overwinter. To encourage them in your garden, maintain wildflowers and perennials, including herbs of the carrot family such as dill, Queen Anne's lace, fennel, and coriander.

One little wasp has really earned star billing for over 60 years of greenhouse heroism. It's *Encarsia formosa*, the terror of greenhouse whiteflies. This pinhead-sized wasp isn't native to the United States, but it's now being raised commercially and has become established in some areas of the United States. These wasps need warm, humid climates, cannot tolerate any pesticides, and require a ready supply of whiteflies—something that many greenhouses have all too often!

BRACONID WASPS (*Braconidae*)

Distinctive features: These small black or brown wasps look like flying ants. The wasps have a long, tubelike protrusion beneath the body called an ovipositor (it's used to place eggs).

The cocoons look like white bumps on the bodies of parasitized caterpillars. Adults are up to 3/8 inch long.

Life cycle: Adult wasps insert eggs into a host egg, larva, pupa, or adult. The larvae develop inside the host's body and then form cocoons. The whole life cycle may be from 20 to 50 days.

Where to find them: When you see white cocoons attached to caterpillars, beetle grubs, and fly larvae, it's evidence that braconid wasps are at work in your garden. It's estimated that there are over 1,900 species of braconids in North America.

How they help you: Studies of braconid wasps in corn and cabbage crops show that they're effective against European corn borers, cabbage maggots, and diamondback moths. Other prey include tent caterpillars, gypsy moth caterpillars, tomato hornworms, and armyworms. Some species of braconids are commercially available.

Special notes: Braconid wasps benefit from flowering plants beginning in spring, such as sweet alyssum.

CHALCID WASPS (*Chalcididae*)

Distinctive features: Chalcid wasps are tiny black wasps. Through a magnifying glass, they may be metallic blue, green, or yellow. The tubelike structure called an ovipositor is not visible in chalcid wasps, so that's one way you can distinguish them from braconid wasps. Some chalcid wasps "play dead" if they are disturbed. Adults are 1/16 to 3/8 inch long.

Life cycle: Female wasps lay one or two eggs in the skin of a caterpillar. The larvae feed inside the caterpillar, pupate, and emerge. Some species lay eggs that develop into up to 1,000 larvae each. Adult wasps feed on nectar or honeydew (a secretion given off by aphids and some other insects).

Where to find them: You may spot chalcid wasps anywhere around your garden or in permanent plantings. Chalcid wasps are found throughout North America.

How they help you: Chalcid wasps feed on a wide range of pests, including aphids, whiteflies, leafhoppers, caterpillars, and scale.

Special notes: Some experts regard chalcid wasps as more significant controls for pests than braconid or ichneumonid wasps because chalcids can produce so many larvae from just one egg. It's an unusual asexual type of reproduction called hypermetamorphosis!

ICHNEUMONID WASPS (*Ichneumonidae*)

Distinctive features: This is one parasitoid you can see easily! The females often have a huge, dangling, tubelike structure for laying eggs (an ovipositor) that is even longer than her long antennae and legs. Colors vary through reds and browns. Adults vary in size from 1/8 inch up to an impressive 1 5/8 inches.

Life cycle: Female wasps inject eggs into hosts—usually caterpillars. The wasp larvae slowly consume the host until the adult wasps emerge.

Where to find them: I have seen ichneumonids on window screens or around the porch light on a summer evening (another good reason to ban bug zappers!). You may also find a dried-up caterpillar or cocoon with another cocoon inside. The inner cocoon harbors an ichneumonid. The adults need nectar and water. They'll frequent your bug bath as well as parsley family plants like tansy, lovage, dill, and sweet cicely. There are over 3,300 species in North America.

How they help you: Ichneumonids target many vegetable- and fruit-crop pests. Commercially, they're used to control pests such as diamondback moths, European corn borers, and cabbage moths.

Special notes: In nature's systems, insects are not "good" or "bad," but simply living things that have a niche and a unique way of surviving. Ichneumonid wasps may parasitize the caterpillars of some of our favorite moths and butterflies, as well as spider egg sacs. However, these wasps target so many more of our problem insects that we clearly call them "beneficial."

TRICHOGRAMMA WASPS (*Trichogramma* spp.)

Distinctive features: These are very tiny, about the size of a pencil point. If you viewed a *Trichogramma* wasp through a microscope, you would see a squat, yellowish or brown wasp with red eyes and short antennae. Adults are about 1/50 inch long.

Fear of wasps is nearly paralyzing to some people. They avoid picnics, shun the porch, and invest in can after can of toxic sprays just to rid the house of a wasp nest. But most wasps are beneficial, although a few stings can make the friendliest human wary!

It may help you to know that none of the small parasitoid wasps described here sting people or pets at all. Even most large parasitoids like ichneumonid wasps are nonstinging. Their long ovipositors (egg-laying tubes) look threatening, but they're only a danger to insect pests. One species, the giant ichneumonon (*Megarhyssa macrurus*), can insert its ovipositor a full inch into wood and lay an egg on its victim (which is usually an insect larva in the tree).

If you find a nest of wasps near your house where you can't tolerate it, remember this: Wasps are most likely to be agitated and sting you if they're disturbed during hot, humid weather. Remove the wasp nest only on a cool, dry, dark evening, and place it where the wasps can escape unharmed.

Continued →

Hornets are a type of wasp, and believe it or not, some hornets are beneficial insects! Many people are afraid of hornets, but the European hornet is a predator that attacks grasshoppers, horseflies, and yellowjackets. Giant hornets and bald-faced hornets also destroy many insects. So leave hornets in peace as much as possible, both to avoid being stung and to allow them to carry out their beneficial duties.

Life cycle: Female wasps lay eggs in the eggs of another insect. The young pupate within the host egg, and one or several adults will emerge within a week. Several generations may develop each season. They overwinter as pupae in the host egg.

Where to find them: *Trichogramma* wasps are so small that you won't see them in your garden. However, they probably are there, frequenting plants with delicate flowers, such as Queen Anne's lace, tansy, coriander, and parsley. *Trichogramma* wasps are found throughout the United States.

How they help you: These wasps are one of the most widely used biological controls for commercial agriculture. They're released for control of imported cabbageworms, corn borers, corn earworms, cabbage loopers, and many other pests. They're effective only when released over a wide area, and the timing of the release has to be just right. In your home garden, rely on native *Trichogramma* wasps for pest duty.

Special notes: Biological controls like attracting or buying beneficial insects for pest control are rarely effective as single measures. (Instead, the smart gardener does several positive things at once—including arranging for many beneficials to be around at all times.) *Trichogramma* wasps are a good example: Since some of these wasp species emerge in warm weather, they're not very effective for early season pests, but growers can release them to help with pest problems later in the season.

BUTTERFLIES AND BEES

Attracting Butterflies and Moths

Sally Roth

I've never been a butterfly catcher, but I'm definitely a butterfly collector. One recent morning, I added three cloudless sulphurs, a red admiral, ten common blues, a red-spotted purple, and "the prize"—four gorgeous, great, spangled fritillaries—to my collection. Not to mention a dozen or so dainty white cabbage butterflies.

I do my "collecting" through the window at my desk, watching the butterflies that dance over the flowers outside. My new butterfly garden is in its first full summer and already it's a lively place. As more and more flowers come into bloom, the garden invites a visit from these colorful nectar-seekers.

Butterfly season can be as short as six weeks in the far North or in high mountains, but in mild southern Florida, butterflies fly all year. They begin to appear in numbers once the average daily temperature stays above 60°F, but in most areas, hot summer is when butterflies are at their peak. So a summer-blooming garden is a great way to attract butterflies to your natural landscape. An open, sunny spot is the best place to put a butterfly nectar garden.

You'll see the largest number of butterflies on warm, sunny days when the wind is calm or only a light breeze is blowing. When the sun clouds over, they disappear like magic.

Start with Flowers

Making a butterfly garden couldn't be easier. Flowers are the place to start. You'll want an abundance of them. Luckily, most of the best nectar plants—zinnias, for instance—are super-easy to grow and fast to bloom, and seeds and plants are available everywhere.

A new garden needs color in a hurry, so when I started my butterfly planting, I scattered seeds of fast-blooming annuals—old standbys like sweet alyssum, cosmos, and zinnias. Most of the packets I bought at ten-for-a-dollar seed racks, so I could use a liberal hand without counting pennies.

In the flower bed along the road, I sprinkled seeds I'd saved from an old garden. Of course, I hadn't labeled them. They turned out to be garden catchfly, or none-so-pretty, an old-fashioned wildflower that fell out of favor because of its hot-pink color, but which often turns up in butterfly or wildflower seed mixes. A neighbor from the farm down the road offered all the bachelor's-buttons I wanted: They'd snuck into her soybean fields. They transplanted nicely, making airy clumps of cornflower blue that bloomed for weeks. Any bare spots filled in fast with wild chamomile and white daisy fleabane.

The garden is a jumble of colors and plants, and the butterflies love it. This morning, cabbage whites and yellow sulphurs were dancing over the wild daisies. And the golden-brown spangled fritillaries, which get their name from a spangling of silver dots on the undersides of their wings, were feeding on the vivid pink catchfly.

Herbs for Nectar Collectors

Almost any plant that offers clusters of small, tubular flowers will be eagerly sought by butterflies. That description suits a lot of herbs: mints, rosemary, lavenders, and hyssops, just to name a few.

On the steep, stony hill beside our house, I planted lavender, thyme, and oregano, hoping they'd tumble down the slope in a pleasing mix of soft colors and textures. They did fill in well, and they brought a bonus: Their plentiful flowers are a super draw for butterflies.

The herbs are especially popular with little blue butterflies. I didn't realize how popular at first. When I glanced at the hill, I'd see a few small butterflies fluttering about, and I thought that was it. But then I discovered that when the blue butterflies fold their wings, their silvery undersides are perfectly camouflaged against the gray foliage. Only when they flutter to another flower or open their wings to bask for a moment do I get a glimpse of lovely lavender-blue like a summer sky.

Hosting Future Generations

Along with flowers and herbs, you'll want to make sure that your natural garden includes plenty of good host plants for butterflies to lay their eggs on. When future generations begin hatching in your garden, they'll tend to linger if there's plenty of nectar and host plants for subsequent broods. My own garden—and not only the "butterfly garden" part of it—sustains populations of spicebush swallowtails, black and tiger swallowtails, coppers, metalmarks, little blues, admirals, red-spotted purples, hackberry butterflies, and emperors. I like to look for caterpillars almost as much as I love to watch butterflies.

Butterflies are pickier than a four-year-old when it comes to food for their larvae. They look for very specific plants. Monarch caterpillars eat only milkweed. Most others are just as selective: Hackberries lay eggs on elm; spicebush swallowtails go for (what else?) spicebush; zebra swallowtails look for pawpaws.

Irresistible Oregano

If you grow herbs, you already know how attractive those tiny flowers are to butterflies. The myriad blooms on a single plant of oregano can keep butterflies busy for half an hour.

I grow oregano as an ornamental. One of my seed-started plants blooms with white flowers rather than the usual mauve flowers. It's a novelty in the garden that I enjoy for its own sake as well as for its nectar abilities. But any kind of oregano is tops with butterflies.

In two years, my single plant has spread into a tumbled mound that covers a good 3 square feet. I cut it back to the ground in winter, and it regrows with a vengeance, spreading by rooting branchlets. It begins to bloom in early summer and keeps going until frost. For months, it's a favorite stopping place for butterflies of all descriptions. The dainty hairstreaks find it particularly appealing, but big yellow tiger swallowtails and bold black-and-white zebra swallowtails also partake.

Having a patch of oregano is like having a living laboratory of insect life. More than butterflies visit my planting. I see wasps of all descriptions, from giant cicada killers to elegant, slim blue hornets. And a million other insects, give or take a few, are also drawn to the plant, providing me with hours of viewing pleasure.

When the eggs hatch, the first meal is right under their feet. Many caterpillars spend their entire lives on a single plant, never leaving unless the food runs out.

It's amazing how fast butterflies will find your garden if you offer suitable host plants. If you've ever grown broccoli, you've seen this in action. Those white butterflies flirting over your veggie garden are checking out a future home for their caterpillars.

An Eastern black swallowtail has a cloud of powdery blue and bright orange eyespots on its outer hind wing. Lure them to your garden with parsley, dill, Queen Anne's lace, or carrot plants for the caterpillars and nectar sources such as phlox and milkweed.

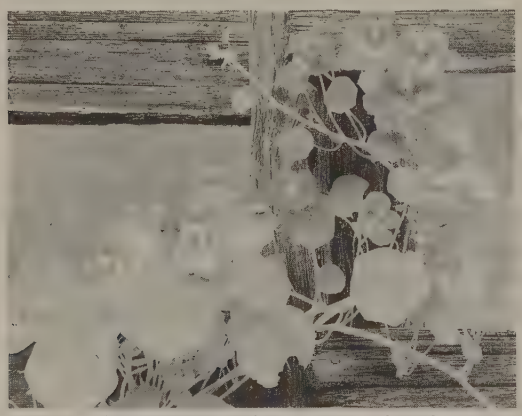
THE DANGERS OF PESTICIDES AND HERBICIDES

Pesticides and herbicides are the number one enemy of beautiful butterflies. Pesticides kill off adults and caterpillars. (Ever stop to think what that creepy green caterpillar on your roses might turn into?) And herbicides take care of future generations by destroying the "weeds" that butterflies lay their eggs on. Even the natural control *Bacillus thuringiensis* (BT) is deadly to butterflies and moths. It kills "leaf-eating caterpillars," and that includes just about every single one. Spray BT on your young oak to protect against gypsy moths, and you wipe out future lunas, cecropias, and everything else on the leaves, along with the pests.

Our American penchant for tidiness has eliminated too much prime butterfly habitat. Every highway roadside that's mown like lawn grass could be supporting hundreds of butterflies if it were left to grow naturally.



Nasturtium is a sprawler, not a true climber, but you can coax it along a fence or up a trellis to bring the bright flowers, and the butterflies that visit them, into easy view.

To be a friend of the butterflies, you'll have to overcome any neatnik urges in your own garden. The easiest way to boost butterfly numbers in your garden is to let a corner get a little weedy. You don't have to grow thistles—unless you want your neighbors to be really fond of you—but you can nurture clover, asters, sandvine, milkweeds, and seedling trees. Whatever crops up is likely to become home to one kind of butterfly larvae or another.

The Fine Art of Puddle-Making

If anybody ever saw me driving down the dirt road by our house, they might put in a call to the county sheriff: I weave from one side to the other like a drunken fool. It's not because I've been tippling, though. I'm trying to avoid the butterflies congregating at the mud puddles in the road. Yellow, white, and orange sulphurs; little blues; red-spotted purples; big, gorgeous swallowtails; and other beauties cluster around the edges of the puddles, drinking from the mud. Their delicate proboscis probes the mud, drawing up water and minerals like a portable drinking straw.

I use the same idea to draw butterflies to my garden. My installation methods are primitive: To create a mud puddle, I simply run the hose for about five minutes at about 11 A.M. each morning on a bare, somewhat gravelly patch of earth. For true puddle butterflies, it's not necessary to have standing water. Mud is what they're after.

If you make a mud puddle a feature of your garden, you'll attract more than butterflies. Chances are you'll also find toads if you look for them at night. They wait for earthworms to leave the saturated soil, then gulp them down. Usually a few gulps is all it takes to get a wriggler down the hatch, but once I saw a small toad using his "hands" to help shove the worm in. Robins will look for worms at your puddle, too, and they'll collect mud for nest-building. (By the way, if you see a robin with a balding breast, it has already built its nest: Smoothing out the cup of mud causes wear and tear on the feathers.)

Literate butterfly lovers appreciate the comma butterfly and its close relative, the question mark, which carry distinctive marks of punctuation on their outer hind wings. Look for commas in clearings, glades, and open woods.

Water in a Saucer

For the butterflies that prefer to drink water rather than mud, I fill a large, shallow, clay saucer with coarse gravel and pour in water. This stays wet all day, even in hot summer, and draws some of my favorite butterflies.

Usually the first to arrive are the fluttery brown-gold hackberry butterflies and the anglewings, mostly commas and question marks. Anglewings are a common type of butterfly that looks like a leaf when its wings are closed: Not only is the color right, but the edges of the folded wings are scalloped like the margin of a dead leaf. And question marks' closed wings boast punctuation marks that look like they've been painted on with Wite-Out. Like a bunch of impatient chickadees at the feeder, the golden-brown butterflies brush against my ankles as soon as I pull out the hose.

Red admirals stop by for a drink at the saucer, too. They're bigger butterflies, with dark brown wings slashed with a brilliant red stripe and a dash of white. Like the hackberry tribe, they're completely unafraid of me. They often ride on my shoulder or my hat while I work in the garden or walk to the mailbox.

Saved by the Computer

Black swallowtail caterpillars eat only plants in the carrot family, like dill, parsley, and Queen Anne's lace. I used to think that any particular black swallowtail caterpillar would eat all of those plants, but I learned differently when I found a group of five swallowtail caterpillars on my very last stalk of dill in the garden.

At the same time, I was also hosting a brood of swallowtails on parsley in the vegetable garden, and there was a third brood working on Queen Anne's lace near the driveway.

Wanting to raise a few butterflies, as I do every year, I took the dill stalk and its inhabitants indoors to a sunny windowsill. I filled their jar with fresh-picked parsley and waited for them to chow down. But they weren't interested. I tried Queen Anne's lace. Same deal. My caterpillars were hungry, but they wanted dill. Those caterpillars on the other plants must have come from different stock.

I made a quick trip to the supermarket and came back with a tiny $2 bunch of dill. When I put it in the jar, they fell upon it like wolves. They were hungry—much too hungry. That expensive dill wouldn't last long. I scoured friends' gardens and begged whatever dill I could find, but it was the end of summer and all I ended up with was a paltry bunch. Maybe it would hold them for the next week, I thought, and then they'll go into the chrysalis stage.

No luck. They ran through it in three days and were even bigger and more voracious. Every greengrocer for 40 miles around was out of dill. I was desperate. So I put out a message on CompuServe, the electronic communication service. The next morning, a fat package arrived by Federal Express, sent by an electronic friend. I could smell it as soon as I opened the door—fresh, fragrant dill! My caterpillars were saved. (And my very curious FedEx man felt like a hero.)

In two days, the caterpillars went into the chrysalis stage, transforming into elegant, pointed sarcophagii that hatched in another two weeks into fabulous, velvety black swallowtail butterflies. They clung to my fingertips as I carried them outside to release them, blissfully unaware of how close to oblivion they'd come.

I'm always delighted when a red-spotted purple shows up at my butterfly watering saucer. These elegant creatures seem like they should be rarities, but they're as common as starlings around here. Like most butterflies, the undersides of their wings aren't as pretty as the tops. In fact, they look like two different species altogether, depending on which side you're looking at. Underneath, they're drab brownish blue spotted with Chinese red, but seen from above, they're as gorgeous as the blue morpho butterflies of the Tropics. Their velvety, matte-black wings are overlaid with a sheen of cobalt blue and powdered with vivid turquoise along the edge.

More Than Nectar

Nectar isn't the only thing on the menu for butterflies. Some species have truly disgusting eating habits. Roadkill and other carrion are big favorites with hackberry butterflies, red-spotted purples, and admirals. Dead snakes are a particular delicacy, and in summer, I stir up clouds of butterflies every time I drive past a flattened opossum or raccoon. Though it seems incongruous to see butterflies eating carrion, it's just part of the natural foodchain.

Manure is manna for some butterflies, too, and the fresher, the better. They're quick to find any deposits left by our dogs, and I've also seen them sipping delicately at bird droppings. Some entomologists say that the manure of carnivorous animals is best. One butterfly collector in Africa turned to civet cats, the ordure of which he collected and placed at appropriate points in the forest paths. He was richly rewarded by obtaining many butterflies that he hadn't been able to get any other way.

Tree sap is another butterfly delight. When loggers toppled an old oak at our boundary line, the seeping trunk became a feeder for dozens of butterflies, including commas, question marks, hackberries, red-spotted purples, and monarchs. At night, when the beam of my headlights caught the stump, I saw dozens of teeny red eyes glowing in a perfect circle. When we walked up with flashlights, we found the stump was ringed with feeding moths, including many of the stunning underwings, whose usually concealed hind wings are striped vivid red or orange and black.

The monarch is the only butterfly that regularly migrates north and south as birds do. Hawk-watchers at mountaintop lookouts often see monarchs floating by along the same path as hawks and eagles.

Continued ➔

Fruit Feeders

One year, our little 'Seckel' pear tree bore a bumper crop, way too many for us to use, so I let some of the fruit hang on the tree. We noticed a few butterflies fluttering around the tree one afternoon and walked over for a closer look. It took me a minute to realize the tree was hosting scores of butterflies. They were clustered on the pears, their wings closed, and only the dull-colored, well-camouflaged undersides were showing. It was like one of those hidden-picture puzzles: "Can you find 50 butterflies in this picture?"

Most of the butterflies were my favorite red-spotted purples. The rest were mostly anglewings. Several kinds of anglewings roam my area, but the ones on the pear tree were commas and question marks. Though you can hardly see an anglewing when its wings are closed, the butterflies are glorious when they open, a flash of golden orange deepening into brown. The question mark, the bigger of the two species, sometimes shows a thin edging of lilac around its wings—a beautiful accent to its tawny color. Red admirals, hackberry butterflies, and tawny emperors made up the rest of the crowd.

I did a rough count of 40 butterflies on the 6-foot-tall tree, but it wasn't easy to get an exact number because some of them were pretty feisty. They'd shove each other off the fruit or battle in the air.

After a few minutes of watching, it occurred to me that the butterflies might be drunk. The most favored pears were also the most rotted, and I could clearly smell fermenting pear juice. Some of the butterflies were so besotted that they sat on my finger in order to keep drinking.

Raising Butterflies and Moths

This monarch caterpillar is ready to make the magic transformation from caterpillar to chrysalis. Monumental changes are going on inside that striped skin. When it splits, the chrysalis will be revealed.

Tending caterpillars through their metamorphosis into the adult form is one of the most rewarding nature studies I know. And to a kid, it's like magic. If you want easy results, stick with butterflies. A newly emerged butterfly is a creature of wonder. Fresh from its chrysalis, it pumps life into wrinkled wings, expanding them to perfect beauty. Every year, I try a new kind, as well as a couple of my standards—the monarchs and black swallowtails I've been raising since I was a child. These two are almost always a success.

It's easy and fun to raise your own butterflies from caterpillars. Just follow these simple steps.

1. When you spot a caterpillar feeding, put it into a clean, dry jar (18-ounce peanut butter jars fit on a windowsill nicely). Include a handful of whatever plant it was dining on and a bare stick that reaches from the bottom to near the top. Cover the jaw with a circle of cheesecloth held in place by a rubber band. Try to identify the caterpillar; if it's a moth, you may need to add soil to the jar.
2. Add fresh greenery every day, and remove the old stuff.
3. Every few days, carefully remove caterpillar, stick, and leaves, and dump out any droppings. Wipe out the jar with a damp paper towel, dry it, and then return the caterpillar, food, and perch.
4. Many butterfly caterpillars take about two to three weeks to go from hatching to chrysalis. Others may take a month or more, and some hibernate as caterpillars. They grow incredibly fast, shedding their skin as they get larger. If your caterpillar sits in one spot without eating or hangs from the stick, looking half-dead, don't despair; it's most likely getting ready to molt.

Be a Caterpillar Detective

Once you start looking for their calling cards, you'll find caterpillars all over your garden. Check your plants for any of these three telltale signs that say a caterpillar is at home.

- Chewed leaves. Look for holes and bare ribs in leaves. Or look for totally denuded stems. When I noticed that almost every leaf was missing from a bur marigold, I thought I was too late to catch the caterpillar. Then I noticed that one of the "twigs" was actually a brown-green pillar. He was clinging with his hind feet, his body sticking out from the stem at exactly the same angle as the rest of the bare branches.
- Frass, or caterpillar droppings. Watch for collections of tiny pellets, usually dark brown or black, on leaves or in leaf axils at a stem. When a new brood of question marks hatches in the oak tree over our driveway, I follow their growth by watching the frass on the roof of our white car: At first it looks like ground pepper, then coarse ground pepper, then peppercorns.
- Web shelters. Some caterpillars, such as the red-spotted purple, draw a leaf together with webbing to make a shelter. Be careful, though—spiders do the same thing. Don't poke your finger in and get caught unawares.

Once you find a caterpillar, it's fun to figure out just what it is. Check photos or drawings in field guides. You can narrow down the possibilities by identifying the host plant it's eating—many caterpillars have favorite food plants.

5. When your caterpillar is ready to pupate, it will anchor itself in a patch of silk, then hang. Many caterpillars loop a line of silk around their bodies to hold themselves at an angle from the support.
6. One day, probably when you aren't watching (caterpillars seem to have a knack for this), your lowly worm will transform itself into a magical chrysalis. Many chrysalises are camouflaged in drab browns; others are full of odd knobs. The monarch has the most beautiful chrysalis: It's a translucent green with gold dots that hangs like a Chinese lantern of jade.
7. Many chrysalises hatch in about two weeks; others may take months or may wait until next year. When your butterfly emerges, it will sit quietly in one place while its wings enlarge and harden. Carry it outside without jostling those fragile wings, and set it on a plant to take its first flight.

The chrysalis of the monarch butterfly is an ethereal, pale jade green, studded with gold. The plump chrysalis has a lid whose opening is marked with a delicate row of gold and black dots.

Host Plants for Moths

To boost the population of moth caterpillars in your garden, and thus the adult moths (which will come to the host plants for egg-laying), nurture the native plants of your region. Many of the most common shade trees are popular host plants for pretty, harmless moths. (Pest moths usually seek out the leaves of vegetables or food crops.) Trees like acacia, alders, apple, ashes, birches, cherries, elms, fringe-tree, hickories, honey locust, maples, oaks, pawpaw, plums, poplars, sweet gum, tulip tree, walnuts, and willows are favorites for moth caterpillars. They also like shrubs like ceanothus, sassafras, and spicebush, as well as perennial plants like milkweeds, mints, and plantains.

Regional Butterfly Checklist

Butterflies vary by region, just as birds and wildflowers do. The following species occur in all regions:

Orange sulphur
Coral hairstreak
Mourning cloak
Common sooty wing
Clouded sulphur
(yellow sulphur)
Gray hairstreak
Red admiral
Tawny-edged skipper
Common wood nymph
Painted lady
Checkered skipper
European cabbage white
Monarch
American painted lady
Spring azure
Viceroy
Silver-spotted skipper

In addition, you might see any of those listed below, depending on where you live. I like to keep an informal checklist each year. It's my own version of the Xerces Society's annual butterfly census, and it helps me gauge population changes and new visitors.

New England and the Mid-Atlantic

Zebra swallowtail
Giant swallowtail
Tiger swallowtail
Black swallowtail
Spicebush swallowtail

A Well-Meaning Death Trap

Commercially made butterfly feeders are big sellers, but I have yet to find one that I like. Last year I bought a yellow plastic contraption that was as poorly designed as it was ugly. It looked like a giant yellow daisy, as gaudy as a pink flamingo in the garden.

A plastic cover with grids for feeding spots covers the reservoir of sugar water. Butterflies liked the sugar water all right, and so did honeybees, yellowjackets, and bald-faced hornets. But the stinging insects weren't the real problem. The main reason I pitched the feeder was because it was a death trap.

The moat in the center is supposed to stop ants, but instead it trapped small butterflies, which managed to get in but couldn't climb out. Panicked, they battered their wings in the narrow space until they were broken wrecks. Every time I walked by the feeder, I had to free damaged butterflies or scoop dead ones out of the moat.

You can make a better, safe feeder yourself. Just put a piece of metal screening over a small saucer of sugar water. I set my sugar feeders on top of a post for easy viewing.

Can't Fail Concoctions

When I saw how butterflies, moths, and big, interesting beetles flocked to oozing sap on the bark of our very old, very decrepit oak tree, it gave me an idea. Why not try to replicate that sap and paint a tree with it?

Actually, the idea wasn't original. I vaguely remembered reading about such concoctions in one of the old turn-of-the-century butterfly books in my collection. The first old book I checked had a guaranteed-to-work recipe, but I wasn't sure where to locate one of the crucial ingredients: "one rank-smelling snake, dead four days or longer." Fortunately, the next book suggested a mixture of beer and sugar. I mixed it up, but it was so runny it wouldn't stick, maybe because I used granulated white sugar.

Finally I came up with my own recipes, which work like a charm:

1 bottle flat beer (open the bottle and let it sit the day before you make up the recipe)

2 boxes dark brown sugar

4 mashed bananas

or:

1 bottle molasses

½ cup cheap rum

1 cup water

I slosh the stuff together with a wooden spoon in a plastic bucket, then use a big paintbrush to apply it to tree trunks, fence rails, and an old stump along the paths in my woodland garden. Butterflies gather as soon as an hour after application, and at night, moths and beetles come to feast. I reapply the bait every day for about a week, then weekly after that.

Moths are more difficult to raise because most of them pupate in the soil. If I find a moth caterpillar, once I've figured out what kind of caterpillar I have, I supply a suitable habitat in an aquarium: a couple of inches of moist soil on the floor covered with a layer of dead leaves and debris. Some moth caterpillars refuse to pupate in captivity, at least for me. I've never had luck with the big pink-and-yellow imperial silk moths. Their giant hairy caterpillars are restless in captivity and won't go underground. Yet when I set them free, they seem to know they're outside and will walk a few inches, then burrow immediately.

Moths: Creatures of the Night

Have you ever wondered why some flowers are night-scented, saving their sweetest fragrance for the dark? Those flowers are sending a come-hither call to pollinating moths, which home in on the scent.

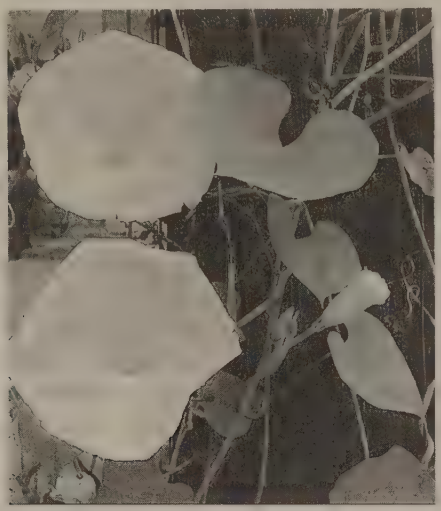
On languid summer evenings, when the smell of honeysuckle hangs in the heavy air, I often walk over to the hedgerow to watch the moths at work. Sometimes six or more sphinx moths will be feeding at the vine, setting the clusters of flowers quivering from the motion of their wings.

It may not warm your heart to learn that many of the moths that come to drink at the flowers in your night garden are Jekyll-and-Hyde characters: While they add grace to the night garden, their caterpillars (including tomato hornworms, tobacco hornworms, sweet potato hornworms, cutworms, and armyworms) can be detested garden pests. Not to worry, though: In the well-balanced state of a natural landscape, these caterpillars rarely reach threatening numbers. Birds, mice, shrews, and other predators will soon pick them off.

Moonflowers are another night delight. I wouldn't go a summer without them. I grow the vines in a wooden half-barrel on my deck, where they climb almost to the peak of the roof, aided by a tracery of strings. These big morning-glory relatives

Continued ➔

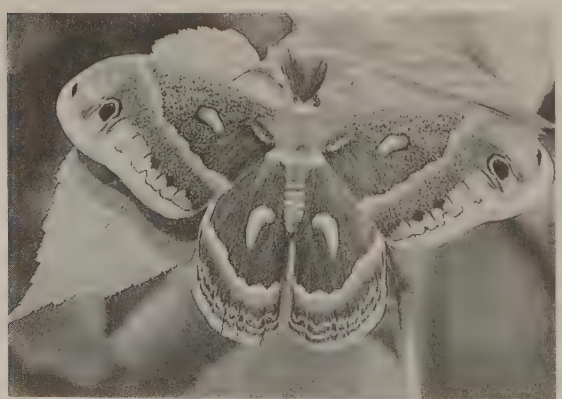
open at dusk, unfurling their petals while you watch. Like evening primroses (another night-garden plant that I wouldn't be without), the flowers release a delicious whiff of scent when they twirl open. Sit nearby, and it smells like you've been spritzed by the atomizer of a perfume bottle.



Pristine and perfect, the large blossoms of moonflower vine release a heady perfume when they unfurl at dusk. They self-sow, with restraint, even in cold-winter areas.

As soon as night-blooming flowers open, moths are there to greet them. Unlike butterflies, many moths extend their proboscis while flying to suck up nectar from the flower. That tomato hornworm you despise in your garden turns into a five-spotted hawkmoth, a dusky flier with a 4- to 5-inch wingspan and an extra-long sipping straw—its proboscis may extend 6 inches or more!

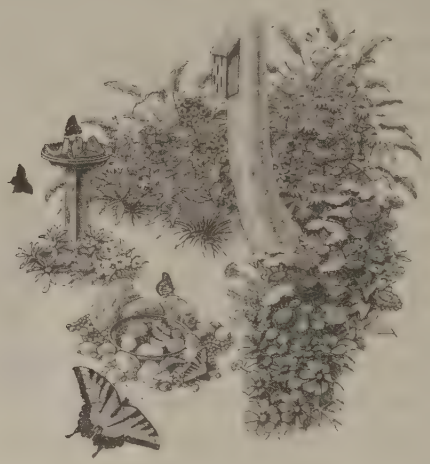
Odd as it seems to us, many moths lack functioning mouthparts. Once they have wings, these insects never eat. They live only for love, emerging from their cocoons for the sole purpose of propagating the species. Their lives may be as short as a few days; at most, they live a couple of weeks. Some of the most beautiful moths meet this fate. Among them are two groups of familiar moths:



Cecropia moths are as richly patterned as an antique paisley shawl. Look for the large red and white crescents on the hind wings. Wingspread can reach 7 inches.

Butterfly Shelter

Butterflies need the same basics as other wildlife—food, water, and shelter. Though it may take them a while to use the butterfly "house," they'll soon make use of a fruit feeding station and a water dish with wet sand or gravel and stones for safe landing. Other garden visitors will also be drawn to a butterfly feeding station, including wasps and hornets. There's no need to run scared, however: the thread-waisted insects will be so intent on their feeding that they usually don't mind a bit if you stand and watch. Just be sure to keep a respectful distance.



- Giant silk moths, which include the pink and brown cynthia moth, the Chinese-red and brown cecropia and Glover's moths, the rusty orange ceanothus and polyphemus moths, and the ethereal, celadon-green luna. Their wings can reach from 4 to 6 inches across.
- Tiger moths, including the dalmationlike leopard moth, the highly colored garden tiger and virgo tiger moths, and the clymene moth, whose wing markings form a fleur-de-lis when closed. The familiar brown and black woollybear caterpillar grows up to be a rather plain-Jane tiger moth, with golden-tan wings.

Moths give you a great reason to spend time in your garden at night, when you're home from work and can really enjoy it. Nectar-drinking types will visit your night-blooming or light-colored flowers, and others will seek mates and host plants in the hospitable habitats you've created. Just one glimpse of a luminous luna or a majestic cecropia will make you a moth gardener for life!

Bringing in the Beautiful Butterflies

Joan Benjamin and Deborah L. Martin

Want a garden that's colorful, healthy, and free of major pest problems? Just make sure that your yard is inviting to insect-eating birds, pest-destroying beneficial insects, and pollinating bees and butterflies.

The recipes in this chapter provide food for your invited guests. But butterflies and beneficial insects have some other needs too—specifically, water, shelter, and living space. These essential items are easy to provide, and because water and sheltering plants are attractive, you'll enjoy them as much as the beneficials.

Start with water. Butterflies and beneficial insects can't survive or thrive without it. Mud puddles and a shallow pan of water that's filled with small stones will give butterflies and beneficial insects a place to land and drink. Change the water in containers frequently—daily if possible—so that butterflies and beneficial insects can always get a fresh, clean drink.

A Fluttery Butterfly Garden

Butterflies can't live on nectar alone. If you want to attract lots of butterflies and get them to stick around, try this three-part recipe from LuAnn Craighton, a naturalist with the education department at Callaway Gardens in Pine Mountain, Georgia. LuAnn says the first step is to pick a place with the right living conditions. Next, grow a variety of plants. And third, care for the plants organically.

Ingredients and Supplies

10 nectar-producing flowers for adult butterflies

10 host plants for butterfly caterpillars

1 (or more) 3 x 3-foot sunny garden spots sheltered from strong winds

1 or 2 flat stones (for warming spots)

Shallow puddle or terra-cotta saucer filled with wet sand and laced with a few dashes of Epsom salts

1 seat (for butterfly watching)

Directions

1. In a spot that gets at least 6 hours of sun each day, plant a variety of plants that attract butterflies and provide food for their young.
2. Add 1 or 2 flat stones where the butterflies can warm themselves.
3. Provide a puddle or other shallow water source so that your butterflies can drink or search for salts.
4. Site a bench where you can enjoy the show!

FLUTTERY FACTS

- Butterflies are cold-blooded and don't get moving until their body temperature reaches about 80°F.
- When butterflies gather in groups around puddles, they're after salts in the mud, not just the water.
- Larvae chew holes in the leaves of host plants, but seldom harm the plant.
- The organic caterpillar killer BT (*Bacillus thuringiensis*) controls cabbage loopers and other vegetable-eating larvae. But it will also kill butterfly larvae if it drifts to their host plants. Avoid BT and hand-pick problem caterpillars, or be *extremely* careful if you use BT.
- In hot, dry climates, butterflies appreciate dappled shade in the heat of the day.

A Bee-ootiful Garden

Be a friend to bees by growing plants that will attract them to your garden. A mixture of perennial herbs and self-sowing annuals attracts bees and adds beauty to your garden too, says Rose Marie Nichols McGee, president of Nichols Garden Nursery in Albany, Oregon. The plants in this mix are so easy to grow that "it's hard to go really wrong with it," she adds.

Ingredients and Supplies

1 seed packet sweet alyssum

1 seed packet catmint (or buy small transplants)

1 seed packet coriander

1 seed packet dill

1 seed packet tansy phacelia

1 seed packet poached egg flower or meadow foam

1 seed packet corn poppies

1 seed packet single-flowered sunflowers

1 seed packet white yarrow (or buy small transplants)

Organic fertilizer (optional)

Directions

1. In early spring, prepare planting areas on the borders of your garden. A band of flowers 1 foot wide will bring bees and all kinds of other beneficial insects. Depending on the amount of seed per packet, this mix covers between 100 and 200 feet of border.
2. Sow small amounts of each type of seed on prepared ground that's moderately fertile and free of weeds. (In areas with mild winters, you can plant seed in the fall if you prefer.)
3. Gently water the seeds in and keep the ground evenly moist while the flowers are getting established (the first month or so after planting).

Moonlight Garden Design

Enjoy your garden in a whole new light by planting light-colored and white flowers that show up prettily at night. Delight all your senses by including flowers with fabulous evening fragrance, too.

If you like to entertain without a lot of fuss, a moonlight garden is the perfect place for a party on a balmy summer's eve. Your guests can have the fun of watching night-bloomers like the moonflower vine open their flowers, and no one will ever notice if you've been less than perfect about weeding.

Watch for night visitors in your moonlight garden. Bats may swoop down to scoop up insects at flowers, and big sphinx moths will hum at blossoms like night-flying hummingbirds.

Plant List

1. Honeysuckle (*Lonicera japonica* or *L. fragrantissima*)
2. Sweet alyssum (*Lobularia maritima*)
3. Pale evening primrose (*Oenothera pallida*)
4. Night-scented stock (*Matthiola bicornis*)
5. Petunias (*Petunia integrifolia*)
6. Tobacco (*Nicotiana rupestris*)
7. Lemon lilies (*Hemerocallis flava*)
8. Moonflower vine (*Ipomoea alba*)
9. Yucca (*Yucca filamentosa*)
10. Evening primrose (*Oenothera biennis* and other spp.)
11. Madonna lilies (*Lilium candidum*)
12. White-flowered Japanese wisteria (*Wisteria floribunda*)
13. Formosa lilies (*Lilium formosanum*)
14. 'Ida Miles' daylilies (*Hemerocallis* 'Ida Miles')
15. 'Eenie Weenie' daylilies (*Hemerocallis* 'Eenie Weenie')
16. Moonflower (*Datura inoxia* spp. *inoxia*, also sold as *D. meteloides*)
17. Flowering tobacco (*Nicotiana sylvestris*)
18. 'Mt. Fuji' phlox or other white cultivars (*Phlox paniculata* 'Mt. Fuji')
19. Flowering tobacco (*Nicotiana alata*)
20. Night phlox (*Zaluzianskya capensis*)
21. Four-o'clock (*Mirabilis jalapa*)
22. Night-blooming cereus (*Selenicereus*, *Hylocereus*, *Peniocereus*, and other genera)

4. Once the seeds are up, water them with a diluted organic fertilizer, such as a weak solution of fish emulsion or liquid seaweed. If your soil is good and fertile, you can skip the additional fertilizer.

Fruit Feeder Attracts Butterflies

Ripened fruit attracts many species of butterflies, says David Roth-Mark of New Harmony, Indiana. He offers butterflies all kinds of fruit buffets, and has discovered that they seem to like pears and bananas the best, "especially when the fruit is really soft and brown."

David surmises that the butterflies are more easily able to pierce the flesh of the fruit with their proboscis when it's overripe. He peels the bananas and slices the pears in half lengthwise before putting them on his feeder. "One pear can last for a week," he says, "so it doesn't cost much to keep them happy."

Watermelon Magnet for Monarchs

Watermelon on the patio is a regular part of summer life—a slice of summer that butterflies, especially monarchs, enjoy, too, says nature lover Pauline Hoehn Gerard of Henderson, Kentucky. "I keep a chunk of watermelon on the deck rail just for butterflies," says Pauline. "In late summer, there might be a dozen butterflies eating at the same time." She adds that the butterflies seem to enjoy the watermelon most when it's overripe.

Butterfly Nectar Garden Design

A wealth of nectar plants is an invitation that's impossible for butterflies to decline. They'll flock to your garden for the sweet nectar in this long-blooming garden, which offers food all season but hits its peak in summer, just when butterflies are most numerous.

Many of the plants in this garden will also attract egg-laying butterflies, boosting your butterfly population by doing double duty. Asters, for instance, will attract pearl crescents; butterfly weed may host monarchs; and turtlehead may draw Baltimore checkerspots.

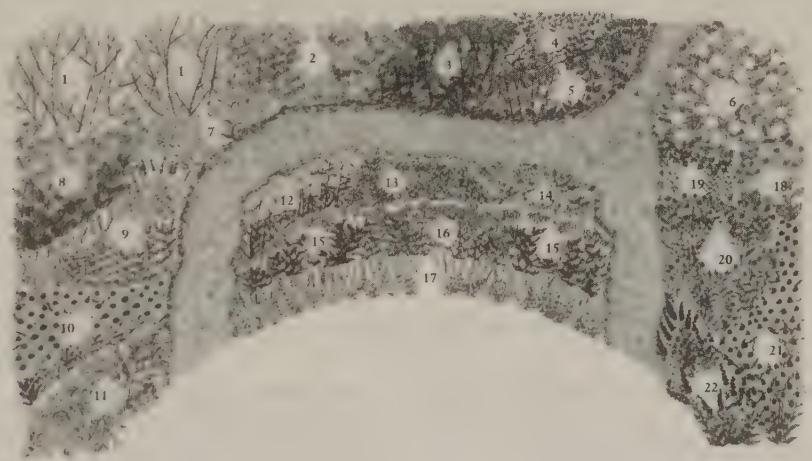
It's fun to keep a logbook noting which butterflies visit, how many, and when. Butterflies have their season, just like flowers do. Spring brings little blues; summer, the swallowtails; and monarchs peak late in the season.

By keeping track of who's who, you can learn the butterflies as they appear, and you will build a record of butterfly populations in your garden. You may want to jot down notes on the weather, too, so you can compare your log year by year: Does a rainy spring mean more or fewer butterflies in the garden? Does an extra-cold winter foretell a shortage of butterflies next spring?

A butterfly garden is simply full of pleasures and possibilities.

Plant List

1. Spicebush (*Lindera benzoin*)
2. Common milkweed (*Asclepias syriaca*)
3. Joe-Pye weed (*Eupatorium maculatum*)
4. Ironweed (*Vernonia noveboracensis*)
5. Mexican sunflower (*Tithonia rotundifolia*)
6. Seckel pear tree (*Pyrus communis* 'Seckel')
7. Azure aster (*Aster azureus*)
8. False sunflower (*Heliopsis helianthoides*)
9. Pink turtlehead (*Chelone lyonii*)
10. Small black-eyed Susan (*Rudbeckia triloba*)
11. Oregano (*Origanum vulgare*)
12. Swamp (pink) milkweed (*Asclepias incarnata*)
13. Purple New England aster (*Aster novae-angliae*)
14. Garden phlox (*Phlox paniculata*)
15. Mistflower (*Eupatorium coelestinum*)
16. Butterfly weed (*Asclepias tuberosa*)
17. Catmint (*Nepeta mussini*)
18. Sawtooth sunflowers (*Helianthus grosseserratus*)
19. Heart-leaved aster (*Aster cordifolius*)
20. Purple coneflower (*Echinacea purpurea*)
21. 'Goldsturm' black-eyed Susans (*Rudbeckia fulgida* var. *sullivantii* 'Goldsturm')
22. Butterfly bush (*Buddleia davidii*)



Continued ➔

Swallowtails Think Purple

Many backyard butterfly enthusiasts have noticed that big swallowtails seem to prefer the color purple, and Jim Becker, co-owner of Goodwin Creek Gardens, agrees. "It seems that purple and swallowtails go together," he says. "Brazilian vervain (*Verbena bonariensis*) is absolutely excellent for attracting butterflies."

This tall, bare-stemmed perennial offers its clusters of tiny, short purple flowers for months, until frosts stop it for the season. It's easy to plant anywhere in the garden, but be sure to keep some near the front of the bed, where you can watch the butterflies that come to visit. Jim also recommends another

Moth or Butterfly?

Almost all moths fly at night, but that's not a surefire way to tell the two apart. Some moths fly during the day, and others are crepuscular, coming out in late afternoon or early evening.

If you're in doubt, check the antennae. Butterflies have "clubbed" antennae, with visible thickening at the tips. The antennae are thin, and if you look very closely, you'll see they're segmented.

Moth antennae lack the club at the tip, tapering to a point instead. Their antennae are often feathery, sometimes extravagantly so. And moth bodies are plumper and furrier than those of butterflies.

Fruit Plate for Butterflies

If you don't have a pear tree in your garden, you can set up a mini-version with a couple of ripe pears from your supermarket. Here's how:

1. Nail a plastic dinner plate (check a thrift shop for one in an unobtrusive color) to the top of a post. I like to keep my butterfly feeder at waist level, where it's easy to watch.
2. Let two or three pears ripen until they're very soft, then slice them in half and set them on the feeder. Overripe watermelon is also a big draw, especially for monarchs.
3. It may take a few days for the butterflies to discover the fruit, but they will come. So will wasps, so keep the feeder out of the line of traffic to avoid mishaps.
4. You'll see that the fruit remains attractive—to the butterflies, that is!—even when it's unappealing brown mush. In fact, that's when it's most attractive to them. Butterflies eat by sucking up liquids through their proboscis (say "pro-BOSS-iss"), and the more rotted a fruit is, the easier it is for them to feed on it. Lean close and you can watch a butterfly unroll its coiled proboscis and insert it like a straw.

Best Shrubs for Butterflies

Shrubs	Description	Conditions	Comments
Blue spirea (*Caryopteris* spp.)	Open, small-foliaged, gray-leaved, woody perennial or shrub with filmy clusters of light to medium blue or blue-purple flowers in late summer. Grows 3–5′ tall and 3′ wide.	Full sun. Loose soil with excellent drainage. Most species, Zones 5 to 9.	Late-blooming flowers are highly attractive to butterflies.
Butterfly bushes (*Buddleia* spp.)	Deciduous or semievergreen shrub to 10′ or more with conical spires of flowers at each branch tip in summer. Grows 4–5′ wide.	Full sun. Ordinary soil. Zones 5 to 9, depending on the species.	Flowers are sweetly fragrant. Many cultivars are available.
Ceanothus (*Ceanothus* spp.)	Deciduous or evergreen shrubs with dense form and abundant clusters of tiny, usually blue or blue-purple flowers in spring and summer. Grows 1–6′ tall or more; width varies.	Full sun. Average to dry soil. Most are hardy only to Zone 8, except for white-flowered New Jersey tea (*C. americanus*) and western snowbrush (*C. velutinus*), which are hardy to Zone 4. Most thrive to Zone 10 (maximum).	Blooms last for weeks.
Privets (*Ligustrum* spp.)	Deciduous or evergreen shrubs or small trees with small leaves and highly scented, small, white flowers in summer. Grows 3–15′ and 4′ wide.	Full to partial sun. Average to poor soils. Hardiness depends on species; common privet (*L. vulgare*) is hardy to Zone 4. Other species, Zones 5 to 7.	An old-fashioned standard that's not often used in today's gardens. Privet is unbeatable as a dense, fast-growing hedge. The fragrant flowers attract many butterflies.

verbena, a sprawling hybrid called 'Homestead Purple' that grows so fast you can use it as a groundcover.

Nature Versus Nurture

Sometimes Mother Nature's haphazard plantings teach the most useful lessons about gardening. "I planted all the flowers the books said in order to attract butterflies," says Pauline Hoehn Gerard, "but I still didn't have many." Then she remembered how many butterflies she saw fluttering over the milkweed (*Asclepias* spp.), ironweed (*Vernonia noveboracensis*), and asters along the dirt lane to her house when she was a girl. She brought home some of these "weeds" from her mother's land, and she quickly found that butterfly visitations increased dramatically. It turns out that Pauline's old "weed" favorites are all-American natives that bloom from the middle of summer on, when butterfly populations are at their peak.

Pick the Right Nectar Plants

You don't have to resort to trial-and-error to find out which plants attract butterflies. Ann Swengel, a vice president of the North American Butterfly Association (NABA), suggests growing some of these nectar and host plants as a starting point for attracting a variety of butterflies. For a much longer list, write to NABA at 4 Delaware Road, Morristown, NJ 07960.

Plant	Description	Hardiness Zones
Black-eyed Susan (*Rudbeckia hirta*)	Yellow and brown daisylike blooms; 2- to 3-foot-tall hairy-leaved plant	Annual
Purple coneflower (*Echinacea purpurea*)	Rose-pink daisylike blooms; 2- to 4-foot-tall perennial	Zones 3 to 8
Yellow cosmos (*Cosmos sulphureus*)	Yellow, orange, or red daisylike blooms; 2- to 3-foot-tall bushy plants	Annual
Goldenrods (*Solidago* spp.)	Plumelike clusters of golden or yellow blooms; 1- to 5-foot-tall perennial	Zones 3 to 9
Impatiens (*Impatiens walleriana*)	Flat, spurred blooms in lavender, pink, red, orange, or white; 6- to 24-inch-tall, neatly mounded plants	Annual
Joe-Pye weeds (*Eupatorium* spp.)	Substantial clusters of fuzzy rose-purple flowers; bold 3- to 12-foot-tall perennials	Zones 3 to 8
Lantanas (*Lantana* spp.)	Flat-topped clusters of red and yellow or pink blooms; 18-inch- to 4-foot-tall shrubby plant	Zones 8 to 10 (treat as an annual farther north)
Lupines (*Lupinus* spp.)	Dense 2-foot-long spikes of pealike flowers in shades of pink, white, blue, purple; bushy perennials grow 2½ to 3½ feet tall	Zones 3 to 6
French marigold (*Tagetes patula*)	Daisylike to rounded red and yellow blooms (choose single-flowered cultivars instead of doubles—butterflies can reach the nectar more easily); 6- to 20-inch-tall plant with strongly scented leaves	Annual
Mints (*Mentha* spp.)	Spikes of small, 2-lipped purple, pink, or white flowers bloom at top of plants; bushy, spreading perennials grow to 2 feet tall	Zones 5 to 9
Pineapple sage (*Salvia elegans*)	Small bright-red 2-lipped blooms; 2- to 3-foot-tall herb with fragrant leaves	Annual
Rose verbena (*Verbena canadensis*)	Rounded clusters of purple, rose, or white blooms; 8- to 18-inch-tall perennial	Zones 4 to 10 (treat as an annual farther north)
Brazilian vervain (*Verbena bonariensis*)	Rounded clusters of tiny violet blooms; 3- to 4-foot-tall perennial	Zones 7 to 9
Zinnia (*Zinnia elegans*)	Round, flat, or mounded blooms in every color but blue; 6- to 36-inch-tall plants grow low and mounded or upright and bushy	Annual
Glossy abelia (*Abelia x grandiflora*)	Clusters of small pinkish purple or white blooms; 3 to 6 feet tall and wide; rounded, semi-evergreen shrub	Zones 6 to 10
Azaleas (*Rhododendron* spp.)	Lavender, orange, pink, red, white, or yellow funnel-shaped blooms; 1 to 20 feet tall (depending on species); evergreen and deciduous shrubs	Zones 4 to 9
Orange-eye butterfly bush (*Buddleia davidii*)	Pink, purple, red, or white fragrant lilaclike blooms; 5- to 15-foot-tall arching plant that flowers best if cut back to the ground each spring	Zones 5 to 10
Lilacs (*Syringa* spp.)	Large, very fragrant blue, lavender, pink, or white bloom clusters; 4- to 20-foot-tall upright plants look loosely rounded over time	Zones 3 to 7

Best Vines for Butterflies

Vines	Descriptions	Conditions	Comments
Honeysuckles (*Lonicera* spp.)	Various species of evergreen or deciduous vines, some highly invasive, with red, yellow, white, pink, coral, or bicolor tubular flowers, usually fragrant and rich with nectar. Bloom summer through fall.	Sun to partial shade. Most soils. Most species. Zones 4 to 9.	Try coral honeysuckle *(L. sempervirens)*, a beautiful, red-flowered species that attracts hummingbirds as well as nectar-seeking butterflies.
Honeyvine (*Cynanchum leave*)	Long, heart-shaped leaves and rounded clusters of extremely fragrant, small, creamy white flowers on a deciduous vine. Blooms in summer.	Full sun to partial shade. Widely adaptable. Zones 6 to 9.	This milkweed relative smells as sweet as honey and attracts nectar-seeking butterflies as well as egg-laying monarchs. Self-sows freely and can become pesty if you don't keep after seedlings.
Passionflowers (*Passiflora* spp.)	Intricate flowers of mythic religious symbolism dot these deciduous vines, followed by showy, often edible fruits. Blooms in summer.	Full sun to shade. Ordinary soil. Many are tropical, maypop *(P. incarnata)* is hardy to at least Zone 6. Most species, Zones 6 to 9.	In southern states, the Gulf fritillary lays eggs on the leaves of passionflower vines.

Barbara Trick, office manager for Aullwood Audubon Center and Farm, uses native trees to attract butterflies. Tulip trees, hackberries, maples, oaks, and white ash are nurseries for swallowtails, giant silk moths, and other winged beauties.

"Beefsteak" for Butterflies

When her Beefsteak tomato crop swelled and cracked one year in the heat, Deborah Burdick, of Mt. Vernon, Indiana, discovered that the cracked, leaking fruits turned out to be butterfly attractors. "I was walking out for my mail when I saw motion at the tomato plants. There were a bunch of butterflies—beautiful golden ones that I learned were hackberry butterflies, and some beautiful black and blue red-spotted purples! Now I leave some of my cracked tomatoes on the vine just for the butterflies."

All Around the Butterfly Bush

The single butterfly bush (*Buddleia davidii*) in the back of Janice Ostock's garden in Bethlehem, Pennsylvania, drew a steady stream of butterflies, but it was hard to get a glimpse of the butterfly visitors close up. So she created her own butterfly visitors' center by adding a path that circled the bush. The butterflies often retreat to the back of the bush when an observer comes near, says Janice, but the new walkway puts the nectar sippers in full view.

Early Bloomers for Early Butterflies

When a few days of unseasonably warm weather late in winter coax early butterflies from their sheltered niches beneath bark, not many flowers are waiting to greet them. Nature lover Pauline Hoehn Gerard felt sorry for the early butterflies because there was no nectar to sip, so she planted early-blooming autumn-flowering cherry (*Prunus subhirtella* 'Autumnalis'), which she notes blooms not only in fall but also in late winter, whenever the weather turns mild for just two or three days.

Pauline also recommends winter-flowering witch hazel (*Hamamelis x intermedia* 'Arnold Promise'), whose ribbony-petaled flowers offer sustenance until real spring arrives. Pussy willow is another great food source for butterflies. When early butterflies such as the tiny blue spring azures and the elegant, understated mourning cloaks emerge from winter slumber, there's a banquet of rich nectar waiting for them.

Butterflies Think Lavender Is Lovely

Barbara Trick, office manager for Aullwood Audubon Center and Farm in Ohio, loves her patch of lavender. When the sweet blue-purple flowers bloom, "it's absolutely covered with butterflies and bumblebees," she says. "There are so many honeybees and bumblebees at it that the plants practically vibrate." Jim Becker, co-owner of Goodwin Creek Gardens in Oregon, concurs with Barbara about lavender. "Lavender has proven to be an excellent butterfly flower for us," he says, noting that his visitors include masses of skippers and western swallowtails.

Spritz the Bricks for Butterflies

As David Roth-Mark of New Harmony, Indiana, was watering the potted plants on the family deck one July, he noticed that butterflies were attracted to the wet spots on the bricks. So a couple of times a day, he wets down the bricks with the hose to give butterflies a drink. Many butterflies are puddle-sippers and seek out hospitable wet spots to congregate and drink. If you don't have bricks to wet with the hose, you can keep a spot of gravel wet or make a butterfly drinking station out of an old cookie sheet or big clay saucer lined with gravel or river stones.

But there still may be a missing piece needed to turn your yard into a good butterfly habitat: plants that larval butterflies (caterpillars) like to eat. Most caterpillars grow up on a diet of wild tree, shrub, or weed leaves, but a few prefer herbs and other

garden plants. Plant a few extra carrot family herbs, and you can watch the drama as tiny green-and-black-striped caterpillars gain size daily, and eventually become black swallowtail butterflies.

The small, fragrant flowers of many herbs also attract wild and domestic bees, which provide their pollination services free of charge. Also expect to see a huge range of beneficial buzzers that help keep peskier insects under control.

Chives (*Allium schoenoprasum*)

Garlic chives (*Allium tuberosum*)

Dill (*Anethum graveolens*)

Lavender (*Lavandula* spp.)

Oregano (*Origanum* spp.)

Parsley (*Petroselinum crispum*)

Rosemary (*Rosmarinus* spp.)

Pineapple sage (*Salvia elegans*)

Creeping thyme (*Thymus serpyllum*)

Vicki Mattern

The best garden aid you could ever invest in is probably sitting outside your window right now, ready to work for peanuts—or sunflower seeds. See that chickadee out there—the one with the bright black eyes and friendly cocked head? No doubt he's one of your feeder favorites. Now take a look at those starlings lurking nearby, ready to drop down by the dozen, scaring off your small feeder guests. You've probably wondered what you could do to discourage them. Big mistake. Every bird in your yard is valuable, especially in winter. That's when future populations of pests get stopped dead—literally—by the sharp eyes and quick beaks of the feathered army.

No Such Thing as Eating Like a Bird

Watch a bird when it leaves your feeder and you'll see that it constantly is searching out bits of food from every part of your garden. Finches sway on the stems of lamb's-quarter and ragweed, devouring seeds that would otherwise sprout in your beds. Sparrows, juncos, and towhees scratch beneath plants, vacuuming up fallen seeds and any insects that cross their path. Even the common house sparrow helps out, eating thousands of seeds of crabgrass, chickweed, purslane, and other weeds. Chickadees tear open cocoons of bagworms and other pests, munching the tasty morsels inside.

Nuthatches scour trees top to bottom in a comical upside-down posture that gives them a great vantage point for picking insects and their eggs out of cracks in the bark. The brown creeper covers niches that nuthatches overlook, spiraling from bottom to top of the same trees. Woodpeckers whack their way into tree bark and plant stems, ferreting out hidden larvae and harmful ants and beetles. Even those scorned starlings earn their stripes, patrolling your lawn with sharp, stabbing beaks for Japanese beetle grubs.

Consider that a single chickadee—maybe the very one who's entertaining you outside the window right now—can down a thousand or more scale insects, aphids, codling moths, pear psyllas, pine weevils, and other delicacies in just one day, and you get some idea of the immensely positive potential of a bird's appetite. That's why it makes such great gardening sense to invite more birds to your yard. Fewer pests mean healthier flower gardens, bigger and better vegetables, long-lived trees and shrubs, and less work for you.

In a single day, one diminutive house wren can consume 500 beetles, grubs, and insect eggs. More than half of a chickadee's winter diet is aphid eggs. And a swallow can consume incredible numbers of flying insects—by one researcher's count, a single swallow ate more than 1,000 leafhoppers in less than a day.

A Delectable Landscape

Unless your property is barren of trees, shrubs, and flowers, you'll be delighted with bird visitors who regularly stop by to check out your offerings. But you can attract far more birds by offering a few bird amenities, such as berry-producing shrubs and fruit trees, water for drinking and bathing, and nesting spots in trees and birdhouses. Your first visitors will undoubtedly be robins, nuthatches, hummingbirds, titmice, cardinals, and sparrows, but with a little extra enticement, you can welcome special birds, such as bluebirds, goldfinches, and juncos.

Feeders, birdbaths, and birdhouses play a vital part in bringing birds to your backyard garden. But trees, shrubs, and flowering plants can fill the same role without extra effort from you! Plants provide food, cover, and nesting sites, and because they trap dew and rain and control runoff, they help provide water, too.

When choosing plants, look for food-bearing species that will provide fruits, buds, and seeds throughout the year. Mix deciduous and evergreen varieties in order to provide cover and shelter all year round. Native species are usually the biggest bird attractant, and local birds will turn to them first for food and cover.

Doing Your Part

In winter, a feeding station is the best way to lure the anti-pest squad to your yard. It takes a lot of fuel to keep those hyperactive bodies humming, so easy pickings are always welcome. But don't worry about your feeder birds getting lazy. Maybe bugs and weed seeds taste better than birdseed, or maybe it's just in the genes, but birds will still glean your garden no matter how delicious a banquet you spread.

For results right now, all you need are a few dollars' worth of seed, a simple cylindrical or open tray feeder, and a plastic mesh onion bag stuffed with suet (or freebie beef trimmings). If you like, add a source of water or a discarded Christmas tree for shelter to make your yard an even better place for birds to linger. Within a week or two, you'll have a host of garden helpers for pest control at its finest. You'll also enjoy the pleasure of their company. When your garden is alive with birds, even the grayest winter day can be a delight.

Holiday Feast

Winter birds love a Christmas feast even after the holiday. Set your Christmas tree outside where it's sheltered from the wind, then gather leftovers from holiday baking to make garlands of raisins, nuts, and dried fruit slices. For "ornaments," fill citrus rinds with peanut butter and fruit.

Winter Berries for the Birds

Vicki Mattern

Bird watching can be habit forming. The chair by the bird feeder window is often the most popular seat in the house. But not all birds live on feeder meals alone. Some simply will not eat from a feeder, no matter how tempting the treats are. To attract the largest variety of birds into your backyard in the cold months, you must also plant the right shrubs, bushes, and trees for them.

The best bets are those plants that produce plenty of berries and hold them on their branches into winter, when other food sources become sparse. These plantings can provide not only food but also shelter for your wild, feathered visitors all year long. Additionally, many of these bushes can serve as foundation plantings and bring birds close to your viewing window.

Birds are gluttons when it comes to berries: They can't eat just one. Flocks of robins or tanagers will return day after day until every berry on your dogwood is history. And once the berries are gone, so are the birds.

You can extend the season by planting different cultivars and types of berries. A combination planting of shining sumac, elderberry, and winterberry holly, for example, will ensure a steady level of bird activity around your yard.

Going Native

When choosing trees and shrubs for the birds, always try to use native varieties no matter where you plant. Natives will thrive naturally in your soil and climate. And you rarely need to fuss with soil improvements, fertilizer, or extra watering.

Also, research shows that foraging birds seek out the familiar over the exotic species. Putting native plants into your garden and yard will give you an edge in attracting birds. So instead of planting a hedge of forsythia, which has little bird value, try a food-providing hedge of bayberry, blueberry, elderberry, or sumac. It can work as a border planting or hedgerow, and will supply tasty morsels for many birds.

Birds don't care how good your landscape design skills are, but a yard with bird appeal should also look good to your eyes. Whether you like straight edges, right angles, and controlled plantings of a formal style, or the casual plantings and curving lines of an informal or naturalistic garden, you can take steps to build bird appeal. Remember that birds are more likely to take up residence in an area that has little traffic. If you can keep at least part of your yard undisturbed, or nearly so, with low-maintenance or naturalistic plantings, birds will soon build nests in the hedges, shrubs, and trees.

There are many attractive berry bushes for the birds, but here are four genera—dogwood, holly, sumac, and viburnum—whose varieties and cultivars are adaptable to a wide range of soil conditions and climates.

Dogwoods

Dogwoods (*Cornus* spp.) are always a big hit with fall- and winter-feeding birds. Many of these birds are accustomed to seeking out dogwoods because so many of the native species bear fruit. Bluebirds, grosbeaks, tanagers, thrushes, vireos, waxwings, woodpeckers, and a host of other birds adore the dogwoods' red, shiny berries.

Most of the North American varieties are shrubs with casual growth habits. Flowering dogwood (*Cornus florida*) is a superb small tree for a partly shaded site to Zone 5. Other, lesser-known dogwoods are just as popular with birds, although they seem to be a well-kept secret among gardeners. Many species are available, including pale, or silky, dogwood (*C. obliqua*) and red osier dogwood (*C. sericea*), two shrubs that make fine windbreaks or cover habitat at feeding stations; they bear clusters of stemmed fruits that are eagerly stripped by birds. The native gray dogwood (*C. racemosa*) has attractive blue-green foliage, white flowers, and whitish berries, and it makes an excellent shrub for either a landscape border or naturalized area.

Native dogwoods may be sold at extremely reasonable prices by your state department of natural resources or through county extension offices. You also can check with a nearby nature center or native-plant specialist to get recommendations for your region.

Include These Vines in Your Wildlife Garden

Vines make a perfect centerpiece for a garden designed to attract birds, butterflies, and other wildlife. Hummingbirds are drawn to colorful blooming vines with tubular flowers, such as cypress vine (*Ipomoea quamoclit*), trumpet honeysuckle (*Lonicera sempervirens*), and orange trumpet vine (*Campsis radicans*). Butterflies are attracted to cypress vine and sweet peas (*Lathyrus latifolius*).

Hollies

When holly berries are ripe, every day is Christmas for the birds. Many varieties of birds will come and visit continuously until all the berries are gone. The berry-laden branches of the deciduous variety 'Winter Red' can be stripped bare in just minutes! Hollies attract at least 12 species that eat its berries, including cedar waxwings, eastern bluebirds, and northern mockingbirds.

Most of us think "evergreen" when we think of hollies, but deciduous types hold great appeal for birds, too—especially for bluebirds, which seem to find holly berries irresistible. Unlike evergreen hollies, some of which can grow to 100 feet tall, deciduous hollies (*Ilex verticillata* and hybrids) are shrubby plants that grow only about 6 to 9 feet tall. 'Winter Red' produces huge amounts of gorgeous, bright red berries on 9-foot-tall plants. If you have a small yard, choose 'Red Sprite,' which grows to just 3 to 5 feet in height.

All of the hollies are perfect for planting in groups or in a mixed border outside the window of your favorite easy chair. Hollies are pollinated by insects rather than wind, so be sure to plant at least one male tree nearby. A nursery center employee may be able to identify the sex of the tree before you buy. Evergreen hollies are hardy to Zone 5; deciduous types are even tougher, thriving as far north as Zone 3.

Sumacs

Sumacs (*Rhus* spp.) get short shrift in most home landscapes, probably because they are such common wild plants. They become part of the backyard scenery, hardly drawing a second glance.

Only in autumn, when sumac leaves become burnished with crimson or orange, and in winter, when their branches stand bare and stark with a candelabra of deep red fruits, can sumacs be considered eye-catching and landscape worthy.

Sumacs flourish from Zones 2 to 10, depending on the species, and in an assortment of conditions. Most grow best in full sun to light shade and are very drought tolerant.

Winter is when sumacs become standouts with birds. Although sumac berries aren't a preferred food, as are acorns or nuts, they are very much appreciated by birds as a meal of last resort. Those spires of fuzzy fruits provide long-term food in the leanest months of the year, when little else is available. Some of the best winter bird watching often can be had from spots that overlook a stand of gangly sumacs.

Viburnums

Viburnums are a diverse group of more than 150 shrubs and small trees. They bear plentiful blooms, and some have fall foliage that's as brilliant as that of a sugar maple. They are fast growing, too, making them fine for a hedge or shrub grouping.

Viburnums differ greatly in hardiness, although most adapt to a range of soil types, moisture levels, and light conditions. Two American natives, nannyberry viburnum (*Viburnum lentago*) and downy arrowwood (*V. dentatum*), are among those that flourish as far north as Zone 2. Others, including many Chinese species and cultivars, are far more tender, surviving only to Zone 9. In general, however, most species are hardy to at least Zone 6.

The berries come in red, blue, and orange, as well as the blue-black of nannyberry and arrowwood. Plant breeders have developed dozens of garden-worthy viburnum cultivars, but the berries of some have lost their appeal to birds. If you want surefire berries for birds, stick to native species, which will thrive naturally in your garden.

More Trees and Shrubs to Attract Birds

Vicki Mattern

These lesser-known landscape plants also are excellent for attracting birds to your yard in winter. Check mail-order catalogs that specialize in native plants.

Manzanitas (*Arctostaphlyos* spp.): Striking, smooth red bark characterizes many of the shrubby species of this western and southwestern genus, which also includes ground-hugging bearberry (*A. uva-ursi*). The red or brown berries are prime food for grouse, grosbeaks, jays, and mockingbirds. (Zones 2 to 6)

Hackberries (*Celtis laevigata*, *C. occidentalis*, and other species): These lovely shade trees have interesting warty gray bark and a multitude of small fruits that ripen in late fall to early winter. Hackberries are a source of food for flickers, jays, mockingbirds, orioles, sapsuckers, thrashers, thrushes, titmice, woodpeckers, and wrens. (Zones 5 to 9 for *C. laevigata*; Zones 2 to 9 for *C. occidentalis*)

California dogwood (*Cornus californica*): This dogwood is a deciduous western native shrub with dark red bark and

Bring In the Birds

Besides providing food for birds this winter, try these additional tips for making your yard a year-round haven for them:

- Offer water. Provide a birdbath or other source of drinking water.
- Make a home. To attract wrens, hang a house with a 1-inch-diameter hole from a branch in a fruit tree 5 to 10 feet above the ground. Bluebirds prefer a house with a 1 1/8-inch-diameter hole mounted on a post 4 to 6 feet above the ground. Robins and swallows prefer an open nesting shelf 6 to 10 feet above the ground.
- Plant a hedgerow. A naturalistic hedgerow will attract those nesting birds that don't use bird boxes.

white berries. It is considered a hybrid of western dogwood (*C. occidentalis*) and red osier dogwood (*C. sericea*) by some taxonomists. Its berries are eaten by songbirds, crows, grouse, quail, and partridges. (Zones 4 to 8)

Persimmons (*Diospyros virginiana, D. texana*): Persimmons are native trees with large, simple leaves and bark that's checkered like an alligator hide. The astringent orange or orange-red fruits are fleshy and turn soft and sweet when ripe. They are beloved by bluebirds, catbirds, mockingbirds, robins, sapsuckers, starlings, and waxwings. (Zones 4 to 9 for *D. virginiana*. Zones 7 to 9 for *D. texana*)

Greenbriers (*Smilax* spp.): These evergreen or deciduous native climbers, some thorny stemmed, are absent in parts of the West but abundant in the southeastern United States. Berries may be yellow, black, blue, or green and are devoured eagerly by many birds. Bluebirds, catbirds, fish crows, flickers, mockingbirds, fox sparrows, white-throated sparrows, thrushes, and pileated woodpeckers are among the prime customers. (Zones 3 to 8)

American cranberry (*Viburnum trilobum*): An eye-catcher in fall, this native bears heavy crops of glowing red fruits. The upright shrub grows to 9 feet in height. Its white spring flowers may have some fragrance; fall color can be striking or muted, in shades of yellow to red. The fruits are attractive to eastern bluebirds, cedar waxwings, bobolinks, cardinals, and mockingbirds. (Zones 2 to 8)

Attracting Songbirds and Hummingbirds

Sally Roth

Birds have a special place in the natural landscape. I can't think of any other wild creatures that will conduct their lives while we watch, but with songbirds, you can share the whole cycle. In spring, you get to welcome them back from migration and watch them in their most colorful plumage as they begin courting and nesting. In summer, there are nests to find and fledglings to enjoy. In autumn, it's feast time as birds stock up for the long flight south.

Birds are a delight any time of year, but it's in winter that I appreciate their presence the most. There's not much to look at in the garden during the bleak, bitter days. Even the clumps of ornamental grass add only a little life, rustling in the cold wind that knifes across the fields. Yet the view out the window isn't all bleak. All I have to do is look over near the bird feeders, under the shrubs, or in the weedy patch beyond the meadow. The garden is sleeping—but the birds sure aren't.

The edges of my big tray feeder are lined with goldfinches in winter, 20 of them at a time, and they're none too polite. They squabble constantly, threatening each other with open wings and open beaks. All in winter plumage now, their soft, green-gold feathers tell the season as sure as any calendar. Right about the time the pussy willows turn from sleek silver to yellow fluff, the goldfinch males will begin to sport an odd blotchy look as their sunny breeding plumage returns.

Along the roof edge, I can see chickadees hanging, waiting for an opening at the feeder. Meanwhile, a pair of white-breasted nuthatches in dapper dress take turns swooping from the oak to the feeder, then back again. Hitching down the trunk in their odd upside-down way, they wedge sunflower seeds into crevices in the bark.

The red-mesh suet bags that hang like cheerful Christmas ornaments from a dozen sturdy shrubs are popular this cold morning. The suet is frozen too hard to dent it with my fingernail, but the woodpeckers hammering away have the perfect chisel-like beaks for the job.

Flowers with long spurs are tailormade for hummingbird bills.

In the brushy part of the garden, where asters and grasses offer seeds and shelter, sparrows and juncos are scratching away, kicking up clods of frozen-together leaves as they search for morsels. I turn away to freshen my coffee and come back to find a male bluebird on the holly, carrying the sky on his back, as Thoreau said,

though today the real horizon is drab gray instead of azure. The bluebird is soon joined by his mate and the three youngsters from this year's brood. They pick off one berry after another, methodically stripping the stems. I catch myself thinking, Hey, don't eat so fast!, and then I laugh. That's what they're there for, after all.

Meeting Birds' Needs

It's easy to attract birds to your garden. All you have to do is put up a feeder. But feeder birds zip in, eat, and zip back out. To keep them in your garden, you'll have to fill more than one basic need.

Food, water, and shelter are the big three. In addition, your birds will need corridors of cover to move safely from one part of the garden to another. Birds are too close for comfort to the bottom of the food chain, and without adequate cover, your guests will still be eat-and-run types. You'll have to think like a bird if you want to make them feel at ease in your garden.

The downy woodpecker is common in farm country and suburbs throughout North America, wherever large trees are found. In the wild, they nest in cavities in dead branches on otherwise live trees, but they'll quickly accept a loglike nest box with a handful of sawdust on the bottom.

Creating Cover

You'd be surprised by how little cover many birds need. A split-rail fence provides no shelter, but if you let grasses and wildflowers grow up around the bottom of it, birds can use that thin strip to travel at will. Instead of isolating your feeders, surround them with sheltering shrubs that let birds move safely to berry bushes or to the water garden.

Often in winter, our feeder becomes a regular stopping point for a Cooper's hawk, a slim, steel-gray songbird-eater that used to go by the old nickname "blue death." Evidently, these predators, which usually keep to the forests, have learned about the easy pickings a feeder attracts. I see them even in cities, patrolling neighborhoods for a likely feeder.

Without cover, songbirds at a feeder are sitting ducks. Cooper's hawks are swift and agile, and a chickadee is no match for them. To even the game, I always park our discarded Christmas tree on its side next to the feeders for the duration of the winter. It may not be pretty, but to the birds, it makes the difference between life and death.

More than once, I've watched the hawk perch on the Christmas tree and carefully extend a claw down into the branches to try to nab its prey. If the birds sat tight, they were safe. But sometimes a sparrow or junco became unnerved and fled in terror, becoming an instant dinner for Mr. Hawk.

Watch a flock of native sparrows or wood warblers fly across open ground, and you'll see that they don't fly in a straight line. The birds fly as fast as they can, twisting and dodging in flight. It's as difficult to follow a single bird with your eyes as it is a snowflake in a blizzard. That indirect flight is for a good reason: It's just as hard for a hawk to pick out or pick off a single individual as it is for your eyes to follow it.

The best way to provide cover for birds is to provide connected plantings so birds never need to come out in the open. Plan your garden as a series of linked sites, joined together by protective grassy or weedy patches or by brush or evergreens. Think of the corridors of plants in your garden as bird paths. They're essential to making feathered visitors feel at home.

What's on the Menu?

I keep the menu simple at my bird feeding station: Sunflower seeds, white millet, and suet are the staples. Sunflower seeds will appeal to most of the customers, and millet will bring in the smaller seedeaters who can't crack the big sunflower seeds. The suet takes care of woodpeckers and others that prefer soft food.

I also keep tube feeders filled with niger, the tiny black seed that used to be called thistle, but which is actually *Guitzotia abyssinica*, a sunflower relative with small yellow flowers. For high nutrition and high fat, I serve peanut butter straight from the jar, smeared on the roofs of the feeders. (Contrary to popular belief, there's no danger of suffocation from birds eating straight peanut butter, according to ornithologists at Cornell University.)

Like any good restaurateur, I offer frequent specials at the bird café. Sometimes hulled sunflower chips are on the menu. Occasionally there's expensive canary seed, a real treat for finches, or a handout of peanuts, walnuts, or pecans picked up along the road here where the trees grow wild. In winter, when the cardinal customers swell from the 10 regulars to a horde of 70 or more, I start hauling in hundred-pound sacks of cracked corn. Starlings love it, too, but it's cheap enough to share.

Continued

Food for All Seasons

Since food is the primary attraction, the first thing you'll want to do is provide an assortment. Like us, different birds prefer different types of food. I keep my feeders well stocked year-round, but I also fill my garden with live, growing bird treats.

I grow lots of berried shrubs, but I also plant a lot of grasses and flowers for the birds. Grains and sunflowers are staples in the bird garden, just as at the feeder. In spring, I scratch up sunny ground and scatter white millet, straight from the birdseed sack. I plant extra-thick, so the millet looks like a lush bed of green grass. By midsummer, the seedheads are showing. Goldfinches and others begin nibbling long before they turn golden. Foxtail grasses, wild oats, and other natives sprinkle the garden and fill in the gaps between shrub plantings. They do double duty—no, triple duty—by supplying cover and nesting material as well as food.

Sunflowers are another item that's perennially on the garden menu. When I moved to the Midwest, I discovered dozens of perennial species of sunflowers, native prairie flowers that are equally at home in a naturalistic garden. Most perennial sunflowers are spreaders, but that's okay with me—and with the birds. The tasty seeds of Maximilian sunflower, sawtooth sunflower, and others attract birds well into late fall.

I tried to plan for all-year good taste when I selected berry bushes for my garden. Some fruit ripens in late summer, just in time to catch the eye of refueling migrants. Other berries are at their peak in fall, and some are ignored by birds until winter hunger drives them to search out the last fruits left on the trees and bushes.

At the Feeder

Watching birds at a feeder is a great way to spend an hour or an afternoon. It's so soothing that some institutes use it as a meditative therapy for their clients. Enjoying the birds at my feeders is as much a part of my morning routine as a cup of coffee. I can't imagine starting the day without either one.

A feeding station is also a great way to learn to identify birds. Instead of a hundred or more species flitting through the leaves in a May woods, there's only a handful, and they're in plain view. Be sure to establish your station close to a window where you can easily watch sitting in your favorite chair—I can see my feeders from my kitchen table.

My first bird feeder was a simple open tray, knocked together out of scrap lumber. Twenty years later, the most-used feeder in my collection is one of that same simple design.

The more aggressive birds can monopolize a feeder, so I keep several filled. If blue jays take over one of the feeders, the shyer chickadees and titmice can visit another.

You can get as fancy as you like with feeders, from copper-roof cupolas to white-column palaces that would cost more than my birdseed budget for a year. But before you succumb to a fancy feeder, think about how you'll fill and clean it. A pretty cedar pagoda dangles from a post in my yard, but it's almost always empty. To fill it requires me to balance a cup of birdseed in my teeth while I slide open a glass door with one hand and try to keep the whole shebang from tipping over with the other. Pretty is as pretty does, as your grandma probably told you.

A tube feeder, whether it's stocked with niger seed or sunflower, will attract finches. Here a trio of species—house finches, goldfinches, and pine siskins—dine together.

Many birds prefer an open tray, perhaps because their exits are unimpeded and they have a good view of approaching predators. You can make one easily—it's a great project for kids. Use hardware cloth for the bottom, so rainwater can drain easily. I keep the sides on mine as low as possible, so I can see the birds better. A low tray feeder that stands on the ground with short feet will serve ground-feeding birds like doves and sparrows and keep the seed off the wet ground. A tray attached to a tree trunk will attract everything from jays to juncos.

Finches, siskins, titmice, and (sometimes) chickadees visit hanging tube feeders, which offer a limited number of perches but conserve seed and protect it from moisture. Don't go the cheap route when you buy a tube feeder: You'll pay for it in spilled birdseed. Those with heavy metal bases and seed-cup holes are more stable in the wind, and that means less seed wasted on the ground. If house finches have overrun your tube feeders, buy one with perches above the holes. Acrobatic goldfinches will have no trouble reaching them, but house finches will be stymied.

Water—It's Essential

If you provide clean water, you'll give birds another reason to linger in your garden. Birds love a birdbath all year long, even in the coldest days of winter. It removes dust and parasites from

Golden Bounty

The best sunflower I've ever found for birds is the tickseed sunflower (*Bidens aristosa*). Despite its name, it isn't an annoyance to socks or dogs because the seeds lack the stick-tight prongs of other members of the genus.

This is an annual plant native to eastern North America, and it's a beauty. It grows into a 4-foot-tall plant, branched and bushy, with ferny leaves that look a little too much like marijuana. (Just ignore your neighbors' funny looks.) It blooms late, about August, and cloaks itself in hundreds of small golden daisies. The flowers have a delicate look and texture, more like cosmos than traditional sunflowers. They smell sweet and attract even more butterflies than butterfly bush.

But it's the abundant seeds that are the real pay-off. From September through spring, my stand of tickseeds attracts sparrows, juncos, titmice, chickadees, goldfinches, and other small birds. The birds hang on the seedheads like parrots or scratch the ground beneath for dropped crumbs. The plants seed themselves with abandon, but I don't mind. Unwanted seedlings are easy to pull out or smother with mulch.

Plant tickseed sunflower where it can sow itself freely for a bounty of golden bloom, or grow it in a big pot with morning glories or cypress vine.

their feathers, and it probably feels good, too—they revel in splashing as much as any two-year-old.

A shallow, rough-bottom container is a perfect choice, but birds can make do with just about anything. I keep a bucket of water filled outside for our dogs, and I've seen house finches, chickadees, and other birds using it, too. Up the road at the horse barn, bluebirds line up on the edge of a deep metal trough, sipping daintily.

The traditional birdbath is still a good design, but after two pedestals were broken by my rowdy dogs, I switched to using only the tops. I have three basins in the garden, each set on a flat rock about 6 inches tall. The one that gets the most use is almost hidden from view, beneath an exuberant arch of boltonia stems. In spring, when the vegetation is cleared away, the birds are more wary about bathing.

A naturally hollowed-out stone that's cupped to form a shallow basin makes a good birdbath. Another birdbath alternative is a simple large clay saucer, if you set a flat, rough stone into it to provide better footing. Of course, a garden pond or stream is better yet.

Once the birds discover their bath, they'll be regulars. It's my guess that that's why pedestal-type baths attract birds so quickly: Like red plastic hummingbird feeders, the birds are used to seeing them—they know what that shape means.

If you have an outdoor electrical outlet, you can use an immersible water heater to keep your birdbath in use all winter. They cost as little as $15 at pet- and pool-supply stores and are simple to install: Lay the heater in the birdbath, plug it in, and you're set. If you need an extension cord to get from outlet to birdbath, be sure to buy a heavy-duty cord suitable for outdoor use.

The sound of splashing water will catch the ear of passing migrants who might otherwise overlook your birdbath. You can rig up a slow-dripping bucket from a branch and set your birdbath under it, or you can invest in a recirculating pump (about $50) and spend a few hours creating a gentle murmur of water.

Birds especially appreciate a source of fresh water in winter, when natural ponds and puddles are frozen over. Simply lay an electric heater in your birdbath to keep it ice-free.

Giving Your Birds Shelter

Shelter from the wind and weather and from predators is the last element of the bird garden. Evergreens are ideal bird shelters. An eastern red cedar that stands at the corner of my garden is home to dozens of birds every night: If you stand close to it, you can hear their sleepy twitters as they settle down for the night, safe from predators who won't risk its prickly branches.

A single evergreen will offer some shelter, but a group planting is better for cardinals and other birds that flock and

Continued →

Fruit for All Seasons

To plant a larder that will sustain birds for months, plan your fruit-bearing plantings around these seasonal treats.

Spring

Birds are looking for soft foods in spring, and they're abundant. Caterpillars and insects fill the bill nicely (and literally), with no assistance from you. A well-planted garden, full of young trees and a diversity of shrubs, will naturally attract insects, and that's what will draw the birds.

You can supplement the insect diet with strawberries. Plant a bed or a border of them just for the birds. Wild strawberries provide the perfect-size fruits for birds, and the plants make an appealing groundcover. The familiar wild strawberry that I gathered and made into bouquets of berries as a child is ideal. Alpine strawberries, which grow in self-contained tuffets, are a good choice, too, and so are Western beach strawberries. They're native to the West Coast, but they grow well in other regions, and their shiny leaves are as ornamental as wild ginger.

Summer

Summer kicks fruit season into high gear. Anything you like to eat, birds do, too. Sour cherries, pin cherries, and other cherry trees are great for the bird-friendly garden. Plums, apricots, and peaches are also good bird attractors. When our peach tree surprised us with a bumper crop one summer, the house finches made short work of the fruits at the top of the unpruned tree. They puncture the fruit to drink the sweet juice.

Add some raspberries and blackberries to your hedges, and plant river grapes, fox grapes, or Concords to clamber up trees and over trellises. Blueberries are superb bird fruits. Elderberries offer dinner plate–size heads of delectable, tiny berries, relished by waxwings, thrushes, robins, and other birds. Try blue or red elders for a change of pace. The bushes are more substantial than common elderberry, and the crop sustains birds for weeks.

Fall

Fall is viburnum time! There are dozens of species, and the fruits of all of them are appreciated by birds. I find that the birds pick the berries off the arrowwood first; then they turn to gray dogwood and American cranberrybush viburnums. Sumacs are welcomed, too. I prefer the look of shining sumac in the garden. Its winged stems hold glossy leaves that turn fire-engine red in autumn and shine like a beacon until they drop. Bluebirds are especially fond of sumac fruits.

If you don't mind its self-sowing tendencies, and if you have birds visiting your yard, you probably already have some pokeweed. The stems turn Day-Glo purple in fall, and the clusters of black berries disappear fast when migrating birds discover them.

Winter

Now the birds turn to the last of the berry crop. They seek out the hanging, ¼-inch berries of hackberry trees, and they clean the clusters of showy orange fruits from the pyracantha that climbs the chimney. Cotoneasters also draw them in. And hollies of all kinds are eaten with relish. Roving flocks of waxwings visit the garden, searching out the last of the pokeweed and any remaining viburnum or sumac berries. Hawthorns shine like an "Eat at Joe's" sign. Crabapples, ignored by most birds until winter, become a fruit of choice. Hybrid varieties are often passed over by birds (my guess is that they just don't taste good), but the shriveled fruit that hangs from the wild crabs in my garden draws house finches, bluebirds, tufted titmice, mockingbirds and other fruit-eaters.

Mockingbirds thrive in areas with few trees, dense shrubbery, and lots of edible fruits like these bittersweet berries.

roost together in winter. Many of the plants that you choose for food value will do double duty as shelter. Plant for diversity, mixing plant types and heights as they would be in nature. But remember to keep some open areas between shrub groupings so that you can still watch the birds!

Nest Boxes—Instant Homes

It's exciting to put up a nest box and watch to see who moves in. You can buy nest boxes or nest box kits, but they're also a fun project for families to build together from scratch. Birds are pretty forgiving when it comes to carpentry mistakes. They won't mind the crooked nail or the slightly off-center hole. Nest boxes also provide winter shelter. Or you can make a roost box for birds seeking shelter in winter—it looks like an elongated nest box with the entrance hole at the bottom. Birds that don't nest in cavities won't nest in your boxes, but they may turn to your trees and shrubs as a safe haven to build their nests. Try to avoid the temptation to take a peck—your scent leaves a clear trail for predators.

Recipe for Bluebirds

I'm not much of a cook, but for birds, I pull out all the stops. Last winter, when deep snow hit the lower Midwest, bluebirds came in to my feeders in droves. They'd never visited the feeders before, though they had come for berries in the garden. I was stunned by their beauty—such an intense blue against the fresh snow.

Ransacking the pantry, I pulled out cornmeal, a jar of chunky peanut butter, and a bottle of corn oil. I mushed it up to crumbly cookie-dough consistency, then took it outside. The bluebirds moved off only a few feet. When I scattered the dough on the porch where it would be protected from the snow, they immediately returned, fluttering down right at my feet. What a magic day, standing in the midst of bluebirds and falling snow.

Here's my "magic bluebird" recipe:

Peanut-Butter Dough

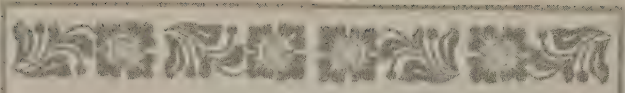
6 cups yellow cornmeal

18-ounce jar chunky peanut butter

6 small boxes of raisins, chopped with a floured knife (optional)

1 cup corn oil

Mix by hand. Adjust proportions of cornmeal and peanut butter if needed until dough reaches a lumpy but crumbly consistency.



Nesting Materials

Bird-feeder traffic drops off dramatically in spring, when birds begin nesting. Instead of trying to entice birds to your yard with food, offer them some tempting nesting materials.

Scatter the items on an open area or drape them over shrubs. I like to tease the orioles by tying butcher string onto twigs. They're as adept as Boy Scouts at undoing the knots.

Here are some nest-material options, in order of their desirability:

- White duck or goose breast feathers (cannibalize an old bed pillow, ask at a farm, or check a duck pond)
- Other colors of breast feathers (breast feathers are the curled ones, wide and soft at the end)
- Goose or duck down
- Short lengths of white butcher string (no longer than 8 inches to prevent mishaps)
- Short lengths of other string or yarn
- Horsehair from mane or tail
- Rabbit and opossum fur (check a thrift shop for an old fur coat or collar, nail a strip to a board, and mount on a tree)
- Dog fur

You can also offer dried grass blades, fine twigs, bark strips (grapevines are a great source), and spaghnum moss, but birds often prefer to collect their own.

There's another trick you can use to attract nesting birds: Keep a mud puddle fresh and wet. Nest-building swallows, robins, and other birds can travel for great distances to collect mud in times of drought.

Hummingbirds in Your Garden

Hummingbirds are easy to bring to your garden, even if you live right in the middle of a city. These little zippers come to our yards for one big reason: to eat. It takes a lot of sugar to keep a hummingbird's energy up.

The ruby-throated hummingbird is the only species that makes its home east of the Mississippi, though strays of other species may turn up from time to time. Go west, and you'll find hummers with pink, purple, blue, and orange feathers. That iridescent flash of color comes from tiny feathers called gorgets.

If you're planning a camping trip to Texas or west of the Great Plains, take along a hummingbird feeder and a couple of packets of instant nectar. Hang it at your campground, and you're in for a treat.

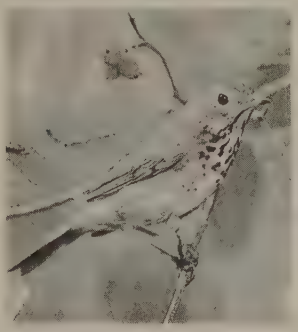
Songbirds in Your Garden

I didn't realize how different birdlife can be until I moved from the East to the Pacific Northwest and set up my first bird feeder. There was nary a blue jay in sight, though the elegant midnight-blue Steller's jay was a fine substitute. Cardinals, which I'd taken for granted, never managed to cross the Rockies. But I did host varied thrushes, like robins but dressed in gorgeous golden orange and blue, and a throng of ruddy brown western fox sparrows. It was an education.

The songbirds you find in your garden will depend on where you live, what kind of habitat you provide, and what kind of habitat is nearby. Here are some of the birds that may turn up in your garden.



Hermit thrush (above), Purple finch (below)

EAST

Northern bobwhite
Mourning dove
Golden-shafted flicker
Red-bellied woodpecker
Downy woodpecker
Hairy woodpecker
Eastern phoebe
Blue jay
Black-capped chickadee
Tufted titmouse
White-breasted nuthatch
House wren
Mockingbird
Gray catbird
Brown thrasher
Robin
Veery
Eastern bluebird
Blue-gray gnatcatcher
Wood thrush
Hermit thrush
Cedar waxwing
White-eyed vireo
Red-eyed vireo
Warbling vireo
Yellow warbler
Yellow-rumped warbler
Black-throated green warbler
Ovenbird
Common yellowthroat
Kentucky warbler
Eastern meadowlark
Red-winged blackbird
Common grackle
Brown-headed cowbird
Baltimore oriole
Scarlet tanager
Cardinal
Rose-breasted grosbeak
Indigo bunting
House finch
Goldfinch
Rufous-sided towhee
Chipping sparrow
Field sparrow
Swamp sparrow
Song sparrow

In winter:

Red-breasted nuthatch
Brown creeper
Golden-crowned kinglet
Ruby-crowned kinglet
Purple finch
Dark-eyed junco, slate-colored race
White-throated sparrow
White-crowned sparrow
Tree sparrow
Fox sparrow
Evening grosbeak
Purple finch
Pine siskin

SOUTH

Northern bobwhite
Mourning dove
Golden-shafted flicker
Red-bellied woodpecker
Downy woodpecker
Hairy woodpecker
Eastern phoebe
Blue jay
Carolina chickadee
Tufted titmouse
White-breasted nuthatch
Brown-headed nuthatch
House wren
Winter wren
Carolina wren
Mockingbird
Gray catbird
Brown thrasher
Robin
Eastern bluebird
Wood thrush
Hermit thrush
Blue-gray gnatcatcher
Cedar waxwing
White-eyed vireo
Red-eyed vireo
Northern parula warbler
Yellow warbler
Yellow-rumped warbler
Pine warbler
Common yellowthroat
Kentucky warbler
Eastern meadowlark
Red-winged blackbird
Rusty blackbird
Brewer's blackbird
Common grackle
Brown-headed cowbird
Baltimore oriole
Scarlet tanager
Summer tanager
Cardinal
Blue grosbeak
Indigo bunting
Painted bunting
House finch
Goldfinch
Rufous-sided towhee
Chipping sparrow
Field sparrow
Song sparrow

In winter:

Red-breasted nuthatch
Brown creeper
Dark-eyed junco, slate-colored race
White-throated sparrow
White-crowned sparrow
Swamp sparrow
Fox sparrow

Evening grosbeak
Purple finch
Pine siskin

MIDWEST

Northern bobwhite
Mourning dove
Golden-shafted flicker
Red-shafted flicker
Red-bellied woodpecker
Downy woodpecker
Hairy woodpecker
Golden-shafted flicker
Eastern phoebe
Say's phoebe
Blue jay
Black-capped chickadee
Tufted titmouse
White-breasted nuthatch
House wren
Bewick's wren
Carolina wren
Mockingbird
Gray catbird
Brown thrasher
Robin
Eastern bluebird
Wood thrush
Blue-gray gnatcatcher
Cedar waxwing
White-eyed vireo
Bell's vireo
Red-eyed vireo
Warbling vireo
Yellow warbler
Yellow-rumped warbler
Ovenbird
Common yellowthroat
Kentucky warbler
Eastern meadowlark
Western meadowlark
Yellow-headed blackbird
Red-winged blackbird
Rusty blackbird

Brewer's blackbird
Common grackle
Brown-headed cowbird

Common yellowthroat (above), Red-bellied woodpecker (below)

Baltimore oriole
Western tanager
Scarlet tanager

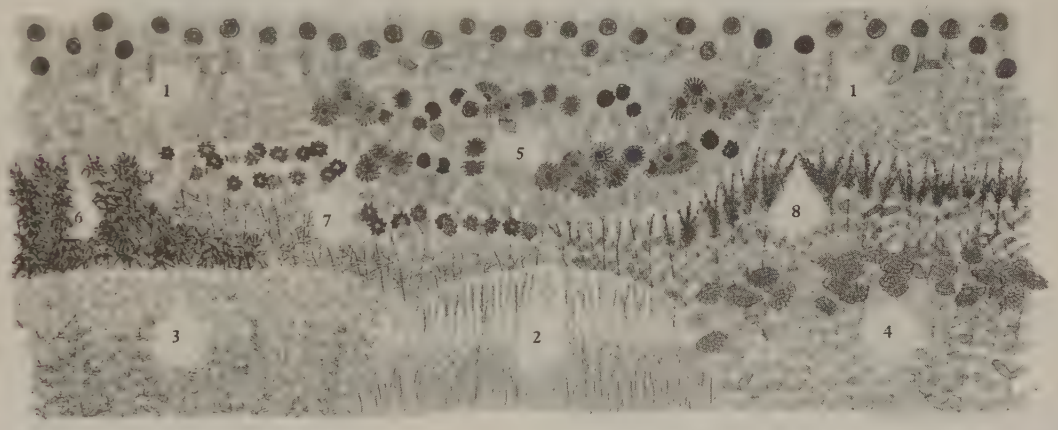
A Birdseed Garden

Seed-eating birds will forage for months in a garden full of naturally appealing foods. Let the stalks stand in winter—birds will continue to glean seeds and insects through the seasons, and sparrows will scratch around beneath the plants for any morsels that may have dropped. Many of the best birdseed plants are those we're used to thinking of as weeds. But if you've ever scared up a batch of sparrows from a weedy field, you know how attractive these plants are. That's because they're chock-full of seeds—and that's exactly why they're weeds. The prodigious seeds spread the plants throughout farm fields, roadsides, and other disturbed ground. As far as the birds are concerned, it's all easy pickin's. This garden uses some of the prettier self-sowing plants, and the birds should clean off the seeds well enough to keep them from being too "weedy."

Plant List

1. "Russian Mammoth" sunflowers (*Helianthus annuus* "Russian Mammoth") with false climbing buckwheat (*Polygonum scandens*) and grain buckwheat (*Fagopyrum esculentum*)
2. Foxtail millet (*Setaria italica*)
3. Tickseed sunflowers (*Bidens aristosa*)
4. Zinnias (*Zinnia elegans*)
5. "Autumn Beauty" and "Music Box" sunflowers (*Helianthus annuus* "Autumn Beauty" and *H. annuus* "Music Box")
6. Lamb's quarters (*Chenopodium album*)
7. "Sensation" cosmos (*Cosmos bipinnatus* "Sensation")
8. Amaranths (*Amaranthus* spp.)



I remember babbling to a ranger in the southwestern mountains about a hummingbird I'd seen in the pines. It was just gorgeous, I said, all green and purple and blue. What was it?

"That's a magnificent hummingbird," the ranger replied.

"Sure is," I agreed enthusiastically. "But what is it called?"

The ranger laughed. "That's its name," he said, "the magnificent hummingbird."

SEEING RED

Red is the key to attracting hummers. They can't resist investigating anything red or orange, from the handles of my favorite pruners to the jumpsuits worn by scientists on Mount St. Helens after the volcano. (The hummingbirds probed the grommets, trying to figure out how to get nectar out of the protective suits.)

If you haven't had hummingbirds in your garden before, start by making a big splash of red. Put out a dozen zingy geraniums and a plastic hummingbird feeder—the gaudier the better. Once you have hummers coming regularly, you can switch to a more subtle feeder design. But for starters, go for something good and tacky, like a big, red plastic strawberry.

The ruby-throated hummingbird, which ranges across the eastern half of the country, is attracted to orange or red flowers like this trumpetvine. Its rapid wingbeats—up to 75 times per second—make it an avian helicopter.

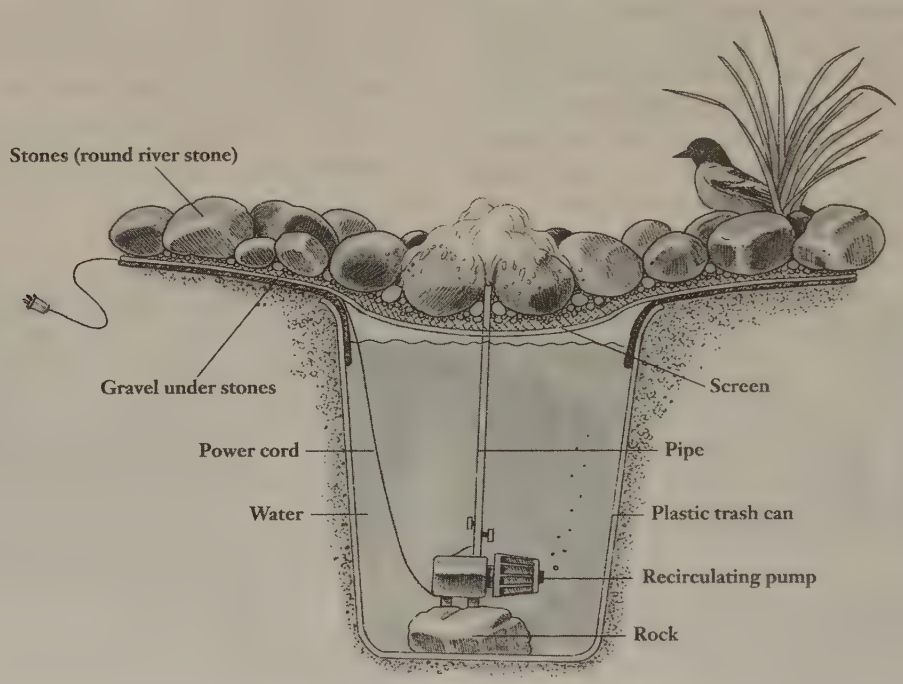
Installing a Bubbling Spring for Birds

One of the prettiest birdbaths I've ever seen was a simple homemade "spring"—a collection of rounded river stones set on a bed of gravel, piped with a recirculating pump. Water bubbled up through the stones just like a real spring, spreading out between them to create shallow places for birds to sip or splash. A semicircle of larger rocks surrounded the spring and sheltered ferns.

The trick to the arrangement was a small plastic trash can buried at the center of the stones, which sloped slightly downward to a center depression above the can. Topped with a sturdy metal grid, that can held the pump and the pipe that carried the water in the can to the surface. A layer of pond liner under the gravel beneath the stones collected the water and returned it to the buried can.



A HUMMINGBIRD GARDEN

Hummingbirds are fast eaters, and they usually zip in and out pretty quickly at the feeder. To get them to linger, you can plant a hummingbird garden.

Think of that beak when you choose flowers: Hummingbirds naturally prefer flowers with long tubes, where sweet nectar awaits. Tubed blossoms (think of a trumpetvine or honeysuckle flower) or spurred flowers (think of a columbine) are great enticements. It's a win-win thing for both bird and blossom: The hummer gets the nectar, and the flower gets pollinated. Sometimes I see hummers with their heads dusted yellow with pollen. Hummers will notice tubular blossoms before you do. You've probably never thought of the herb sage as having a tubular flower, but take another look. Hummingbirds certainly do—they enjoy both culinary sage and its ornamental relatives, the salvias. Bee balm is another hummingbird favorite, and, of course, the hummers like the reddest varieties best.

Hummingbirds often make a garden their home if it includes a good-size tree where they can mount their tiny, cuplike nest of spider silk and lichens. If you see a hummer going from one spiderweb to another in your garden, watch to see whether it's picking out tiny insects or whether it's collecting silk. Then good luck trying to follow it with your eyes to a nest site!

Hummingbirds are beautiful, but they're also bullies. Not only do they claim breeding territories, but they also claim food sources—a feeder, a fuchsia, or a pot of geraniums—as their own. And they'll guard them from anybody, including humans and dogs.

I once watched a single hummingbird drive away a flock of 30-plus cedar waxwings. The waxwings were flycatching over a stream; the hummer was drinking nectar from the orange jewelweed flowers along its edge. Every time a waxwing flew out, the hummingbird zoomed to the attack, chasing the much larger bird out of sight. After several such forays, the waxwings gave up and retreated en masse.

On migration, hummingbirds follow a path of red flowers when they head north. When my flowering quince comes into bloom, I hang out the feeder. In the Pacific Northwest, it was the blossoming of the red-flowering currant, a sinuous, lovely,

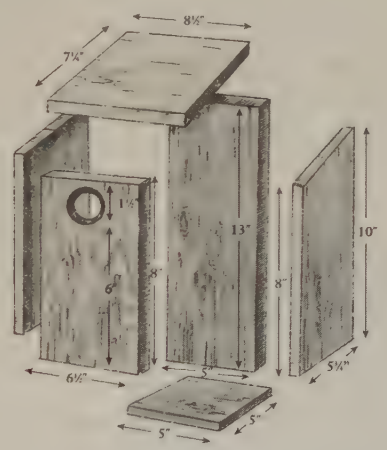
Building a Bluebird Nest Box

Bluebird boxes are popular with backyard birdwatchers for one very good reason: They work. Bluebirds like open spaces, with woods or hedgerows nearby. They like farmland and suburban areas, and are partial to golf courses and cemeteries. If you have a suitable bluebird habitat in your yard or nearby, the chances of a box attracting a nesting pair are very good.

Building birdhouses is a great family activity, and you don't need to be a master carpenter to be successful at it. All you need is a saw, a drill, a hammer, and some nails. A pair of hinges and a hook and eye attached to one side will let you open the box for easy cleaning. Affix the floor 3" from the bottom of the nest box back, and mount the box by drilling two holes through the "apron" of wood left at the bottom.

If your workshop is really minimal, you can have the boards sawed to size at a home building supply store. However, an electric saw is fairly inexpensive and worth it if you're building more than one house.

Other birds, including titmice, nuthatches, and chickadees, may also be interested in your bluebird house. Why not make several?



You can vary the dimensions of a bluebird box somewhat, but don't change the size of the hole. Any bigger, and it will allow entrance to starlings. Mount the box 4–8' above the ground.

native shrub, that told me when to expect the first tiny guests. Of course, in mild climates such as the Southwest or Southern California, hummingbirds are a year-round pleasure. I'll never forget drinking a New Year's Day toast while watching hummers zip around the flowers of a blooming bottlebrush tree in a Los Angeles backyard. It was just another part of the everyday magic that happens when you garden for the birds.

Brilliant Bird Gardens

Joan Benjamin and Deborah L. Martin

Discover wonderful ways to bring more color and life into your gardens (and a little creature company, too!). From far-out feeders to flower favorites, find out how to entice your favorite birds to your backyard and provide food, water, and cover for your feathered friends. You'll discover that the right selection of plants is the easiest way to attract an interesting array of birds. To lure eye-catching butterflies to your flower garden, follow these gardener-tested tips and techniques that will bring flutters of brilliant color all season long.

Compass Plants Have Impact

"Birds love the seeds of the compass plant," says Jim Becker, who gardens with birds in mind in Oregon. The compass plant looks something like a giant yellow hollyhock from a distance, with a spire of golden daisy flowers that can grow to reach 8 feet tall. An imposing clump makes a grand statement beside a garden gate—but make sure it's in easy view of an indoor window so that you can enjoy the parade of finches, juncos, sparrows, downy woodpeckers, and other seed-eaters who will be stopping by all fall and winter. Compass plant (*Silphium laciniatum*) grows best in moist, well-drained, humus-rich soil in full sun.

Christmas Celebrations

Winter birds love a Christmas feast even after the holiday. Set your Christmas tree outside where it's sheltered from the wind,

Nectar Recipe

Instant nectar, available wherever hummingbird feeders are sold, is fast and easy to make. But it's super-expensive when you compare it with the cost of making your own, and the red dye often used is unnecessary and unhealthful. (Use red on the feeder, not in the nectar, to attract your hummers.)

Nectar is nothing more than sugar water. For every 4 parts water, add 1 part sugar. For easy refills, mix up a gallon jug and store in your fridge.

My feeders hold about 2 cups of nectar. When they need refilling, I measure out ½ cup of white granulated sugar, then pour 2 cups of boiling water over it. I stir to mix and let it cool before filling.

Don't add red food coloring, and don't use honey. Both can cause health problems for your hummers.

Superfine white sugar, which you can find at some supermarkets and at bar-supply stores, dissolves instantly even in cold water, but it costs more than granulated sugar.

Continued →

A Hummingbird Garden

No hummingbird can resist a splashy display of brightly colored flowers and nectar-rich blossoms. This garden will bloom from spring to frost, so visiting hummers will always find something to feast upon. Wild columbine and flowering quince start the season, offering their blossoms to the first of the migrants. Rose-of-Sharon, petunias, and many other flowers are in full tilt right at nesting time, so there's plenty of high-energy food. Late-bloomers like pineapple sage make sure there's still an abundance for fall migrants.

Long-blooming annuals and tender perennials like impatiens and geraniums are a staple in the hummingbird garden, because their flowers keep going for months without letting up. Plant your favorite color of garden-center petunias the first year. Then let them self-sow. They'll revert to the species form, a vigorous plant with simple, fragrant blossoms of white, lavender, and pink-purple.

Red flowers in this garden act as a hummingbird magnet. Once the tiny birds have found your special spot, tubular blossoms will encourage them to linger.

Plant List

1. White-flowering rose-of-Sharon (*Hibiscus syriacus*)
2. Cypress vine (*Ipomoea quamoclit*) with white- and blue-flowering morning glories (*Ipomoea* tricolor 'Pearly Gates' and 'Heavenly Blue')
3. Potted red-flowered geranium (*Pelargonium* x *hortorum*)
4. Pineapple sage (*Salvia elegans*)
5. Blue-flowered delphinium (*Delphinium belladonna*)
6. Flowering tobacco (*Nicotiana sylvestris*)
7. Self-sown (species) petunias (*Petunia integrifolia*)
8. 'Grandview Scarlet' bee balm (*Monarda didyma* 'Grandview Scarlet')
9. Anise hyssop (*Agastache foeniculum*)
10. Salmon-rose 'Picasso' geraniums (*Pelargonium hortorum* 'Picasso')
11. Golden columbine (*Aquilegia chrysantha*)
12. Hardy fuchsia (*Fuchsia magellanica*)
13. Red buckeye (*Aesculus pavia*)
14. White-flowered impatiens (*Impatiens walleriana*)
15. 'Homestead Purple' rose verbena (*Verbena canadensis* 'Homestead Purple')
16. California fuchsia (*Zauschneria californica*)
17. Apple-scented geraniums (*Pelargonium odoratissimum*)
18. Red- and salmon-flowered Texas sage (*Salvia coccinea* species form or 'Lady in Red' for red flowers and *S. coccinea* 'Cherry Blossom' for salmon flowers)
19. Great blue lobelia (*Lobelia syphilitica*)
20. Blue-flowered larkspur (*Consolida ambigua*)
21. Wild columbine (*Aquilegia canadensis*)
22. Coral bells (*Heuchera sanguinea*)
23. Flowering quince (*Chaenomeles speciosa*)

then gather leftovers from holiday baking to make garlands of raisins, nuts, and dried fruit slices. Fill citrus rinds with peanut butter and fruit for ornaments.

Birds Love Love-Lies-Bleeding

Let things go to seed in your garden and you'll be surprised at the birds you attract, says Jim Becker, co-owner of Goodwin Creek Gardens in Williams, Oregon. "We grow amaranth and a decorative millet and sell the seeds, and we have to cover the plants when the seeds are ripe to fight off sparrows and juncos. But the birds love the seeds so much that we always leave some for them when we're done harvesting," says Jim.

Jim and his wife, Dottie, grow love-lies-bleeding (*Amaranthus caudatus*), an annual with long strands of deep pink flowers that look like thick, soft yarn, and 'Hopi Dye' amaranth, an upright, plumey type. "Both amaranths are great for dried flowers as well as for birdseed," Jim says.

Sow seeds outdoors after all danger of frost has passed and the soil is warm. Amaranth will ripen most of its grain 90 days after sowing.

With Bird Feeders, Bigger Is Better

When you're hosting a lot of backyard birds, a feeder can empty quickly as hungry beaks snatch up sunflower seeds and other morsels. Save time refilling feeders by choosing large-capacity feeders that hold more seed. One ingenious option is hopper feeders that refill themselves as the seed level drops. Hopper feeders prevent waste, too, because windy, rainy weather doesn't soak the whole buffet, only the portion that's in the tray of the feeder.

Betsy Colwell, president of Droll Yankees, a company that's been making high-quality bird feeders for decades, says her favorite feeder is a large hopper model called the Jagunda. "I'm busy all week," she says, "so I can fill it up at the beginning of the week and not have to refill it until the weekend." When birds are depending on your banquet, a big feeder means they won't go away hungry when supplies run out and you're not home.

An A-maize-ing Hedge for Birds

Pauline Hoehn Gerard of Henderson, Kentucky, wanted to keep alive her memories of her childhood farm, so she planted a triple row of corn along her property line. "I planned to pick the ears for decorations, but the birds beat me to it. We had cardinals galore, blue jays, blackbirds, even woodpeckers feasting on our corn hedge," she says.

Pauline says she loves watching corn grow, and she needed a quick-growing hedge for privacy at her new home. Her corn grew quickly to towering heights, giving her home a farmlike feel, along with protection from prying eyes, and brought with it the added bonus of fun-to-watch birds at harvest-time.

Back-to-Back for Bluebirds

Bluebirds often face very stiff competition for birdhouses, especially from tree swallows. Since bluebirds aren't aggressive, the swallows usually end up with possession of the houses, but David H. Drake, president of Coveside Conservation Products, a birdhouse manufacturing company, says the solution is simple.

"Mount two bluebird houses back to back or very close together, and tree swallows and bluebirds will live happily as neighbors."

The key to this idea's success is knowing that birds of the same species, like two families of tree swallows, won't nest in adjoining apartments, even though they will nest as nearby neighbors. By putting the houses back to back, you play on the tree swallows' natural instinct not to share space. Birds of different species, however, will coexist contentedly even if their homes are very close together.

Feature the Food Chain

Prairie wildflowers, like coneflowers (*Echinacea* and *Ratibida* spp.), Joe-Pye weed (*Eupatorium* spp.), and many others, not only produce edible seeds for birds but are also unparalleled at attracting

Choosing a Hummingbird Feeder

Hummingbird feeders have come a long way in the last ten years or so, but designers still don't have the message that form follows function. A feeder must be easy to refill and easy to clean, since you'll be doing both frequently. If your garden is graced with hummingbirds, you can count on refilling the feeder at least once a week.

Molds are unhealthy to hummers, so keeping your feeder clean is a must. I use a bottle brush to clean the main body of the feeder and an old toothbrush to get at the gook in holes and crevices.

Before you buy a hummingbird feeder, check out these features:

- Examine how the feeder comes apart. Will you be able to clean it easily, or will you have to work blindly in tight, hard-to-get-at crannies?
- Beware of feeders that require you to turn them upside down to remove and reinsert the reservoir; spilled sugar water is an annoyance on hands and clothes.
- Make sure your feeder has a decent-size reservoir that won't need refilling every day. Small feeders are cute but impractical.
- Avoid opaque feeders. You won't be able to tell if the inside needs cleaning.

Once you have chosen your feeder, you'll need to hang it up. I've found that a black iron shepherd's hook is a fine place to hang a feeder.

Continued

Plants That Attract Hummingbirds

You can grow a beautiful hummingbird garden by choosing a selection of the following plants. Or plant one or a mix in a hanging basket for head-high hummingbirds.

All grow well in full sun, with average soil, unless otherwise indicated.

Hardy Perennials

Bee balm (*Monarda didyma*)	Unusual whorled flowers in pink, red, white, and red-purple. Fast spreader. Zones 4 to 10.
Catmints (*Nepeta* spp.)	Loose, mounding clumps of silvery leaves with abundant, small, lavender-blue flowers. Most hardy in Zones 3 to 10.
Columbines (*Aquilegia* spp.)	Long-spurred flowers are held on bare stems above a rosette of pretty, lobed foliage. Most hardy in Zones 3 to 10.
Coral bells (*Heuchera sanguinea*, x *H. brizoides*)	Rosettes of scalloped leaves bear many long-blooming stems of tiny red, pink, or white blossoms. Go for the zingy colors to attract hummers. Zones 3 to 10.
Delphiniums (*Delphinium* spp.)	Beautiful spikes in all shades of blue, purple, and white rise above rosettes of foliage. Best in cooler climates. Zones 3 to 10.
Hyssops (*Agastache* spp.)	Densely packed, narrow spikes of tiny flowers, often with fragrant foliage, are more familiar to herb gardens but beloved by hummingbirds. Zones 4 to 10.
Penstemons (*Penstemon* spp.)	Midheight perennials with abundant tubular flowers in blue, white, and purple. Best in West. Many are difficult to grow and short-lived, but worth trying. Must have perfect drainage. Hardiness depends on species; varying from Zones 3 to 9.
Phlox (*Phlox paniculata*)	Old-time garden favorite with often fragrant flowers in pink, red, white, and lilac. Zones 3 to 9.
Pineapple sage (*Salvia elegans*)	Large bush with fragrant foliage and late-blooming, bright red flowers. Zones 8 to 10; grow as annual in cold regions.
Salvias (*Salvia* spp.)	*Salvia coccinea* (Zone 8, but grow as annual elsewhere) has brilliant red flowers. Red sage (*S. splendens*) cultivars are hummingbird magnets. Many are hardy in Zones 5 to 10, others only in Zone 9 or 10. Many of the tender salvias can be grown as annuals in all zones.

Annuals and Tender Perennials

Grow in a sunny spot, in well-drained average garden soil. Many will self-sow.

Cleome (*Cleome hassleriana*)	Spidery whorls in pink, white, and purple on 4' plants. Annual; all zones.
Four-o'clocks (*Mirabilis jalapa*)	Bushy, tuber-forming tender perennials with flowers in red, yellow, white, and pink—sometimes more than one color on a single plant! Blooms in late afternoon. Perennial in Zones 9 and 10; grow as annuals in all other zones.
Geraniums (*Pelargonium* x *hortorum*)	Familiar container plants with pink, salmon, red, or white flowers. Perennial in Zones 9 and 10; grow as annuals in all other zones.
Geraniums, scented (*Pelargonium* spp.)	A wonderful assortment of leaf shape and scent. Flowers are much less showy than common geraniums but highly attractive to hummers. Perennial in Zones 9 and 10; grow as annuals in all other zones.
Impatiens (*Impatiens walleriana*)	Indefatigable bedding annual with red, white, pink, lavender, and mixed colors. Perennial in Zones 9 and 10; grow as annuals in all other zones.
Nicotianas (*Nicotiana* spp.)	Sweet-smelling tobacco relatives with tubular blossoms. Avoid 'Nikki' hybrids. Nearly all are annuals. *N. alata* is a perennial hardy in Zones 9 and 10.
Petunias (*Petunia* spp. and hybrids)	Popular annuals with sprawling plants and a variety of colorful flaring trumpet flowers. All petunias will attract hummers. Annual; all zones.
Tithonia (*Tithonia rotundifolia*)	Huge, bushy but single-stemmed branching plant, to 8' high and 4' wide with a multitude of brilliant orange-red daisylike flowers in late summer. Also attracts butterflies galore. Annual; all zones.

Shrubs and Vines

Butterfly bush (*Buddleia davidii*)	Bush with fragrant, lilac-purple flowers held in conical spires at each branch tip. Zones 5 to 9.
Flowering quince (*Chaenomeles speciosa*)	Red, pink, or salmon flowers early in spring catch the first wave of migrating hummingbirds. Use dwarf cultivars such as 'Nana' in masses, as groundcovers; taller varieties are fine shrubs for mixed borders. Zones 5 to 10.
Fuchsias (*Fuchsia* spp.)	Earring-drop flowers in fabulous color combinations of red and purple, pink and white, and others. Grow as shrubs in warm climates; annuals elsewhere. Zones 8 to 10.
Mandevilla (*Mandevilla splendens*)	Hot pink tubular flowers on a tender vine that grows fast enough to be enjoyed as an annual. Zone 8 or 9.
Trumpetvine (*Campsis radicans*)	Fast-growing, extremely vigorous vine with rich orange tubular flowers. Give it a very sturdy support. May become a problem, but hummingbirds love it. Similar crossvine (*Bignonia capreolata*) is less aggressive. Zones 5 to 9.

insects—the foundation of the food chain, notes Neil Diboll, chairman of Prairie Nursery, Inc., in Westfield, Wisconsin.

"Insects are the number one food for baby birds, so plant the prairie plants, attract the bugs, and feed the birds!" says Neil. When you plant perennial wildflowers that attract insects, you're bound to attract the birds that dine on them. If you buy large plants, you'll get flowers the first year you plant. After the flowers are finished, sparrows, finches, and other songbirds will enjoy the seeds from fall right through winter.

Slip-Sliding Away

"I love squirrels," says Heidi Doss, "but sometimes they get into my birdhouses and destroy the nests." So Heidi made simple baffles for her birdhouse posts out of 30-inch lengths of PVC pipe. She slips the pipe over the post and lets it slide to the ground, then she mounts the house on top of the pipe. The squirrels can't get a climbing grip on the slippery plastic barrier.

"My wrens are much more relaxed," says Heidi, a teaching naturalist at Wesselman Woods Nature Preserve. "It's as if they know the squirrels won't be able to reach their eggs or babies."

Benefits of Bayberries

Bird lovers should try planting bayberry (*Myrica pensylvanica*), recommends Mike Hradel, owner of Coldstream Farm in Michigan. This easy-to-grow shrub not only offers evergreen shelter year-round, providing what Mike calls a "visual shield" to keep birds safe, but it also provides a winter banquet for birds. "It's unusual to find food and cover on the same bush in winter," he says.

Bayberry is tops with just about every bird that's around in winter. "More than 20 kinds of birds eat the berries," Mike notes, including pheasants, wild turkeys, flickers, downy woodpeckers, chickadees, Carolina wrens, and yellow-rumped warblers. "The one I could hardly believe is the tree swallow," he says. "I thought they ate only insects. But they love bayberries!"

The native shrub thrives in many soil conditions, including acid soils and poor, sterile, sandy soils, and is salt tolerant. Plant bayberry shrubs in full sun to partial shade in Zones 2 to 7.

The Cupboard Gourmet

Cleaning out the cupboards used to yield nothing more than a trash can full of stale food, so birdwatcher Deborah Burdick of Mount Vernon, Indiana, decided to make a special recipe for her backyard birds. "I emptied the last inch or two of all the cereal boxes, added some raisins that were hard as rocks, and mushed in the leftover oatmeal from breakfast," she relates. "Then I spooned out dabs of the stuff right onto the ground." Sparrows arrived before she even got back in the house, and they were soon joined by the local mockingbird and a bunch of noisy blue jays.

Now she crumbles stale crackers by hand so the pieces are smaller, and sometimes she treats her birds to a dollop of peanut butter for a tastier mix. Deborah says that natural cereals (without a lot of added sugar or preservatives) are best for the birds because they supply healthy calories that provide longer-lasting energy. Cereals with nuts or berries in the mix are always surefire favorites, too.

A Mix of Millets Suits Sparrows

Small seed-eaters like sparrows, juncos, buntings, and finches love the tiny, round seeds of millets, a group of annual grasses. Any type of millet is perfect for feeding birds from summer through winter because the birds pick every seed clean, says David A. Kester, owner of Kester's Wild Game Food Nurseries. Some millets shed their seeds and provide a banquet for sparrows and other ground-feeding birds. Other millets keep their seedheads intact on the plants, making sturdy landing pads for the finches who feed on the seeds.

David's company sells a millet mix that includes the familiar birdseed proso millet (*Panicum milliaceum*), which has an arching, branching seedhead that ripens in only 65 to 70 days. Siberian millet (*Setaria italica*), also called German millet, is another member of the mix. *S. berian* millet has interesting solid seedheads that "droop like a long finger," according to David. Seedheads like cattail pokers are the trademark of pearl millet (*Pennisetum glaucum*), another good bird plant. Japanese millet (*Echinochloa crusgalli*), with seedheads shaped like a turkey's foot, and several other types, round out the menu.

Plant a Food Patch for Birds

Tempt pheasants, quail, bobwhites, doves, and dozens of smaller birds with a patch of food plants just for them. David A. Kester, owner of Kester's Wild Game Food Nurseries in Omro, Wisconsin, encourages bird lovers to plant a special bird garden that includes both perennials and annuals. He recommends clovers, including bird's-foot trefoil (*Lotus corniculatus*), which sports clusters of sunny yellow blossoms, and bush clovers (*Lespedeza* spp.), which have small pink or purple pealike flowers. For fast payoff, include annuals like sorghum, buckwheat, and small-seeded soybeans and peas. Prepare a small planting bed, mix together a handful of seeds, and sow the seeds over the bed. Water generously until the seeds germinate, then take the low-maintenance approach—just wait for the bird visitors to arrive.

Some Like Their Gardens Wild

Find a discreet part of your garden and let it go wild, and you'll get all kinds of pleasant bird surprises, says Jim Becker, co-owner of Goodwin Creek Gardens in Williams, Oregon. Birds love weed seeds even better than birdseed. "Let some weeds stand, and you'll have birds visiting until every seed is gone," he says, pointing to chicory and wild lettuce as two favorites of feathered friends. Goldfinches are particularly fond of both plants, he adds.

Lamb's-quarters, dock, and ragweed (if you don't have allergies) are top-notch, too. Jim says that even a small patch of weeds (about 3 x 3 feet), will provide plenty of great edibles for feathered friends. If you have room, let an even larger patch go

Continued →

wild, and you'll be on your way to creating a natural bird habitat. Be sure to keep your wild patch well away from your vegetable garden, though, so that stray seeds don't sow a crop of heavy labor for next season.

Warm Water in Winter

Second-story condo resident and bird lover Elizabeth Castaldi of Washington, D.C., says supplying fresh water in the winter to birds is a challenge. On cold days, she fills a clay saucer with warm water in early morning. "The birds have learned my schedule," she says. "They're already in line for baths when I bring the water outside." When she heads to work, she brings the saucer indoors until the next morning's birdie bath time.

Plant a Birdseed Garden

When bird-feeder traffic drops off in late spring, Heidi Doss of Evansville, Indiana, has an ingenious solution for getting rid of the last few inches of birdseed. "I know whatever's left won't last until fall, when feeding season picks up again, so I use it to plant a garden for my birds." Heidi prepares a bed just as she would for planting annuals, then she scatters the leftover seed and covers it lightly with soil.

Plant mixed seed so that you can learn what kind of plants grow from birdseed. "Buckwheat really surprised me—I had no idea it was so pretty," says Heidi. Let the birdseed plants mature in place so that the birds can enjoy the seeds just as they grow. Birds will come and go in the patch all winter long, says Heidi.

Appreciating the Ordinary

Starlings, pigeons, and English sparrows were just "city birds" to Gretchen Harrison of Boston, but that changed when her two-year-old daughter, Erica, discovered the "birdies." Looking at the city bird life through fresh eyes, Gretchen found these birds as fascinating as any songbirds.

She and Erica feed their little troupe of feathered friends just what cosmopolitan birds like most—slices of sourdough bread, leftover French pastries, scraps of cream-cheese Danish, and the remnants of corned beef sandwiches. As the birds linger over the feast, Gretchen and her daughter learn their habits and personalities, and now they bird-watch daily on their sojourns through the city.

Once you change your outlook on city birds, you'll find they can be very interesting to watch. "Now I see how tender the pigeons are with their mates, and I love to watch the feathers on the starlings change colors in the sun, and listen to them sing," Gretchen says. "Even the English sparrows are pretty darn cute—especially if they're all you have!"

Wreath of Welcome

As soon as bird enthusiast Janice Ostock of Bethlehem, Pennsylvania, moved into her new home, she hung a grapevine wreath beside her front door. "I was still unpacking boxes when I noticed a house finch bringing sticks to the porch, and when I checked, I found a pair of them were making a nest in my wreath!" she exclaims. Since finches, robins, and other songbirds often nest near human haunts, wreaths and hanging baskets located near the doorway all make great nest sites.

Janice's birds built their deep cup-shaped nest on the bottom of the wreath. "It looked just like the wreaths you see in the shops," she says, "except instead of an artificial nest, mine was real—and had birds in it."

Birds Aren't Bread Snobs

If you're baking and things don't turn out quite right, put the "failures" out for the birds. Like Janice Ostock of Bethlehem, Pennsylvania, you may find that you end up baking just for the birds. When Janice experimented with her new electric bread maker, the first loaves were rejects, so she tossed them outside for the birds. "When I finally gave up on baking, I saw the birds were still coming for the leftovers—except there weren't any. I couldn't let them down, so I still bake—just for them! They aren't fussy at all about how the bread turns out," she says.

A loaf of her dense, chewy bread, chock-full of nuts and raisins, probably costs more than the day-old bread she could buy at a bakery outlet, but Janice says she doesn't mind. She likes baking for an appreciative audience who relishes even the mistakes.

View Vines As Opportunity

With their tangle of stems and often luxuriant leaves, vines are favorite hiding places and homesites for many songbirds. Learn to look in vines and you'll discover lots of bird nests, says Marie Bedics, whose Pennsylvania farmhouse has a wall covered with Boston ivy (*Parthenocissus tricuspidata*). The ivy shelters neighborhood wrens, sparrows, and robins at night, and its thick growth also provides a home for a catbird that has lived in her yard for well over a decade.

Other vines favored by birds include: Virginia creeper (*Parthenocissus quinquefolia*), English ivy (*Hedera helix*), autumn clematis (*Clematis terniflora*), anemone clematis (*Clematis montana*), and grapevines. All are excellent bird homes and hideouts.

Marie says the best part of the ivy-covered nests is that you never know there are any birds there. "But at night, just before dark, I can hear them twittering as they settle down to sleep," she says. "And I watch the catbirds coming and going with food for their babies."

Keep the Neighbors Happy

Natural-looking gardens make birds and butterflies happy, but they may stir up trouble in a neighborhood of traditionally groomed lawns. Jean Hadley, whose natural landscape covers acres in Solitude, Indiana, suggests a couple of simple tricks to keep neighbors content. "That feeling of the yard being out of control seems to be what bothers neighbors most," she says. "If

you're making the transition from grass to plants in your yard, make sure you have nice, neat, wide paths going through it. That gives it a planned look that signals the plantings are intentional and not just noxious weeds left to roam."

Jean says that a fence helps too—not to hide the gardens, but just to give them a civilized feel. A jumble of plants along a split-rail fence looks a lot better to most people than a so-called weed patch, she says. Even though you could have the same plants with either scenario, adding the fence can make a huge difference in how the garden is perceived.

Winter Fruit for Wild Birds

Most trees drop their fruit in fall, says Mike Hradel, owner of Coldstream Farm in Free Soil, Michigan, when there's more than the birds can eat. But in winter, when they really need it, there's little available. Good bird plants for wintertime, he suggests, are dogwoods and crabapples; he also recommends small-fruited crabapples like 'Sargent' and 'Zumi,' which bear perfectly bite-size fruit for avian visitors.

Paint Is for People

"Birds would much rather be in a birdhouse that's made as inconspicuous as it could be," says David H. Drake, president of Coveside Conservation Products in Maine. "Otherwise it's easier for predators to find them." He recommends leaving nesting boxes au naturel, with no paint or decorations, so that they blend in with the landscape as easily as tree bark.

A coat of paint won't deter birds, but David adds, "Paint is for people—the birds don't care!" Sometimes paint can be a good thing, he says. If your spring weather swings from warm to cold, a dark-painted birdhouse will soak up heat and keep it cozy. If you put a birdhouse in full sun, a coat of white paint will keep it cooler inside by reflecting those warming rays.

Best Bets for Nest Building

Indian hemp (*Apocynum cannabinum*) and the very similar-looking dogbane (*A. androsaemifolium*) supply perfect nest-building materials for orioles and vireos, says Jean Hadley of Solitude, Indiana. Colonies of these plants grow at the wood's edge and in the meadow on Jean's property. All winter long, the stems of the plants weather in the rain and snow to become bird magnets by late spring. That's when Baltimore orioles, vireos, and the occasional yellow warbler descend to pull apart the old stems, stripping off thin, soft strings that are as tough as dental floss—just the thing for weaving nests. Plant dogbane and Indian hemp where the plants have room to spread naturally into a colony.

Get Wild with "Wild Ones"

If joining together with other nature lovers for seed exchanges, chats with kindred spirits, nature hikes, field trips, excursions, and tours of backyard wildlife gardens sounds like your cup of tea, get in touch with Wild Ones—Natural Landscapers, Ltd., a nonprofit group dedicated to educating and sharing information among "regular people" who love to learn about wildlife.

Members share information about gardening with native plants, attracting birds to their gardens and flower beds, and generally creating wildlife-friendly, ecologically sound backyards. For more information, write to Wild Ones 2285 Butte des Morts Beach Road, Neenah, WI 54956-1008.

Keep the Peanut Eaters Happy

Peanuts are a big draw for woodpeckers, blue jays, chickadees, titmice, and nuthatches, but the nuts disappear fast when you offer them in an open feeder. The perfect solution is a tube feeder of stainless-steel wire mesh with ¼-inch holes, says Betsy Colwell, president of Droll Yankees. The mesh holes are too small to let birds grab whole peanuts, but plenty big for woodpeckers and others to hammer through and get pieces.

The big draw for the peanut feeder is the woodpeckers, says Betsy. "They love peanuts! They'll bang away, just like they do on trees." Squirrels don't bother the feeder, she says, because they can't chew through the mesh.

If you're the handy type, you can make a homemade peanut feeder by replacing the plastic tube of an existing tube feeder. Here's how:

1. Measure the circumference and height of the tube of the existing feeder. (For example, some tubes measure 11 inches around and 12 inches high.) Buy a piece of stainless-steel, ¼-inch wire mesh to correspond to the measurements you took. If you can't find stainless steel mesh, use hardware cloth.
2. Roll the wire mesh into a tube shape to fit the feeder's top and bottom, then bend the mesh over itself to anchor the edges together.
3. Fasten the feeder top and bottom to the mesh. Usually, the bottom of the feeder will hold tight when inserted into the mesh, and the top is held in place with the wire hooks at the ends of the handle.
4. Insert the bottommost perch of the feeder.
5. Fill with shelled whole peanuts, and hang the feeder in a spot where you can watch the visiting birds.

Faking It

Many gardeners use red flowers to lure hummingbirds to their garden, where they'll stay to sample flowers of other colors, too, but natural-garden lover Jean Hadley of Solitude, Indiana, had trouble fitting fire-engine red into her romantic pastel color scheme. So she turned to subterfuge—a quick trip to the local discount store gave her an armload of red silk flowers that she wired to nearly everything in the garden. "It worked like a charm!" says Jean laughing.

Continued →

Now she has hummingbirds every summer, returnees who remember her garden of nectar-filled flowers, even though the red silk deception is long gone.

Shape Is What Matters

If you love hummingbirds, plant a garden specifically for them. Jim Becker, co-owner of Goodwin Creek Gardens, says flower shape, not color, is what matters most when planning a hummingbird garden. Tubular flowers, whether they're tiny mint flowers or 8-inch datura blossoms, are what hummingbirds seek. Their long, skinny beaks are exactly right for reaching the nectarines at the base of these flowers. "Red gets their attention, but they really like deep purples and blues, too," he notes.

Hummingbirds will go to just about any flower, Jim says. If it proves to be a good nectar source, they'll return to it over and over. One of Jim's favorite hummingbird flowers is a white-flowered selection of normally bright red cardinal flower (*Lobelia cardinalis*), which he selected from a batch of seed-grown plants.

Natural Nectar

Hummingbirds are hungry after migratory flights, so treat them to nectar-rich early bloomers. Jim Becker suggests planting red flowering currant (*Ribes sanguineum*), a graceful shrub or small tree native to the Pacific Northwest that's also at home in Zones 6 through 8. A buffet table in a bush, dangling clusters of red-to-pink fragrant flowers decorate the branches very early in spring.

High-Rise Hummingbirds

Hummingbirds have such an eye for red that they'll go to great lengths—or heights—to investigate, says Elizabeth Castaldi of Washington, D.C. Trying to brighten her small second-story balcony, she added a pot of bright red zonal geraniums (*Pelargonium* spp.) that could take the all-day sun and heat. Within days, she noticed a male ruby-throated hummingbird at the flowers. When migration time came in early fall, she had a constant stream of tiny winged visitors humming with delight at her bright container garden.

Bring on the Hummers

"Hummingbirds return from migration in early spring, when there's not a lot blooming in the garden," says Jim Becker, who co-owns Goodwin Creek Gardens with his wife, Dottie. Luckily, the long-spurred, nectar-filled blooms of native American columbines are just hitting full stride when the zippy little birds return to the scene. Jim and Dottie grow both the eastern and western wild columbine (*Aquilegia canadensis, A. formosa*). Both are great garden plants as well as hummingbird plants. Columbines bloom for weeks, sustaining the birds until other plants come into flower.

Advantages of Agastaches

Their Latin name may be a mouthful, but perennials from the genus *Agastache* are sure-fire hummingbird attractors. Most plants have foliage with a delicious licorice scent, which has given more than one species the nickname licorice plant, or anise hyssop. But it's the whorled spikes of small tubular flowers that are the prime attraction for hummingbirds.

Many gardeners are familiar with anise hyssop (*Agastache foeniculum*), but there are many more to be discovered, says Jim Becker. Native mostly to the American Southwest and Mexico, agastaches include many plants of surprising cold hardiness, usually to Zone 6.

Agastache species and hybrids offer a variety of flower color, including blue-purple, salmon, rosy orange, pink, and pale blue. Hummingbirds love all of them. Jim recommends 'Apricot Sunrise,' whose beautiful orangey apricot flowers light up perennial gardens. 'Firebird' is a vivid orange-salmon-flowered hybrid that creates a full, branching plant.

Richly fragrant rock anise hyssop (*Agastache rupestris*) has gray-green foliage and rich, rosy orange flowers; hardy to Zone 5, it blooms for almost two months straight. Plant in lean, well-drained soil in full sun.

Perch-Free Means Predator-Free

Perches on birdhouses are so common that it doesn't occur to most people that perches allow predators access to baby birds. If you're building new birdhouses, eliminate the predator threat by skipping the perches, or saw off the perches from an existing birdhouse, says David H. Drake, president of Coveside Conservation Products.

If you think about it, natural nesting cavities don't come with perches—nearby twigs and branches serve as landing platforms for arriving bird parents. Birdhouse perches offer raccoons or cats a balancing spot and allow them to reach an exploring paw inside the nest box, which often proves fatal to young nestlings.

Help Birds Get a Grip

Rough-sawed boards are cheaper than finished lumber and better for birdhouses, says David H. Drake. Rough-sawed boards make it easy for little bird feet to get a grip on the roof, sides, or front of the house.

Handy Hinges Make Cleaning Easier

Cleaning out a birdhouse is easy if the house has a hinged side or front, says David H. Drake. On birdhouses with hinged openings, you'll need to undo the fastener, open the side, and make one swipe with your rubber-gloved hand to neaten things for the next resident. If you decide to clean out old nesting materials, it may be best to wait until the beginning of the breeding season to allow time for beneficial wasps to emerge from hibernation in the old nest. Wasps help control parasitic blowfly populations that can lower the survival rate of nestlings.

Annual Flowers for the Birds

These annuals produce seeds that birds like to eat. All of these flowers thrive in full sun, so choose an open spot for your bird-garden planting.

Sweet alyssum (*Lobularia maritima*)

Pink, purple, or white blooms appear in ¾-inch-wide clusters on 6- to 12-inch-tall mounds of foliage

Grain amaranth (*Amaranthus hypochondriacus*)

Spiked flower heads grow 1 foot tall and are red, green, or marbled red and green; the seed heads are beautiful; plants grow 6 feet tall

China aster (*Callistephus chinensis*)

Blue, rose, or white blooms are 2½ inches wide; plants grow 2 feet tall.

Bachelor's buttons (*Centaurea cyanus*)

Blue, pink, purple, red, or white blooms grow 1 to 2 inches wide on 12- to 30-inch-tall plants

Black-eyed Susan (*Rudbeckia hirta*)

Daisylike yellow blooms have brown centers and grow 2 to 3 inches wide; plants grow 1 to 3 feet tall

Cosmos (*Cosmos bipinnatus* and *C. sulphureus*)

Blooms are 1 to 2 inches wide; *C. bipinnatus* has pink, white, or crimson ray flowers with a yellow center; plants grow 4 to 6 feet tall; *C. sulphureus* has yellow, red, or orange daisylike blooms on 2- to 3-foot-long stems

Flax (*Linum usitatissimum*)

Blue or white delicate ½-inch-wide blooms grow on 3- to 4-foot-tall stems

Larkspur (*Consolida orientalis*)

Blue, rose, violet, or white blooms are 1½ inches long and grow on long spikes; plants grow 1 to 2 feet tall

Pincushion flower (*Scabiosa atropurpurea*)

Rounded 2-inch-wide blooms come in blue, cream, lavender, maroon, pink, and white; plants grow 2 to 3 feet tall

Corn poppy, Shirley poppy (*Papaver rhoeas*)

Four-petaled 2-inch-wide blooms come in deep purple, red, or white; plants grow 2 to 3 feet tall

Sunflower (*Helianthus annuus*)

Yellow, red, and rust-colored blooms grow 3 to 12 inches wide on plants that are 1 to 12 feet tall (size depends on the variety)

Squirrel-Proofing Your Birdhouses

You may have visions of happy bird families when you mount that new birdhouse, but your neighborhood squirrels have other plans. Rambunctious squirrels often gnaw the entrance holes to enlarge them so the squirrels can move in instead of the birds. You can squirrel-proof nest boxes with a slate or metal barrier to keep out the varmints, says David H. Drake, president of Coveside Conservation Products, makers of high-quality wooden birdhouses fitted with antisquirrel devices. The guards are easy to cut and install, although you may find it easier to have a masonry or metal shop make them.

You will need a square of slate or sheet metal twice the size of the birdhouse's entrance hole. For example, if the entrance hole measures 2¼ inches in diameter, the slate or metal should be 4½ inches square. Drill a hole the same size as the entrance hole in the corner of the slate or metal square, using a masonry drill bit if drilling through slate. Place the guard flush with the front of the birdhouse, aligning the holes. Drill into the wood along the outer edges of the guard, then attach it to the birdhouse, using the heads of the screws to anchor the guard in place.

Let the Sun Shine In

The latest bird-behavior research shows that house sparrows prefer a dark home to a light-filled one, so you can discourage them from monopolizing your birdhouses by retrofitting your existing houses to allow light in through the roof, says David H. Drake, president of Coveside Conservation Products.

You can test the theory in your own backyard by making a few quick changes to your existing bird boxes, but be sure to use this method only on boxes that are placed in shaded areas so that the interior temperatures of the boxes don't soar when the sun pours in.

To discourage house sparrows, there are two methods that allow the sun to shine in, yet keep predators out. The method (Steps 1–3) uses heavy-duty wire mesh and is the easiest to install, but it doesn't offer the birds any protection from the rain.

The method works for flat-roof and sloped-roof houses.

1. Remove the roof from the existing house.
2. Using wire cutters, cut a piece of ¼-inch or ½-inch wire mesh (as heavy-duty as possible) 1 inch wider than the inside diameter of the top of your birdhouse.

Continued →

3. Bend the sides of the mesh up so that the mesh fits snugly within the width of the birdhouse. Using a staple gun and staples, staple the mesh securely to the inside of the house about 2 inches from the top edge. The mesh will let in sunlight but keep out predators.

The Magic of Running Water

"I've read that birds are attracted to the sound of running water," says Heidi Doss of Evansville, Indiana, "but I'm a long way from the closest creek." So when Heidi found a small, battery-operated submersible pump for $20 at her local home-supply store, she set it right in her birdbath amongst the river stones. "I get to see all kinds of birds coming to drink—orioles, tanagers, warblers, vireos, plus the usual robins and catbirds—and I get to soak up that wonderful soothing sound," she says. She keeps her pump on the lowest setting so there's only a gentle gurgle through the outlet pipe, just enough to make the sound of water music.

Poke Your Perspective

Pokeberries aren't people-friendly—they're poisonous—but birds devour them with great enjoyment. Mockingbirds, robins, thrashers, waxwings, thrushes, downy woodpeckers, flickers, and many others flock to pokeberries. "A lot of people think of poke as a weedy thing," says Jim Becker, co-owner of Goodwin Creek Gardens, but when a photograph of pokeweed (*Phytolacca americana*) and artemisias in a garden setting appeared in a national magazine, he noted that interest in the plant surged. "In the right setting it can be very pretty—those big, tall, arching reddish purple stems and the purple fruits in fall."

Sometimes more unusual bird visitors show up. Jim notes he got a good look at a pileated woodpecker on his poke plant. The almost crow-size bird was hanging upside down to eat the fruit.

Grasses for Bird Safety

Thick-growing prairie grasses or other ornamental grasses planted here and there in the landscape provide a safe haven for birds that need to make a quick dash to safety. They grow fast, too, making them useful from the first season they're in the soil. And most stay useful over winter, offering birds a tangle of sheltering stems, not to mention a bounty of nutritious seeds and nesting material in the spring. Neil Diboll, chairman of Prairie Nursery, Inc., in Westfield, Wisconsin, says that prairie grasses can play a starring role in a wildlife-friendly garden. "The plants of the prairie have the unique ability to combine both habitat and beauty," he says. Try these easy-to-grow prairie grasses: big bluestem (*Andropogon gerardii*), switchgrass (*Panicum virgatum*), and Indian grass (*Sorghastrum nutans*).

"Orange" You Fond of Hummingbirds?

This simple formula lures hordes of hummingbirds—especially Anna's and black-chinned types—to Charity Hagen's yard in Wildomar, California. "If you want to *really* attract a lot of hummingbirds," Charity says, "add orange extract to the hummingbird nectar." She explains that you can buy orange extract at the grocery store or just squeeze orange juice into the hummingbird feed mixture.

Ingredients and Supplies

1 part sugar

3 parts water

A few drops of orange extract or orange juice

Directions

1. Dissolve the sugar in the water.
2. Add the orange extract or orange juice and stir a few times. (Don't add red food coloring, since it's bad for the birds' health.)
3. Pour the mix into a hummingbird feeder, or store it in the refrigerator for up to 2 weeks.

Note: You probably won't have to worry about leftover nectar, since, according to Charity, "it keeps the hummingbirds coming back for more—they just can't resist it, and the orioles love it too!" But if any mix remains in the feeder after a week, discard it and replace it with fresh formula. Wash out the feeder before adding the fresh mix.

Birdsong Granola

This recipe is a "natural" for health-conscious birds! "I always make granola for my family," explains Diane Winslow, an avid birder and the owner of It's About Thyme herb nursery in Austin, Texas. "And as I read about what nutrients birds need, it seemed like a granola-like mix would be good for them, too." Your birds will love it!

Ingredients and Supplies

1 cup corn oil or peanut oil

1 cup honey

2 cups chopped nuts

2 cups millet

1 cup wheat germ

2 cups raisins or other dried fruit, except coconut

2 cups hulled sunflower seeds

2 cups crumbled dog biscuits

Directions

1. Mix the oil and honey, then heat gently just until they blend together.
2. Mix the other ingredients in a large bowl. Add the warm honey and oil, and stir to combine.
3. Press the mix into a shallow baking pan.

4. Bake at 375°F for 10 minutes.

5. Let cool, then crumble and serve to birds.

Yield: 11 cups of granola

Variations: You can use this recipe as a starting point, then add other ingredients as they become available. Diane adds crumbs from bread, cake, or crackers. "You can use any dried fruit except coconut, which swells in the bird's stomach," Diane cautions. In the winter, combine the granola with suet to supply the extra fat birds need to keep warm.

SERVING SUGGESTIONS

Scatter some Birdsong Granola on the ground and birds will come. But for a really good response from your feathered friends, follow the example of Charity Hagen of Wildomar, California. Charity says that the key to attracting lots of birds is the placement of the feeders.

To attract the greatest variety of birds, place your feeders at different sites and arrange them at different heights. Place several feeding trays or platforms on the ground, then set up one or two feeders a few inches above ground level. Arrange some feeders a foot or two off the ground, and hang other feeders higher up in trees. (Place the ground feeders in an open area away from bushes and plants so that predators can't sneak up on the birds.)

When you use multiple feeding stations, you give ground-feeding birds all the room they need to eat in comfort. And by adding feeders at several different heights, you provide feeding options for birds that are too shy to feed directly on the ground.

Christmas Cookies for the Birds

This Christmas, decorate the leafless trees around your home, not with lights and tinsel, but with suet cakes cut into festive shapes. That's how Barbara Lucich of Pleasanton, California, and her siblings decorate around their mother's home for the holidays.

Ingredients and Supplies

Cookie cutters
Waxed paper
1 cup lard
1 cup crunchy peanut butter
2 cups rolled oats
2 cups cornmeal
1 cup flour
½ cup sugar
Makeshift hole puncher, such as a chopstick, skewer, or awl
Ribbon or yarn

Directions

1. Place the cookie cutters on a tray covered with waxed paper.
2. Melt the lard and peanut butter in a saucepan at low heat. Add the remaining ingredients and stir well to form a thick mixture.
3. Pour or spoon the mix into the cookie cutters to a depth of about 1 inch.
4. Poke a hole in the suet near the top of each cutter. Make the hole large enough to thread ribbon or yarn through.
5. Put the tray of filled cookie cutters into the freezer for at least 1 week.
6. Remove the cookies from the cutters and peel off the waxed paper. Thread ribbon or yarn through each and hang them outside.

Yield: Approximately 8 cookies

Suet Smorgasbord

Bird enthusiast Robin Guy feeds birds all year long at her home in Lake Forest, Illinois. The birds appreciate her offerings in spring, summer, and fall, but particularly enjoy a special treat she cooks up for them when cold winds blow. "In winter, once we've had a few hard freezes, we give the birds some extra fat in their feed in the form of suet," she says. Cherries and seeds make this mix particularly palatable to birds.

Ingredients and Supplies

1–1½ pounds beef fat
¼ cup millet (red and white mixed, if possible)
⅓ cup cracked corn
⅛–¼ cup safflower seeds
¾ cup chopped dried cherries
Small containers, like plastic margarine or cottage cheese tubs
Waxed paper

Directions

1. Warm the beef fat in a saucepan until it melts. Pour off the liquid as the fat melts to prevent it from burning.
2. Let the liquid fat cool slightly, then stir in the other ingredients. Robin notes, "All measurements are approximate. I never measure—I just add whatever is needed to make it look right!" It looks right, Robin says, when the seeds and fruit are almost touching each other, with the fat acting as a binder.
3. Line the containers with waxed paper and pour in the mix.
4. Refrigerate until cool, then store in the freezer until ready for use. You can put a suet cake out for the birds without thawing it.

Continued ➔

Pop a suet cake out of its container and hang it in a mesh bag or wire suet cage.

Yield: About 4 cups of suet

Variation: Cracked Corn Suet

Increase cracked corn to 1 cup. Replace cherries with ¼ cup black oil sunflower seeds.

Variation: Sunflower Suet

Decrease cracked corn to ¼ cup. Replace cherries with 1 cup black oil sunflower seeds.

FREE INGREDIENTS FOR YOUR SUET SMORGASBORD

You can get fruit and fat for suet mixes without spending a dime! Robin Guy gets the fruit for cherry suet from her cherry trees. She collects imperfect cherries with insect holes or bird damage, cuts up the fruit in halves or quarters, and dries them in her dehydrator. Then Robin stores the dried cherries in the freezer until winter when she makes suet. If you eat meat, follow Robin's example and cut the beef fat from your steaks. Freeze it in labeled packages until you're ready to make suet. Otherwise, you can get fat inexpensively or free from a butcher.

Beat-the-Heat Bird Treat

It's a challenge finding suet-type bird feeds that don't melt down in hot climates. Just ask Paul Reinartz, a gardener and bird lover from Austin, Texas. When his suet mixes became rancid thanks to hot Texas temperatures, Paul started looking for alternatives. He found a way to beat the heat when his sister-in-law shared this peanut-butter-based recipe with him.

Ingredients and Supplies

- 1½ cups water
- 1 cup uncooked oatmeal
- ¾ cup lard or bacon grease, melted
- 1 cup Cream of Wheat or Wheatena
- 1 cup hominy grits or corn meal
- ½ cup raisins or dried currants
- 1½ cups creamy peanut butter (chunky is acceptable if that's all you have)
- 2 handfuls birdseed or chicken scratch
- Waxed paper
- Zipper-closing plastic storage bag

Directions

1. Bring the water to a boil and add the oatmeal. Turn down the heat and let simmer for 1 minute.
2. Remove the oatmeal from the heat and stir in the remaining ingredients in the order listed above.
3. When the mixture is cool enough to handle—without sticking to your hands like glue—mold it into round cakes that are about the size of a tennis ball (2½ to 3 inches in diameter).
4. Set aside any cakes that you plan to use immediately. Place the rest on a waxed-paper-lined cookie sheet and put them in the freezer.
5. When the cakes are frozen, store them in a plastic storage bag in the freezer.
6. When you're ready to serve a cake to the birds, let it thaw until it's soft. Then you can set the cake in a birdfeeder, hang it in a mesh bag, or press it onto the surface of a pine cone. Paul recommends placing the cakes in a shaded area so they'll keep longer.

Yield: 6 to 8 cakes

A SAMPLING OF SUET-LOVERS

Birds large and small love suet. When you hang suet treats in your yard, you may have bird visitors ranging from wily woodpeckers to cheerful chickadees. Titmice, mockingbirds, and jays belong to the suet-loving crowd, too.

Gardeners in the Southeast and Texas who put out Beat-the-Heat Bird Treats may spot downy and red-bellied woodpeckers, white-breasted and brown-headed nuthatches, Carolina chickadees, blue jays, and summer tanagers enjoying the suety mixture.

CATER TO SMALL BIRDS WITH A COCONUT FEEDER

To keep large birds from eating his peanut butter suet cakes, Paul Reinartz devised this coconut feeder. Small birds, like chickadees, can light on it, but larger birds set it rocking.

You'll need one small coconut that is about 5 inches in diameter, one small piece of scrap wood about the size of a thumbnail (about ¾ inch square and thick), and one small eye hook. You'll also need one dowel rod that's about the diameter of a pencil and about 8 inches long—the length depends on the size of the coconut.

Step 1. Use a fine-bladed saw, like a hacksaw or keyhole saw, to cut a round hole about 2½"-3" in diameter in the top of a coconut—the end that has indentations. (Paul cautions that coconuts crack easily, so handle them gently.) Then scrape out the contents of the coconut.

Step 2. Balance the coconut on the tip of a pencil inserted through the hole. When you find the spot where the pencil must rest to balance the coconut, mark the location of the pencil tip on the outside of the shell. Carefully drill a hole in the top of the coconut using a small drill bit. Move the bit around so that the hole is bigger than the threaded end of the eye hook.

Step 3. Drill a hole in the center of a small piece of scrap wood. Then place the scrap wood inside the top of the coconut,

aligning the drilled holes. Put the eye hook through the coconut and thread it into the wood.

Step 4. Cut a notch in the bottom of the large opening, then glue a dowel to the back of the coconut and into the notch. Pack a softened peanut butter suet cake into the back of a coconut feeder and hang the feeder from a tree.

Blooms for the Birds

Are you too busy to fill the bird feeder? With this mix of plants, you can still feed the birds all summer. That's because the plants all have bird-attracting seeds. "Because these are annual plants, you can grow them in any region," explains horticulturist Linda Harris of Ferry-Morse Seeds.

Ingredients and Supplies

Metal garden rake
1 seed packet sweet alyssum
1 seed packet grain amaranth
1 seed packet China aster
1 seed packet bachelor's buttons
1 seed packet black-eyed Susan
1 seed packet cosmos
1 seed packet flax
1 seed packet pincushion flower
1 seed packet corn poppy or Shirley poppy
1 seed packet sunflower

Directions

1. Prepare the site by digging or tilling to loosen the soil if needed.
2. Scratch the soil surface about 1 inch deep with a metal garden rake. Then use the back of the rake to smooth the soil.
3. After your area's last spring frost date, mix the seeds together. Each seed packet contains about 100 seeds, which will cover a bed that's about 10 x 20 feet (200 square feet). You may need to combine only a portion of the seed in each packet. You can save the leftover seed or share it with your friends.
4. Broadcast the seed over the bed by hand. You may want to add some sand or potting soil to the seeds first to make the mix easier to distribute evenly.
5. Press the seed into the soil surface by walking gently on the bed or by dragging a board over the bed.
6. Keep the seeds moist until the seedlings are about 2 inches tall.

Note: Linda points out that most of the plants will reseed, so you don't have to replant every year. But if you want to make sure that a particular flower always appears, scatter more of those seeds over your planting area each spring.

Setting the Table for Birds

Just like relatives, birds and other wild creatures will beat a path to your garden if they can find a free meal there. Many songbirds love sunflower and other seeds, while woodpeckers and nuthatches prefer a high-fat diet of nuts and suet. Several of the showiest birds prefer fruit. To attract the widest variety of birds, provide special feeders stocked with different foods in different parts of your yard. In addition to the fruit feeder, you can make a "Goldfinch-Getter" tube feeder, turn a fruit box into a tray feeder, or make a stone landing trimmed with fragrant herbs for the area where you offer tempting seeds.

If you're just getting started feeding birds and other wildlife, do a little research to see who's likely to visit, and at what time of year. Check with your neighbors or your local cooperative extension office to get the scoop on the birds and other critters that live in or migrate through your area. Then set the table accordingly, putting out only a little food at first, so there's less wasted if it goes uneaten. When you start to get takers, increase the supply to match the demand. With a little patience, you'll be amazed at the variety of wildlife that shows up looking for breakfast in your yard. Different species may show up at dusk for an early dinner.

SITE YOUR BIRD GARDEN RIGHT

This planting has a very informal, wildflower-meadow look, according to Linda Harris, so choose a site that's not too close to the house but still close enough to enjoy. To make the planting look less wild and more gardenlike, she suggests growing three different sunflower varieties of different heights. The similar flowers will help tie the planting together for a more coordinated look.

Make a Cagey Fruit and Suet Feeder

Barbara Pleasant

Serving fruit to tempt orioles, mockingbirds, catbirds, house finches, Carolina wrens, thrashers, and other fruit-loving birds is as easy as impaling an orange half on a sturdy nail and waiting to see who flies in for a sweet meal. Unfortunately, the birds may lose out on this treat when squirrels, raccoons, and other varmints discover that they can make off with the fruit. Capable

Continued ➔

of doing double duty as a box for purchased suet cakes, this simple feeder lets birds enjoy halves of oranges or apples while deterring greedy starlings, raccoons, and squirrels.

You Will Need

Tools: Measuring tape, pencil, saw, drill with ¼-inch bit, wire cutters, hammer, screwdriver

One 22-inch-long piece of 1 x 2 furring strip

1 wire clothes hanger

Eight 2-inch nails

1 scrap board or shingle, 8 to 12 inches long and 6 to 8 inches wide

One 6-inch-square piece of wire hardware cloth with ½-inch mesh

One 2-inch-long piece of thin scrap wood or wood craft stick

One 3-inch nail

2 screws

1. Saw the furring strip into two 6-inch pieces and two 5-inch pieces. Lay them on a flat surface to form a square frame. Use the drill to make matching holes through the lower sides of the frame 1 inch from the bottom of the side pieces. Use the wire cutters to cut the straight bottom from the clothes hanger, and check to see that it easily passes through the drilled holes in the sides. Set the hanger wire aside.
2. Use 6 of the 2-inch nails to nail the frame pieces into a square on the scrap board or shingle base.
3. Cut a square of hardware cloth to match the size of the frame. Weave the hanger wire through the bottom of the hardware cloth, and then push the ends through the holes in the sides of the frame. Use wire cutters to bend them back toward the base.
4. Turn the feeder over, and drive a 2-inch nail through the back of the baseboard, so that its tip protrudes through the center of the wooden frame.
5. Loosely nail the 2-inch-long piece of scrap wood or craft stick to the top of the frame to hold the hardware cloth door closed. Drive a 3-inch nail into the base of the frame to serve as a perch.
6. Drill guide holes for the mounting screws, and securely attach the feeder to a sturdy post or dead tree. Stick it with a halved apple, orange, or a cake of suet.

Make an "Oh My Darling" Tray Feeder

Barbara Pleasant

Providing meals for birds and other wildlife doesn't have to be a budget-buster—and your wild guests won't groan "not this again" like your family does when they find leftovers on the table. Foods such as bread or pizza crusts, crushed crackers, leftover pasta, fruit pieces, and crumbled suet work best when offered on a tray feeder's flat feeding surface. In addition, these freebies can help to draw bossy crows, jays, magpies, pigeons, and starlings away from your seed feeders, reducing your seed bill and giving your favorite songbirds a chance to enjoy their preferred foods in peace.

Tray feeders are a handy way to offer all sorts of foods that don't lend themselves to other types of feeders, so they're the perfect place to serve bird-friendly leftovers. A tray with a wire mesh bottom will let some crumbs sift through, but it also lets water drain away, so foods on the tray don't get soggy (and moldy) if they sit for a couple of days. Even so, keep an eye on treats that you put on your tray feeder. If birds don't gobble them up in a day or two, empty the tray and try offering your feathered friends something else.

Making a tray feeder is easy. Treat yourself to a box of the sweet little oranges known as clementines, and then transform the lightweight wooden box into a feeder. If you don't have a fruit box, use an old picture frame with its back removed as a tray feeder frame.

You Will Need

Tools: Tin snips, staple gun, drill

One 24-inch-square piece of aluminum screening

1 open-topped fruit box

4 small screw eyes

4 yards of nylon cord or lightweight chain

One 12- to 18-inch piece of wire

1 S hook

1. Cut a piece of aluminum screening to match the outside dimensions of your wooden box. Staple the aluminum screening to the bottom of the box to keep feeder foods from falling through the cracks and corner holes.
2. Drill a small pilot hole at each corner of the top (open side) of the box and insert a screw eye in each hole. Fasten a piece of cord to each screw eye. Join the other ends at the top, so the feeder hangs parallel to the ground.
3. Loop the wire over a tree limb, fasten the ends securely, and use the S hook to attach the feeder to the wire.

Wildlife That Preys on Insect Pests

Beneficial insects and birds aren't the only kinds of beneficial animals. Several other kinds of wildlife are predators of pest insects or problem rodents. Take a few simple steps to attract and assist these helpers.

Bats. The common brown bat can eat 3,000 insects (including lots of mosquitoes) in one night. You can build houses especially for bats to roost in. They're also attracted by ponds.

Lizards and salamanders. These creatures eat vast numbers of insects and do no harm to anyone. They're attracted by cool, damp places like rock piles.

Snakes. Dangerous snakes are rare—there are only four species in the United States—and not likely to visit the garden. The ones you see control rodents, insects, even slugs and snails! Snakes like the shelter of rocks, woodpiles, or brush near the garden.

Toads and frogs. Just one toad can consume well over 10,000 insects (slugs too!) in one year. Make a cool, dark toad shelter out of rocks or inverted clay pots that have "doors" chipped out.

Moles. Even these maligned marauders of spring lawns have a garden benefit. Moles eat huge numbers of grubs, like Japanese beetle grubs. They even cultivate parts of my garden but have moved on to deeper or damper locations by planting time! So before you act to "get rid of" any of nature's living gifts, consider the big picture—how everything relates to everything else. Maybe you'll find you have lots more friends than you knew!

A Place for Snakes

Sally Jean Cunningham

When I find rocks in my garden beds, I stack them in piles and leave them there. Rock piles help to welcome and shelter toads and lizards, as well as some other pest eaters that have a bad reputation—snakes! Snakes give many people the creeps. But most snakes are not poisonous. And they aren't slimy or sneaky or interested in you at all. (Where I live in western New York, virtually no snakes are dangerous—certainly *not* the ones we see around our gardens.)

I was lucky to learn as a child that snakes are great to have around. My grandpa Harper taught me how to pick up snakes behind the head and showed me that they are dry and cool to the touch—and very interesting. I've taught my daughter, Alice, about snakes too.

Country homes need snakes to control rodents in outbuildings and basements. Snakes are very valuable around the garden, where they eat insects as well as rodents. Snakes like the shelter of rock piles, brush piles, woodpiles, and sometimes black plastic or boards, so I purposely set up a few such snake-friendly locations around the garden.

Pave the Way to Bird-Feeding Ease

Barbara Pleasant

The favorite food of seed-eating birds, sunflower seeds meet with less approval from lawn-lovers trying to tend the turf below the feeder. In places where birds dine and sunflower shells fall, sparse grass and anemic flowers are a common result, because sunflower shells—and constant bird pecking—inhibit the growth of other plants. Paving the area beneath a seed feeder solves the problem and makes feeder maintenance easier, too. Your paved feeding station will serve as a beautiful landscape focal point even when no birds are present.

Installing pavers involves a bit of heavy lifting, but it's an otherwise easy project that produces long-lasting results. Doing the math to figure out how many flagstones or pavers you need is simple multiplication, but you may get confused when estimating how much paver base and sand to buy. These materials are sold in 40- to 60-pound bags, which contain a specified measurement in cubic feet (this information is printed on the label). One cubic foot is 12 inches wide and deep, so a cubic foot of crushed stone will cover 6 square feet when spread 2 inches deep (12 divided by 2 equals 6).

You Will Need

Tools: Stakes and string, shovel, wheelbarrow, tamping tool, carpenter's level, mallet, broom

Flagstones or brick pavers

Crushed stone, sometimes called paver base

Coarse sand, also called builder's sand

1. Mark off the area you wish to pave. For straight-edged shapes, use stakes and string to mark the space; for irregular or curved shapes, mark the border with flour, flexible garden hose, or rope.
2. Measure the space you've marked, then dust off your math skills and determine its area by multiplying its length by its width. Get enough pavers or flat flagstones to cover the area.

Continued ➔

3. Shovel out the soil to a depth of 4 inches. Use the excavated soil to fill raised beds or for other garden projects. To improve drainage, dig the foundation so that it has a very slight slope of about ¼ inch per 2 feet of space, slanted downward to the edges.
4. Fill the excavated area with 2 inches of crushed stone. Tamp it down firmly with a flat tamping tool or with the end of a 4 x 4 landscaping timber.
5. Top the crushed stone with a 1-inch layer of coarse sand. Tamp it down firmly.
6. Starting with the straightest edge, lay your stones or pavers in place, leaving ¼ inch between them. Leave larger crevices near edges where you'd like to grow herbs or other crevice plants. Use the carpenter's level to make sure adjoining stones or pavers are even.
7. Take a moment to look at the layout of your pavers. If you're happy with how things look, use the mallet to tap each paver into its spot. If your pavers appear uneven or crooked, remove them and re-level the crushed stone and sand base.
8. Toss sand onto the paved area and sweep it into the spaces between the pavers. Sprinkle the area lightly with a hose to help settle the sand into the joints, and add more sand if needed to fill in the crevices.

Whooo's There?

Birds and squirrels will visit a tray feeder by day, but after dark, your tray feeder may host a different clientele, including some who come to dine on the other diners!

Flying squirrels are seed-eaters like their chipmunk and squirrel cousins, but they're active at night. Just because you don't see them doesn't mean they aren't around. Feeders that seem to empty overnight are a clue that these small squirrels are gliding into your feeding station while you sleep.

Mice are quick to find seeds and other morsels on the ground below bird feeders, and they'll quickly adopt a routine of visiting your feeding station for a nightly buffet. Keep the area around your feeders tidy to avoid attracting mice (and their larger rodent relatives).

Opossums eat a wide range of foods, and these curious-looking marsupials may stop by your feeders after dark for a late-night snack. Splay-footed star-shaped tracks around your feeders may be the first sign you see of opossums in your yard.

Owls don't eat seeds, but these efficient predators may fly in on muffled wings to hunt mice that are feasting on fallen bits of food. Since people rarely get to see these carnivorous cavity-nesters, owls can be a good reason to tolerate mice around your feeders.

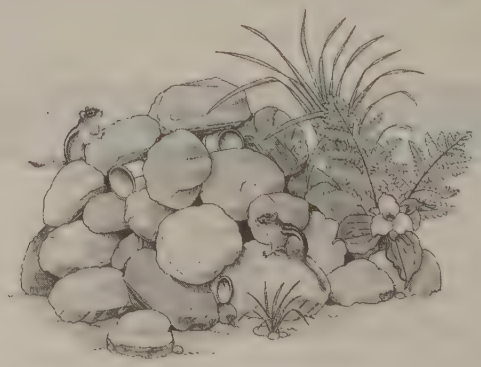
Raccoons may become nightly regulars, especially if you have a water source nearby for their well-known "washing" rituals. Intelligent and persistent, raccoons can become unwelcome garden raiders, so locate feeders as far as possible from your cultivated crops.

Building a Small Mammal Shelter

Sally Roth

The antics of rabbits, chipmunks, and other small mammals are a delight to watch. By supplying an abundance of natural foods and a safe place where they can hide from predators, you can easily encourage these interesting creatures to take up year-round residence in your garden.

Create an inviting home for small mammals like chipmunks and ground squirrels with a loose pile of stones. Add sections of PVC pipe in the pile as you build, making sure that the ends of the pipe are left open. Those holes and tunnels are mighty inviting to small mammals.



Life at the bottom of the food chain isn't easy. Hungry hawks, owls, housecats, and other predators are always on the prowl for small mammals. Give these endearing creatures a fighting chance by constructing safe havens here and there in your garden. A loose pile of rocks will give them plenty of crevices for fast getaways.

Make a Gourd Birdhouse

Barbara Pleasant

Bulb-shaped hard-shell gourds are fun and easy to grow, and they make wonderful houses for birds. Birds don't mind if their house has a natural finish, or you can scrub the gourd with a copper dish scrubber, allow it to dry, and then paint it to create a birdhouse that's pretty and functional. Do be careful to gauge the size of the entry hole to the type of bird you hope to attract, because birds prefer a hole that's so small that predators can't get in to rob the cradle. Some of the most common birds that like gourd houses—and living near people—include wrens, chickadees, titmice, and sparrows. Tailor the house to suit wrens or chickadees by making the entry hole only 1 to 1⅛ inch wide. Titmice and sparrows prefer a 1½-inch-wide entry hole.

You Will Need

Tools: Disposable dust mask, drill with ⅛-inch bit, keyhole saw, long-handled fork or spoon

1 dry gourd, 8 to 10 inches in diameter

2 feet of sturdy, flexible wire

1. Shake the gourd to loosen the seeds inside it. Put on a dust mask (many people are allergic to gourd dust). Holding the gourd on a steady surface, use the drill to start the entry hole: Drill 3 small holes, ¼ inch apart, just above the widest part of the gourd. Enlarge the hole to its finished size with the keyhole saw.
2. Turn the gourd upside-down, and make three small holes in the bottom. Should rain blow into the house, it will drain out through these holes.
3. Shake the loose seeds and membranes out through the entry hole. Then use the fork or spoon to scrape out any remaining loose material. If desired, sand the gourd and then paint it with light-colored exterior enamel paint (dark colors will cause the house to overheat on hot days).
4. Drill 2 small holes on either side of the stem, 1½ inches from the top. Run flexible wire through the holes and twist it over the top of the gourd to form a hanger.
5. Choose a spot to hang the house where your new tenants will be in plain view, but far enough from open windows so you won't be bothered by the chirping of hungry chicks.

Create a Hummingbird Haven

Barbara Pleasant

Hummingbirds don't eat seeds, suet, or fruit, but a combination of resting places, red flowers, and nectar feeders makes an inviting haven for jewel-like hummingbirds. A single sugar-water feeder will attract these zippy flyers to your yard, but they're more likely to stick around your landscape if they also find plenty of tubular flowers to supply them with natural nectar. Fortunately, many of the same flowers that attract hummingbirds also attract butterflies, and the two creatures coexist quite peaceably.

Meanwhile, use a feeder stocked with sugar water to lure hummingbirds close enough so you can see them easily by looking out of your windows. Wait until mid-spring or later, because hummingbirds migrate south in the winter. Setting up an appealing hummingbird site is remarkably simple, and once the tiny birds make a habit of visiting, they will return daily until nature calls them to fly to the tropics in fall.

1. Stretch a thin wire between two posts—such as on a porch or beneath an arbor—and hang one or more nectar feeders from it. Decorate the wire with a few red ribbons or red silk flowers to get the hummers' attention and to keep unsuspecting humans from accidentally running into it. Hummingbirds will sometimes perch on the wire between visits to feeders and flowers.
2. Include flowers that bloom red, and others with tubular blossoms, in your garden, or in pots or hanging baskets. Red petunias, impatiens, or geraniums will attract hungry hummers, as will any color of salvia or lantana. Grow beautiful blue morning glories up the support posts next to the feeders. Hummingbirds find the color red irresistible, but you will often see them sipping nectar from lavender hostas or pink geraniums. Hummingbirds don't read plant lists, and once they find a flower they like, they will return to it again and again.

FEEDER FEATURES AND FILLING

Hummingbird feeders are easily found in supermarkets, chain drugstores, hardware stores, and specialty bird centers. They come in a wide range of prices and styles. Choose a feeder that suits your needs, as well as the birds'. It should be easy to clean and refill, and have a translucent nectar reservoir that lets you see when it needs cleaning or refilling. Also look for guards over the feeding ports, which keep wasps and bees from becoming a nuisance. If the feeder you like best is not made of bright red plastic—the color that catches a hummingbird's eye—just fasten a red artificial flower to it the first few times you put it out. Hummingbirds will quickly figure out that it's the feeder, not the flower, that merits their attention.

Perches aren't necessary on a hummingbird feeder, because these tiny dynamos hover while they drink by lapping with their long tongues. But hummers sometimes will use perches between sips, as will woodpeckers and songbirds that discover the sweet treat. If the competition for nectar at your hummingbird feeder becomes too intense, consider removing the perches or switching to a perchless model.

Continued ➔

There's no need to spend money on commercial nectar mixes. To make nectar for your feeder, combine 1 part sugar with 4 parts water—for example, ¼ cup of sugar to 1 cup of water—and bring the mixture to a boil. Do not add red food coloring, and don't use honey in place of sugar. Food coloring is unnecessary, and honey poses a hazard to hummingbirds' health. Let the "nectar" cool, then fill your feeder. Store any extra nectar in the refrigerator for up to a week. To keep mold from growing in the feeder, clean out any remaining nectar every 2 or 3 days, wash the reservoir and feeding ports, and refill it with fresh sugar water.

Garden Design and Landscape

DESIGNING GARDENS

Designing a Companion Garden

Sally Jean Cunningham

It's easy to have fun with a companion garden. After all, you're not just planting vegetables. You're also planting fragrant herbs and colorful flowers, and you're attracting birds, butterflies, and other wild friends to double the fun! As you've learned, the herbs and flowers do serve a serious purpose. But once you've done the work of grouping your crops and choosing plant friends for them, designing your garden layout and watching your garden grow can be a real pleasure.

Simple garden projects can add new zip and excitement to your garden. Try projects that are both fun and practical, like a toad shelter or a homemade trellis for growing gourds or flowering vines. Fix up a colorful and creative scarecrow. Even if it doesn't scare any animal pests, it will make you smile!

Dream Up a Garden Theme

There are so many ways to play with companion gardens. I like to create gardens with exciting color schemes, just as if I were designing a perennial bed or border. You can also give a garden a regional theme or use lots of trellises and supports to make a vegetable jungle. Once you start, you're bound to come across some great new ideas. Here are a few suggestions to get you started.

A chili-sauce garden. My grandma made a terrific sweet/hot chili sauce, and even in a tough gardening year, I always grow the ingredients for the chili, including onions, sweet peppers, chili peppers, and tomatoes. You may have your own family heirloom chili recipe begging for garden-fresh ingredients. If not, do a little experimenting, and create your own!

A cool cabbage combo. I like to end the gardening season in style with some bright, bold color in my garden. For a great mix of red, blue, and purple, plant red cabbages in a 3-2-3 pattern, and substitute dainty blue cupflowers (*Nierembergia* spp.), love-in-a-mist (*Nigella damascena*), and rocket larkspur (*Consolida ambigua*)

Continued ➔

for some of the heads of cabbage. At each end of the bed, plant purple garden mums. I don't know whether all the flowers in this combination are helpful companions, but they certainly help lift my spirits on a sunny fall day!

Stir-fry flair. Chinese vegetables are mostly cool-weather crops, so you can create a bed just for fun and early winter salads, stir-fry, or Chinese specialties. Some of the Chinese vegetables to try include Chinese cabbage, celery cabbage, daikon radish, Chinese broccoli, mizuna, and Chinese spinach.

Some like it hot! There are some wonderful hot colors in both flowers and vegetables that you can combine to make a sizzling "hot garden." Try planting a bed of tomatoes and peppers with bright red salvias, Mexican sunflowers, and tall, red-orange marigolds. Scatter tall red cosmos throughout. Mix in some red cabbage, red basil, and scarlet runner beans. Then give it all a border of bright red petunias.

A festive fence of beans. Grow a multicolored bean fence using a combination of dry beans, purple beans, and yellow wax beans. Just plant each seed in sequence, spacing them 7 inches apart along a fence or trellis. If you use varieties that have a similar number of days to maturity, you can harvest your own colorful three-bean salad all at once!

Three Fun and Fanciful Designs

I think vegetables have as much right to be in the front yard as any other kind of garden, so one of my designs is for a salad garden to highlight the foundation and front walkway of a suburban home.

Vegetable gardens can be very pretty, especially when we mix in flowers to create companion gardens. And successful vegetable gardeners want to show off what they've grown (especially if the garden says "Look what you can grow organically!"). Plus, the front yard is often the place with the right sun or soil for a vegetable garden.

The garden includes all the vegetables and herbs you need for a terrific salad, and even the flowers in it are edible.

Just one note when you're planting edibles in your front yard. Keep them away from the edges of driveways or streets where they can be contaminated by road salts or automobile exhaust.

The second design is a circular garden that I've called the wheel garden because the plan looks like an old-fashioned wagon wheel with paths for spokes. Between the spokes, there are wonderful combinations of vegetables, herbs, and flowers.

My third special garden design is a great choice for gardeners with limited space. I call it the Small TALL Garden because it uses lots of trellises, arbors, and towers to maximize production in small beds.

All of these gardens meet the basic definition of companion gardens: The crops are grouped in families, the garden includes lots of flowers and herbs, and everything's intensively planted in raised beds. I did make some concessions, perhaps adding a few more flowers than I would have in a garden where production was the primary goal. And in some cases, rotating crops is a bit harder. But making these adjustments is worth it to me for the extra excitement these gardens provide.

CHOOSING VARIETIES

In most cases, I haven't specified what varieties of crops or flowers to grow, except for a few specific varieties that have special qualities. For example, 'Siam Queen' basil has lovely purple flowers that add excitement, and 'Purple Wave' petunias have a spreading habit that makes them a wonderful groundcover. For the vegetable crops, it's important for you to choose varieties that grow well in your local area and that have flavors you like! Don't be afraid to substitute for crops that you wouldn't eat. For example, I frequently use Swiss chard in my gardens because I really like it. But I know lots of people who'll politely pass it by at the table. If you're in the "no Swiss chard" crowd, just substitute another leafy crop that you enjoy eating.

Here's the layout for my front-yard salad garden. The garden has four beds, each 3 feet wide and 20 feet long (the equivalent of a conventional 15- by 20-foot garden). Here, they're arranged to flank a pathway leading to the front door. You can arrange the beds in any way that suits your front yard. For example, if you have a curving walkway that leads from your driveway to your front door, you can lay out the beds on either side or both sides of the walk.

To make this garden extra-special, I used *only* edible flowers, so anybody can go out to harvest supper. The edible flowers include pansies, violets, petunias, and daylilies. (In this garden, we *do* eat the daisies!)

PLANTING THE GARDEN

In the plant list below, numbers in parentheses indicate how many transplants, bulbs, or sets to plant. Plant other crops from seed; one packet should be plenty.

PLANTS FOR A FRONT-YARD SALAD GARDEN

Vegetables

Beans (pole varieties)
Carrots
Cherry tomato (1)
Cucumber (1)
Kale
Leaf lettuce
Mesclun (mixed salad greens)
New Zealand spinach
Onions (24 to 36)
Peas (tall varieties)
Radishes
Romaine lettuce
Spinach
Swiss chard
Tomatoes (4)
Zucchini (1)

Herbs and Edible Flowers

Basil (3)	Johnny-jump-ups (12)
'Siam Queen' basil (3)	Garden mums (2)
Bee balm (10)	Nasturtiums
Borage (2)	Pansies (20)
Calendulas (10)	Parsley (2)
Chives (2)	'Purple Wave'petunias (2)
Daylilies (2)	Rose, 'The Fairy' or other shrub type (2)
Dill	Salad burnet (1)
Gladioli (6 to 12 bulbs)	Sweet William (8)
Hollyhocks (5)	Violets (9)

Any round garden is a perfect place to practice crop rotation. In this case, I've planted a circular garden 20 feet in diameter with a 4-foot-wide "hub" or center circle. The garden is divided into six wedge-shaped beds with 18-inch-wide paths in between. To reduce or enlarge the garden, just make the beds shorter or longer.

Managing the garden. The best management strategy for this garden will be to work the soil well before you first shape the beds and not to till after that. Keep the soil covered with mulch or cover crops, and create permanent wood-chip paths between the beds. You can till the garden by tilling in a spiral from the center out, but only if you use a temporary path covering like grass clippings or straw, Even in a fanciful garden like this, I suggest planting a cover crop like buckwheat every few years to rebuild the soil.

The garden hub. Your round garden doesn't have to have a plain circle of grass or mulch at its hub. Use the space for a fun garden project. I can picture a comfortable lawn chair next to a birdbath or a tall ornamental grass like maiden grass (*Miscanthus sinensis*). You could even plant a small apple tree for shade.

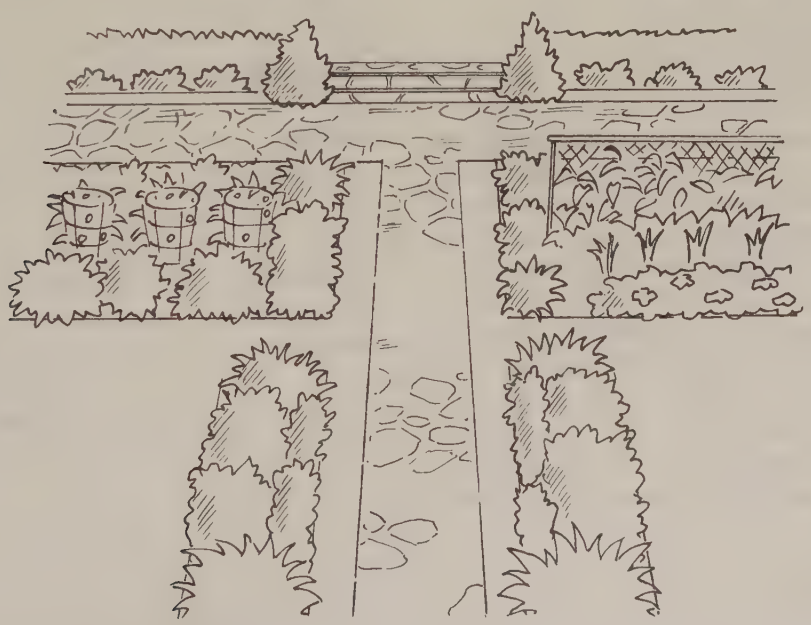
Other possible "centerpieces" include a water garden in a tub or a large pot of Jerusalem artichokes surrounded by mint. (Let the plants tussle for space while you breathe in the mint scent and harvest some crunchy tubers.) Just be sure to leave enough space around the center planting for weeding, watering, and harvesting.

Planting the garden. In the plant list below, numbers in parentheses indicate how many transplants or sets to plant. Plant other crops from seed; one packet should be plenty.

PLANTS FOR A WHEEL GARDEN

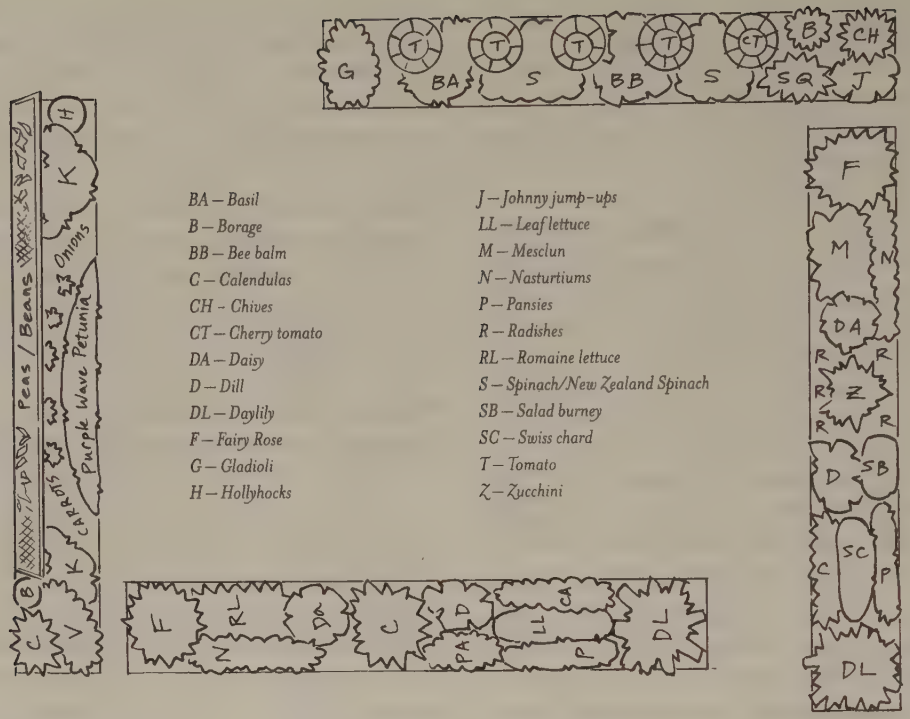
Vegetables

Beans (bush variety and pole variety)	Potatoes (16)
	Radishes
Broccoli (9)	Spinach
Cucumber (2)	Summer Squash (1)
Kale	Swiss chard
Lettuce (leaf variety)	Tomatoes (4)
Peas (tall variety)	Cherry tomato (1)
Peppers (12)	Zucchini (1)



A front-yard salad garden. If you have a sunny lawn in your front yard, liven it up with raised beds full of salad fixings, including edible flowers.

Continued



Herbs

Basil (12) Dill 'Siam Queen' basil (8)

Flowers

Buckwheat	Gazanias (2)
Calendulas (10)	Ornamental kale (7)
Cleome (3)	Nasturtiums (5)
Cosmos (3)	Sweet alyssum (12)
Yellow cosmos (5)	Zinnias (9)

If you read gardening magazines, you've probably noticed that it's often city gardeners who have the most creative small gardens in their tiny yards or on their balconies and rooftops. I lived in New York City many years ago, and I remember how small city lots can be. So I designed a small-space companion garden to grow maximum crops in a minimal space. The design includes lots of trellises and arbors (that's why I call it the Small TALL Garden). It's great for anyone who wants lots of production in a small space, whether in the city, suburbs, or country.

There are six beds, each 3½ by 7 feet. Arching arbors connect pairs of beds across a center path. The center path is 4 feet wide (but you can adjust the width to suit whatever arbors you build or buy).

Plant supports. You can use many kinds of cages, trellises, or fences to grow pole beans, tomatoes, and vine crops like cucumbers and winter squash. In this design, the vine crops grow over a "tent" made of heavy wire mesh that is nailed over a hinged frame.

You'll also notice a strawberry tower in one bed. I think the price of the tower is worth it for the luxury of harvesting fresh strawberries from a small garden!

Planting the garden. In the plant list below, numbers in parentheses indicate how many transplants, crowns, or sets to plant. Plant other crops from seed; one packet should be plenty.

PLANTS FOR A SMALL TALL GARDEN

Vegetables

Asparagus (5)	Onions (24 to 36)
Beans (pole varieties)	Peas (tall varieties)
Carrots	Radishes
Cucumbers (3)	Spinach
Daikon radishes	Summer squash (1)
Gourds (4)	Strawberries (16 to 20)
Kale	Swiss chard
Lettuces (mixed varieties)	Tomatoes (3)
Melons (3)	Zucchini (1)
New Zealand spinach	

Herbs

Basil (7)	Fennel (3)
Chives (2)	Parsley (2)
Coriander (3)	Italian parsley (6)
Dill (3)	

Flowers

Calliopsis (6)
Love-lies-bleeding (3)
Marigolds (5 to 9)
Mexican sunflowers (5)
Sunflowers
Swan River daisies (2)

Ornamental Climbers

Climbing rose
Silver lace vine (*Polygonum aubertii*)

TWO SPECIAL CLIMBERS

Two special flowering ornamentals, a climbing rose and silver lace vine, are beautiful and easy to grow.

Climbing roses. When I look for a climbing rose, I want one that's disease tolerant, pest-free, and hardy to the colder side of Zone 5 (preferably Zone 4). Not too many roses fill the bill. I've selected 'Henry Kelsey' as one of those few, reported by many rosarians as the best climbing rose for northern areas. It produces vigorous shoots laden with blooms that have deep red petals and contrasting gold stamens. 'Henry Kelsey' blooms from summer through the first frosts.

Other candidates for this situation are 'William Baffin' (deep pink, hardy to Zone 3), 'Leverkusen' (medium yellow, hardy to Zone 4 or 5), and 'John Cabot' (medium red, hardy to Zone 3).

Silver lace vine. If you plant silver lace vine, you may end up with a vine 25 to 30 feet long by the end of the summer. In areas with cold winters, silver lace vine may die back in winter and "only" grow 15 feet the following year. This vigorous vine likes full sun or partial shade and prefers dry, well-drained soil.

If silver lace vine sounds too aggressive for your taste, there are other easy climbers to try. Dutchman's pipe (*Aristolochia macrophylla*) can grow to 15 to 20 feet but is easy to control by cutting back each winter. It sports huge heart-shaped leaves and delicate, 3-inch, tubular, yellow flowers. Ever-blooming or climbing honeysuckle (*Lonicera sempervirens*) is fragrant and long-flowering and likes rich, well-drained soil and full sun or partial shade.

Creating Your Own Designs

I hope my fun designs and ideas trigger your creativity. Just remember, you don't have to make huge changes in your gardens all at once. You can start with something as simple as planting one bed in a new location or in a new shape. Try an oval or triangular bed. Or create a small companion-garden bed as a highlight in your front lawn. Why not, when you're mixing so many colorful flowers and herbs among the vegetables!

Gardening and Landscaping Design

gardens and shade trees, you probably have some landscape problems—especially in those shady spots.

If you'd like to improve your yard's appearance, you may want to try designing your own landscape plan. You may feel intimidated by the thought of creating your own design. It seems like a huge undertaking that requires special skills and training. But the truth is, you can easily improve your yard using some basic ideas and techniques that are also used by professional designers. Choose a project you can feel confident trying. You can give your whole yard a face-lift, redesign the backyard only, or just redo the area around your patio.

Be creative. Whatever the scale of your project, you'll find that landscaping especially with perennial flowers, is a great chance to be creative and have fun. Perennials can express your personality—your likes, dislikes, and style. For example, if you're a collector at heart, you'll aim to grow as many different plants as you can, not worrying about the fine points of design. Or, you may find that perennials bring out the artist in you. You'll thrive on plotting borders and rearranging plants to present an exquisitely planned garden picture every season of the year.

As with any creative process, there's more than one way to tackle designing a landscape project. If you're a natural organizer, you'll enjoy mapping your project and developing plant lists. If you're a spur-of-the-moment sort, you may never get the details on paper. But whatever your style, take some time to read or browse through the process of developing a landscape plan presented here. You're sure to find tips and examples that will help you shape your ideas. Then take a walk and look at gardens. You'll find ideas for garden styles as well as plants that are well-adapted to your local climate. Take snapshots of appealing plantings—they'll be reminders when you're drawing up designs.

Trust yourself. As you develop ideas, remember that there are no wrong answers when it comes to landscaping with perennials, just different ones. Experiment! Grow plants that appeal to you. Don't worry too much about following rules. Talk to other gardeners and look at their gardens. Try to learn from their successes and failures. But above all, have fun.

Using Design Terms

A perennial garden isn't just one kind of garden. That's one of the things that makes them so fun and exciting to plant. But the terms used to describe the different categories of perennial gardens can be confusing. Understanding the terms is useful in developing landscape ideas, though, so it's worth your while to sort them out.

Mass plantings. Mass plantings are group plantings of a single kind of plant. Easy-care, low-maintenance plants are the best choice for mass plantings. For a low-maintenance garden on

a sunny, dry site, masses of 'Autumn Joy' sedum, black-eyed Susans (*Rudbeckia* spp.), daylilies, or ornamental grasses would be spectacular.

Mixed plantings. Mixed plantings are a variety of plants growing together in one garden. They combine herbaceous perennials with trees, shrubs, vines, annuals, and other plants. They're a perfect choice for a site that needs year-round interest—they don't leave a bare expanse of ground in winter.

Perennial beds. A garden along a patio or foundation or at the edge of the lawn is usually called a bed. Island beds are plantings—perennials alone, or a mixed planting—surrounded by a sea of lawn. Beds are designed to be seen from more than one side. Because beds are for viewing close up, plant them with perennials that have long flowering periods and attractive foliage.

Perennial borders. Borders are longer than beds and generally are planted along a fence or at the boundary of a yard. Borders can also edge one or both sides of a walk or driveway. They're usually designed to be seen from one side only. A garage, fence, or hedge behind a border provides an excellent backdrop. Masses of asters, 'Autumn Joy' sedum, chrysanthemums, daylilies, peonies, Siberian iris (*Iris sibirica*), and ornamental grasses all make fine plants for a sunny border.

The Possibilities of Perennials

Perennials make any yard a special place to be. Whether they're arranged in practical, low-maintenance plantings or jumbled together in cheerful confusion, perennials add color, fragrance, texture, and movement to the landscape. As shown in the sample landscape on the following page, perennials are multipurpose plants that can reduce maintenance, create mystery, welcome visitors, attract wildlife, and much more. Keep the possibilities of perennials in mind as you launch your own plan for redesigning some or all of your property.

Sizing Up the Views

Imagine living in the middle of a garden. Flowers and foliage surround you. Patterns of sunlight and shadow play upon the ground, and pleasant fragrances waft by on the breezes. A flower-lined path leads off in one direction, beckoning you to follow it into a shady clump of trees. A glance in another direction reveals a bench surrounded by herbs and sun-loving perennials. Why not put your house in the middle of that garden?

All too often, we think of gardens as out in the yard somewhere—completely separate from the house. But the most satisfying home landscapes surround the house with the garden.

Think for a minute. How often do you look out your kitchen window? If it's 10 times a day, that's 3,600 times each year. What could be nicer than to see beautiful flowers outside every window? That's what putting your house in a garden means.

This isn't as difficult to accomplish as it might seem. Fortunately, you don't have to plant flowers on every square inch of your yard. You will need to spend some time thinking about the placement of your perennial plantings in relation to your house.

It's all too easy to make spur-of-the-moment choices and end up with flowerbeds scattered randomly around your yard. But for gardens that give maximum pleasure, begin by discovering what parts of your yard are visible when you're inside, looking outside. Once you know that, you can plant perennials to fill the spaces framed by your windows and create views that will put a smile on your face every time you see them.

START INDOORS

Gather up a pencil and a sketchbook or notebook, and spend a few minutes looking out each window of your home. Linger longer in front of windows that are most important to you—the kitchen or living room windows, perhaps.

Draw an outline of each room and indicate where the windows are. Make notes or pictures of what you see—flowerbeds, trees, the patio, the garbage cans, the neighbor's pool, a park across the street, mountains in the distance.

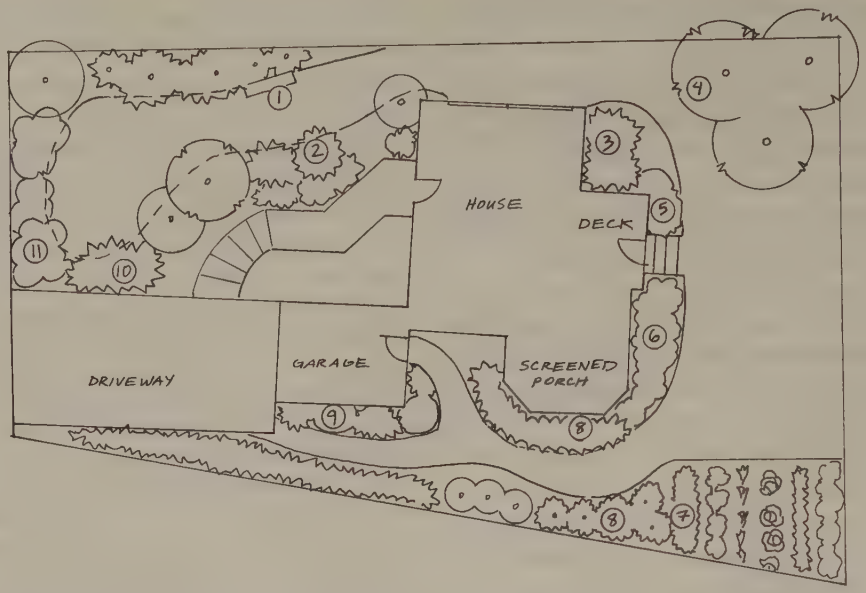
Next, write down your ideas for improving the view, or any other ideas that pop into your head. Would a cluster of shrubs make the patio seem cozier and more appealing? How about adding flowerbeds along a walkway? What about planting herbs and flowers under the window in the breakfast nook?

If trees and shrubs have obliterated the view from a window, try to look past them and think what you might see. If the window overlooks the neighbor's house or a busy street, you may want to leave things as they are. But if a shrub or tree branch blocks an otherwise beautiful view of your garden, consider doing some selective pruning to improve the view.

Plan for "Face" Value

To give your house an appealing public face, take a look at it from the street, too. An effective design will add a neat, welcoming look to a house. It creates attractive views for your neighbors, and will delight you every time you return home. Here's an added bonus: Studies show that when you sell your home, you'll realize a return on investment of 100 to 200 percent on money spent on landscaping.

Continued



1. *Create an outdoor retreat. A garden bench surrounded by perennials is a wonderful spot to relax, relieve stress, and enjoy the beauty of nature.*
2. *Add eye appeal. One of the best reasons to plant perennials is simply that they're beautiful. They'll add appeal to your yard whether they're planted in the lawn, around a patio, along a walkway, at the edge of your yard, or in front of a fence.*
3. *Direct traffic. Sweeps of perennials planted along walkways help guide visitors. And large clumps of perennials, ornamental grasses, and shrub roses will discourage people from taking shortcuts you'd rather they not try.*
4. *Eliminate maintenance monsters. Replace scraggly grass and eliminate tedious trimming under trees by planting hostas and other shade-loving perennials.*
5. *Furbish your foundation. Low-growing perennials and evergreen groundcovers make great easy-care foundation plantings. Best of all, they don't need all the trimming typical foundation shrubs do.*
6. *Bring the outdoors in. Surround a deck or patio with a flower garden you can see from the inside as well. Or plant a colorful and fragrant bed you can enjoy every day from your kitchen window.*
7. *Hide the uglies. Ornamental grasses and tall perennials, like 8-foot tartarian asters (Aster tataricus), can screen the view of a vegetable garden that's past prime or hide the neighbor's garbage cans. Combine them with shrubs for year-round screening.*
8. *Frame a fabulous view. Plant perennial gardens you can see from inside your house, especially from dining and living room windows.*
9. *Dress up ho-hum features. Surround an otherwise plain garage or edge dull-looking steps with cheerful perennials to dress up your landscape in one easy step.*
10. *Transform trouble spots. There are perennials that will grow in nearly any kind of soil and in conditions from full sun to full shade. Sedums and many herbs will thrive in hot, dry sites, like the area along this paved driveway. Moisture-loving perennials like hostas, astilbes, and ferns will transform a wet site from an ugly quagmire into a garden.*
11. *Greet them with flowers. Why grow lawn in the front yard when flowers will dress up your house and welcome visitors, too? For a bed that's attractive year-round, mix in plants with long bloom seasons and foliage that's evergreen or remains attractive after plants finish blooming.*

CHECK THE BIG PICTURE

After you've checked all your window views, go outside and look from your garden back to your house. Walk around the edges of your yard and follow paths you normally travel. Then, get off the beaten track so you have a fresh view of your house and the surrounding yard.

Again, jot down your ideas as you walk. Look at the "fit" between the house and the landscape. Is it a rambling, comfortable-looking house that seems surrounded by stiff, uncomfortable-looking plantings? Does the house look "plopped down" on the lot—a huge structure surrounded by scattered gardens that seem too small?

Don't worry about solving these problems now. We'll get to that in the coming sections. For now, just record your impressions so you can refer to them later.

Evaluating Your Yard

What details of your yard can you picture in your mind's eye? Does it have walkways, raised beds, steps, or terraced slopes? How big are they and what do they look like? What are the problem spots that need improvement? These details are the foundation of your landscape. As you create your new landscape, you'll use perennials to improve these features and also to add new features.

If you're someone who thinks on paper, it's best to make a written site assessment of your yard's features. (Visual thinkers may do this more informally, with just a few jotted notes.) Taking snapshots is also a great way to record the features of your yard.

Take a tour of your front, back, and side yards. As you go, sketch your yard and make notes about what you have to work with. Your goal is to collect as much information as you can, and

also to begin cooking up landscape ideas that might appeal to you. Use the list below to help you decide what to record.

Your house. Describe the exterior of your house from all angles. Include distinctive details, the style and mood of the architecture, and the materials the house is made of.

Solid features. These include walks, walls, fences, terraces, lampposts, decks, and outbuildings (such as sheds). Note the materials they're made of and the style or mood they suggest. Also make notes about whether their style seems compatible with your house.

Plants and gardens. Note the locations of individual large trees and shrubs, shrub borders, wooded areas, or foundation plantings. Also include the outlines of flower and vegetable gardens.

Utilities. Your design will need to accommodate underground cables, septic fields, and other utilities, so don't forget to record their approximate locations.

Water. Mark streams and ponds if you have them, as well as water spigots, rain barrels, or other water sources.

Traffic patterns. Formal walkways aren't the only traffic routes in your yard. Record unofficial paths as well—your route to the garage or compost pile, and the cut-through to the neighbor's yard. Make a note if paths need to accommodate a garden cart or wheelbarrow, and record areas where cars are occasionally parked or driven.

Shade and sun. Observe your yard at several times of day to see which parts are shady or sunny, and which receive sun or shade for only part of the day.

Problem spots. Challenging sites like slopes, wet spots, rock outcrops, and areas with compacted soil will figure prominently in your design, so mark them down.

BUT DO YOU LIKE IT?

It's all too easy to get caught up in visual details—like walkways and lampposts—at this stage. After you've dealt with what you see, try to write down your feelings about your yard. What areas appeal to you? What are the eyesores you'd like to hide or redo?

You'll probably end up with a jumble of sketches and notes. Later on you'll sort them and figure out what you really have time and room to do. For now, dream happily, get to know your yard, and reach for as many ideas as you can imagine.

What's Your Style?

Understanding your personal style—whether you are quiet and contemplative or exuberant and colorful, for example—is an enormously powerful design tool. It will help you figure out what you want and need in your garden, as well as what kinds of garden features *aren't* suited to your personality.

Think about the way you like to do everyday tasks such as setting the table or keeping house. The way you accomplish them can say a great deal about the kind of garden you'd enjoy most. For example, when you set a table, do you prefer the cheerful confusion of mismatched tableware, or the quiet simplicity of matched pieces? Your answer says something about whether you would feel more comfortable in a riotous cottage garden where flowers tumble over one another, or in an elegant formal garden with orderly beds of flowers.

Is your house comfortably "lived-in," or is it neat and orderly, with everything in its place? The answer to this question will not only help you discover the right garden style for you, it may help you avoid maintenance nightmares. For example, if you prefer the everything-in-its-place approach, a garden with bold, clean lines and wide, easy-to-maintain paths is probably a good choice. You'll also probably be less able to tolerate the sight of faded flowers, flopping stems, and scruffy foliage than someone who loves the lived-in look. To keep maintenance manageable, choose plants that need minimal deadheading, stand tall without staking, and remain attractive through the season.

FORMAL OR INFORMAL?

If you like well-organized flowerbeds in regular patterns, you prefer formal gardens. If fluid, free-form beds are more your style, informal gardens will appeal to you. Nearly all gardens are either formal or informal in style, although some use elements of both styles. Here are some characteristics that distinguish the two.

Formal style. Gardens with a formal style look peaceful and balanced. They feature rectangular, oval, or round beds; sheared, geometrically shaped hedges and evergreens; and stone, brick, concrete, or gravel walkways. Materials, shapes, or plantings—such as boxwood hedges—are repeated throughout the garden. You'll often see statues, sundials, and simple water features in formal gardens.

Informal style. Informal gardens are more dynamic and exciting to look at than formal ones. Natural, organic-looking shapes predominate. Instead of brick walkways, you'll see mulched paths and rustic features like split-rail fences. And instead of matching beds of perennials, an informal garden might feature two free-flowing beds with unmatched mixtures of flowering shrubs and perennials.

SPECIAL STYLES

The existing conditions in your yard will also influence the style of your gardens. Your yard may have a grove of mature trees that cries out to be underplanted with an informal garden of shade-loving hostas, wildflowers, and azaleas. Perhaps your yard already has some formal rectangular beds and clipped hedges. You may decide to add your personal touch by planting some of

Continued ➔

your favorite perennials in the existing gardens. Incorporating existing "hardscape," like brick pathways, is usually a good idea, too.

The style of your house can and should affect the landscape you plan. You'll be most satisfied if they harmonize with each other. For example, if you have a single-story ranch house, a large, free-spirited cottage garden filled with tall perennials could overwhelm the front yard. Or, if you have a home with period architecture—Colonial or Victorian, for example—you may want a garden that features plants from that era.

Regional style also can determine the kind of gardens you plant. Mediterranean-style gardens are classic California choices; an informal planting of prairie plants might be a good Midwestern choice.

Here are some of the most popular special styles for American gardens.

Colonial style. This style can be quite formal, with boxwood hedges or knot gardens of clipped lavender cotton (*Santolina chamaecyparissus*). But Colonial gardens can also be informal mixed beds filled with herbs, like lavender and thyme, and old-fashioned flowers, like cranes bills (*Geranium* spp.), peonies, pinks (*Dianthus* spp.), and violets.

Country style. Rustic and relaxed looking, country-style gardens are generally informal, although they may have formal features like square beds or weathered brick terraces. The plants are a joyful jumble: herbs, salad greens, and old-fashioned perennials like daisies, hollyhocks, irises, and peonies.

Cottage style. Plants take center stage in a cottage garden. These informal, even wild-looking gardens feature old-fashioned perennials, like primroses (*Primula* spp.) and pinks (*Dianthus* spp.); fragrant roses and other flowering shrubs; herbs; and reseeding annuals like sweet alyssum. Narrow paths allow plants to be enjoyed up close.

Mediterranean style. Sunbaked terraces, fragrant herbs, and formal, rectangular pools are classic features of Mediterranean gardens. Shady sitting areas under trees, awnings, or umbrellas provide relief from the sun. Paved areas—and the containers that decorate them—often feature terra-cotta and various ceramics.

Modern style. Formal or informal in style, modern gardens feature bold, simple shapes and strong contrasts. Mass plantings create striking groups with different colors and textures, using plants such as ornamental grasses, yuccas, showy stonecrop (*Sedum spectabile*), and large-leaved hostas.

Natural landscapes. These informal gardens are inspired by nature's gardens. They feature plants that are native to the region—or at least look as if they are. Natural materials (native stone walls, for example) and areas designed to attract butterflies and other wildlife are also characteristic of natural landscapes.

Putting Your Ideas Together

You've probably discovered by now that you've gathered an exciting array of ideas for your landscape. You have views to improve, features to highlight and others to screen from sight, garden styles to try, and an impressive list of "must grow" perennials.

There are any number of ways to sort through your ideas. If you have a computer, you can type them all in and organize them with the stroke of a key—or move them around with a mouse, for that matter. If you're a list maker, sheets of lined paper and a pencil may suffice. An easy, low-tech way to organize your ideas is to write them out on 3 x 5 cards.

SORT YOUR IDEAS

Gather all your notes, sketches, and snapshots, and spread them out on a table. (An out-of-the-way spot where you can leave them for several days is ideal.) You'll also need a pack of 3 x 5 index cards and/or some lined paper, as well as a couple of sharp pencils. Depending on how fancy you want to get, colored pens, pencils, or markers may come in handy, too.

To turn the 3 x 5 cards into a handy system for sorting out all the ideas you've gathered, write each of your major ideas onto a card. Start with the ideas you came up with when checking views out windows and around your yard. If that's an overwhelming number of ideas, just make cards for the most important ones. For example, you may have imagined a mixed bed of perennials and flowering shrubs around the terrace in front of the living room window.

Next, make cards for each of the major features of your yard. You'll want ones on both good and bad features—major trees and shrubs, existing plantings, hardscape features like concrete walkways and walls, utility areas, and problem sites like slopes or wet spots.

Finally, look over your notes about the garden styles that appeal to you. Make a card for each type of individual garden and planting you'd like to have. For example, you may want an herb garden, a country garden, and a planting that attracts butterflies.

Now you have a neat stack of cards. Look through them and think about what you've missed. Ask yourself—and other family members—what you want and need your landscape to do. Nongardening family members will have definite opinions, too: You may need an area for playing ball, working on a car, or placing a swing set. Or you may want a spot for growing divisions of your great-aunt's peonies or a frog pond—make cards for them, too. (You also may want to use colored markers to color-code the different kinds of cards or to rank the importance of the ideas.)

PLAY THE GARDEN GAME

It's time to transform your ideas into garden projects. Have you already started to see links between your ideas? For example, would raised beds or terraces on the sunny slope turn it from a

problem into the perfect spot for the herb garden you've always wanted? If so, put those cards together in a pile. Could you position the herb garden so it provides a pleasing view from the kitchen window? If so, add that card to the pile, and so forth.

As you sort your cards, look for ways to combine different ideas into a single garden or planting. For example, many of us would love to have a perennial border, an herb garden, a rose garden, room for a peony collection, and a bird garden. But most of us don't have enough space or time to devote to so many different gardens. Try combining all those ideas: A perennial border easily could include herbs, low-maintenance shrub roses, the peony collection, and flowers that attract hummingbirds. Rosehips and seed from perennials and flowering shrubs would provide food for seed-eating birds; a birdbath or small rock-edged pool would provide water.

You'll have cards that don't fit easily into any of your piles. Some you'll have to discard. With others, you may just have to look for the best fit. If you want a private outdoor retreat but don't quite know where to put it, you may want to write "Outdoor retreat?" on several cards and put it into several of your piles to serve as a reminder that you want to include that feature.

When you finish, each pile represents a project to tackle. Keep the cards! When you get ready to design your bed or border, your pile of idea cards will help you decide what kinds of plants to include. Cards on views and problem spots in the same pile will remind you of important issues, such as the need to make your border visible from the living room and the path to the neighbor's yard that must be maintained.

Mapping and Planning

Fern Marshall Bradley

Make a Working Map

A working map of your yard will help you get from the idea stage of landscaping to the *doing* stage. You'll use your working map as the base sketch for drawing landscape plans, calculating how much space you have, determining how many plants you'll need to buy, and much more. Your map doesn't have to be an artistic accomplishment. Think of it as a picture of what you're starting with.

The first thing you need to do is gather materials: one standard and two colored pencils, a ruler, a clipboard, scrap paper, some large sheets of graph paper and tracing paper, and a compass.

If you have a survey map of your property, dig it out, too. You can draw your working map on a photocopy of the survey map, or just refer to it to draw the outline of your property. If you don't have a survey map, you can locate your property corners as you make your map.

You'll also need something to measure with, such as a 100-foot measuring tape, along with a helper to hold one end. Or you can make a homemade measuring device fashioned from stakes, string, and tape. First, tie one end of a long (200 to 250 feet) piece of string to a stake. Then measure and mark 10- or 20-foot intervals along the string. Wrap the marked string around the stake and tie the free end to a second stake.

To use the measurer, stake it at the point you're measuring from, then stretch it to the feature you want to locate. Count up the marks along the string, multiply by your interval (10 or 20 feet), and that's the distance.

Next, make a list of features in your yard to include on your map. Include the property corners (unless you're using a survey), existing plantings, and all other features.

Step-by-Step Mapping

There's a simple mathematical technique that will help you draw an accurate map. It's called triangulation. But before you start drawing, you must measure the distances to all the features on your list from a set of reference points. Here's what to do:

1. Sketch your property on a piece of scrap paper. Use this to record measurements.
2. Pick two reference points to measure from, such as the two corners on one side of your house. Measure the distance between the two reference points and write it on your sketch.
3. Circle each reference point with a different color pencil—say red and blue. You'll record all the measurements made starting from the red reference point in red and from the blue reference point in blue (this will help you keep things straight later on when you're drawing your working map).
4. Measure the distance from one of your reference points to a feature on your property that you want to map, such as a tree or the corner of a perennial border. (If you want to map the boundaries of your yard, the first measurements you should take are the distances from your reference points to the corners of your property.)
5. Measure the distance from the other reference point to the same feature. (Be sure you're using the right color pencil to record the distances!) Record these measurements either on your features list or on your map, whichever is more helpful to you as you work.
6. Repeat steps 4 and 5 for all other important features in your yard.
7. Go inside and start drawing your map on graph paper. Choose your scale, and pencil in your reference points.
8. Using triangulation, mark the location of each feature you measured onto your map.

If your yard has lots of features to record, you may want to alternate measuring and mapping, plotting just three or

Continued ➔

four features at a time. Or if you're good at keeping notes and numbers organized, you may be able to do all your measuring in one outdoor session. Either way, work carefully because accuracy is the most important feature of a working map.

If you don't have a helper when you're measuring, try this variation on the technique. Pound in a stake at one reference point and attach your measuring string or tape to it. Then measure the distance between that reference point and several features, moving the free end of the tape or string from feature to feature. Then switch and measure from the other reference point to the same features.

You may need to pick new reference points when you switch from measuring your front yard to your backyard, or to map features that are un-reachable from your first set of reference points.

You'll bring your personal style to the map you make. The detail-oriented among us probably will enjoy drawing an accurate scale map; others may find it tedious and end up with a looser rendition.

Whatever you think of the process, consider it a one-time investment in your landscape design. Once you've drawn it, you can lay sheets of tracing paper over the map to sketch endless design variations. Or, you can make a set of photocopies of the original map and sketch directly on them. Either way, you can draw to your heart's content and never have to redraw your working map.

Read on for more features that you'll want on your working map before you begin designing.

Get Personal with Problem Sites

You know where they are—those nasty sites that bog down your mower, turn into raging rivers during rainstorms, or sprout lush crops of weeds no matter what you do. An important part of planning your landscape is finding solutions for those problem sites. To design a plan that does away with problem sites forever, you need to get to know them "up close and personal." As you find the problem sites in your yard, mark them on a copy of your working map for reference.

RAMBLE IN THE RAIN

There's no better way to figure out what to do about surface water drainage than to get an umbrella, put on a pair of galoshes, and go outside during a rainstorm. You'll see firsthand where water cuts runoff paths across your property, as well as where it puddles up. Don't plan to simply direct this water off your property and into the storm sewer as quickly as possible. Instead, look for ways to slow or redirect its flow and help it soak into the soil.

Solving runoff problems. You may be able to redirect water that flows across your yard or puddles next to your foundation by bringing in soil to build up a berm. Treat the berm like a raised bed and plant it with shrubs, ornamental grasses, and perennials.

Another option is to plant the site with perennials like daylilies that will tolerate the runoff. Or, you can double-dig the soil and/or add terraces to slow the flow of water. Double-dug soil will hold a considerable amount of water, especially if you cover it with a heavy layer of mulch.

Solving puddling problems. Sites where water tends to puddle are perfect for moisture-loving perennials like hostas, ferns, and Japanese iris (*Iris ensata*). Another option is to dig a water garden—but before you do, check whether the site collects water from neighboring yards as well as your own. If any of your neighbors use garden chemicals, those chemicals may end up in your yard, possibly killing the fish or plants in your water garden.

SCRUTINIZE YOUR SHADE AND SUN

Take time to look for sunny and shady pockets in your yard. Knowing where they are will help you pick the right plants for your landscape. To really figure out sun and shade patterns, you'll need to observe your yard several times during the course of a day. Some sites never get any direct sun—on the north side of your house next to an evergreen, for example. Others are sunny or shady only in the morning or afternoon. Note patterns on a copy of your working map, using slashing lines in one direction to indicate morning sun and another direction for afternoon sun.

CHECK THE TRAFFIC

Check your yard for compacted soil and scraggly grass—the signs of unofficial pathways. Accommodate these paths rather than fight them. For example, if an unofficial path to the neighbor's house runs through a site you covet for a perennial border, plan to install stepping-stones through the border.

MULL OVER YOUR MOWING

During your next few mowing sessions, notice what your mowing problems are. Are there awkward spaces around shrubs or trees? Slopes that leave you panting? Rough areas of scraggly grass that are hard on the mower—and you? Target these areas for planting with groundcover or mass plantings of perennials.

SEARCH FOR SAD SOIL

Stunted plants—or no plants at all—are one clue that your soil is less than wonderful. Problem soil areas may need cultivation or generous enrichment with organic matter. Or, you may just need to figure out what types of plants would be happy in those conditions. You'll learn more later about matching plants to soils. For now, just make note of problem areas.

Draw Your Dream Landscape

Now that you've brainstormed ideas, mapped your property, and made special note of problem sites, you're ready to create a landscape plan. Drawing a landscape plan is something like putting together a jigsaw puzzle. The objective is to blend all your ideas and the existing features of your landscape into a

picture that will please you. It's a fun and creative process, as well as a challenge. But don't worry, you don't have to be an artist to create a workable design. And remember, you don't have to make a plan for your whole property. You may want to draw a plan for just your front yard, for example.

SKETCH YOUR IDEAS

To start, gather the 3 x 5 cards or other notes that summarize your ideas. You'll also need the working map of your landscape, pencils, a ruler, sheets of tracing paper, and any ideas you've collected from books or magazines.

Put a piece of tracing paper over your working map. You'll sketch ideas on the tracing paper, which is usually called an overlay. (You can use photocopies of your map instead if you prefer.) You may want to pencil in some reference points (like the outline of your house) on each overlay before you start sketching. This will help you realign the overlay if it shifts position while you're sketching.

Review the pile of cards that has your most important ideas in it. For example, you may want a perennial garden in a sunny spot that you can see from both the kitchen and the living room. You may have a specific site in mind—the only spot that's in full sun and visible from both rooms, for example—or there may be more than one site that would work.

Next, start sketching ovals or rectangles on those sites to represent the garden. At this point, stick to general concepts. You'll work out detailed bed shapes and plant choices later. Landscape plans of this sort are often called "bubble diagrams," and one is shown on page 693.

When you're done with the first pile of cards, move on to the next one. As you work, look for connections between spaces—you may find activities that seem to fit together. For example, if you position an herb and flower garden next to a sitting area, you'll get extra enjoyment from your garden when you sit outdoors.

Whenever you have too many ideas on an overlay, cover the overlay with a new sheet of tracing paper. Trace the parts of the design you like, and continue drawing. (Since you may want to refer back to previous overlays, don't throw any of them away until you have a finished design.)

You probably will run out of landscape space before you run out of ideas. If you do, try to incorporate leftover ideas into areas you've already assigned. In the end, you may have to discard some ideas. Just be sure they are the ones that are least important to you. If they aren't, go back and rework your design to fit them in.

MAKE A PRACTICALITY CHECK

Before you draw up a final plan, take a minute to step back and look critically at your plan. Two important practical considerations are installation costs and required maintenance. For example, say your rough design features a brick walkway flanked by two 100-foot perennial borders. Do you have the money to buy all those plants and bricks, and the time to maintain such large plantings? Perhaps two smaller borders of mixed groundcovers and a crushed stone walk would be more practical and economical. You could design a smaller perennial garden at another site.

If you're planning on stone walls or brick walkways, make a few phone calls to find out approximate costs of materials. This safeguards you from getting stuck in an overly ambitious project.

FORMALIZE YOUR DRAWING

A final, detailed drawing of your plan will help you calculate your material needs for walls and walkways, tally how many plants you'll need, and figure out the best way to install your new landscape.

Start with your working map, your bubble diagram, and a new sheet of tracing paper. You may want to collect some tools that will help you draw shapes: A compass and a triangle may be helpful, especially for formal designs. For drawing informal sweeping curves, experiment with a set of French curves and/or a flexible curve (a flexible wire coated with plastic that has one flat side you can trace against). Both of these drawing tools are available at craft and office-supply stores.

You'll use these tools to create customized shapes in place of the simple ovals or rectangles on your bubble diagram. It's easiest to start with a defining feature in your plan—perhaps a sweeping bed around a clump of trees or a long, low wall along a slope. Draw that feature in first; it will help you figure out how the rest of the elements will fit. For example, you may want to echo the shape of the bed you drew around the trees on the other side of your yard.

Another excellent option is to use a grid to structure your design. Using a grid helps ensure that your plan puts your house at the center of your garden.

THE FINISHING TOUCHES

There's a saying that "good bones make good gardens." Although gardens don't seem the least bit bony when they're in the full flush of summer bloom, well-designed gardens do have a structure that holds them together to create a unified picture. These bones (structure) are the shapes, colors, textures, and materials repeated throughout a garden. The bones of a garden are especially important in winter: When perennials are dormant, the bones are still there to make your landscape pleasant to look at. The bones of a garden also often help guide visitors from one part to another.

Create a structure. Using a certain material throughout your garden creates its bones. Stone, brick, or flagstone in walls, terraces, and walkways become garden bones. Trees and shrubs, especially evergreens, also serve as garden bones, as do evergreen groundcovers. Hedges and fences also can play a role in the bones of your garden.

Continued →

Plan to use several materials or types of plants to create the bones of your garden. For example, you may want to use rug junipers to edge crushed stone walkways throughout your garden, and then set off your perennial plantings with a backdrop of mixed evergreens and an edging of blue fescue (*Festuca cinerea*) in front to echo the color of the evergreens. In summer, the structure of your garden could take on a whole different dimension if you use yellow- or blue-flowered perennials throughout.

Connect the spaces. As you look at your plan, imagine how visitors will walk from one area to the next. For example, if you plan a flowerbed around your patio, how will your visitors know not to tramp across your perennials in winter? You may want a low fence or hedge to separate the patio from the garden, as well as a pair of evergreens or stone pilings on either side of the designated path.

Repeat shapes. Repeated shapes create harmony. Use rectangles, ovals, or sweeping curves that echo one another—such as the edges of mixed plantings along either side of a yard.

Simple is effective. For small yards, a simple, formal garden is often most effective. Or plan on a design with strong structure—like a path that winds into the backyard between beds of mixed flowers and shrubs.

Balance garden and open space. Take an extra look at the shapes defined by areas of lawn, patios, or mass plantings of groundcovers. Designers call this the negative, or open, space in a design. Open spaces should have clean, pleasing shapes. A central oval- or hourglass-shaped lawn is much more visually pleasing than a lawn that has complicated zigzag edges. Strive to balance the negative space and positive (filled-in) space, which you'll plant with perennials, shrubs, trees, or mixed groundcovers.

Look for outdoor room. Try to enclose some areas, at least partially, with shrubs and perennials or hedges. Add easy-care shrub roses, ornamental grasses, and perennials around a patio to screen it from neighboring yards.

Include surprises. Paths that wind out of sight, stepping-stones that lead visitors through a garden, or unexpected clumps of color in an otherwise green landscape create surprise and fun in your garden.

VISUALIZE YOUR DESIGN

It's tough to imagine what your rough drawing will look like as a finished landscape. For a test, try to imagine yourself actually doing things in your planned yard. Are there paths to follow, sitting areas to enjoy? Does your yard have spaces for all the activities you enjoy?

To get an idea of how large you'd like your plantings to be, try piling up plastic bags filled with leaves or arranging lawn chairs on a proposed site to get an idea of the total volume of plants. If you're trying to either screen a particular view or make sure you don't cover one up, have a helper hold up a pole to estimate how tall you'll need your plantings.

Snapshots of your house are a good visualizing tool. Sketch in rough shapes of the proposed plantings on the photos (or photocopies of the photos).

Prioritize Your Projects

Once you've polished your plan on paper, it's time to inject a little dose of reality. Much as you'd like to plant your entire dream landscape right now, undoubtedly you don't have enough time, money, and muscle to do so. You need to take a hard look at your plan and pick the project or projects that you want to implement first.

One way to choose is to start with the site you see most clearly from the house. Or, you may decide to start with the project that will be the most enjoyable, such as planting the shady wildflower garden you've always wanted. Solving your worst maintenance nightmare often comes out as top priority.

When you're choosing your "do-first" projects, try to include one simple project on your list: The reward of seeing one finished, lovely spot in your unfinished yard is worth it.

MAKE A PRACTICAL PLAN OF ACTION

In most cases, you'll install your priority projects over time. Simple projects may take only a weekend or two. But depending on your budget, how ambitious your projects are, and the time you have to spend, others may take as long as several years to complete. That's one of the reasons having a simple project high on your list is so important. You can plant a small bed around a lamppost or on either side of a short set of steps in a single weekend, giving you pride in accomplishment and readying you to tackle more complicated projects over a longer span of time. Here are some suggestions to help you with scheduling.

Plan around hardscape. If your plan calls for adding a patio, house addition, walls, or walkways, don't plant around those sites until the building project is complete. Otherwise, you'll spend time repairing plantings after construction.

Plant woodies first. Give trees and shrubs a head start by planting them first, especially if shade is at a premium in your yard. As they're growing, you can add perennials and groundcovers as time and budget allow. If you're planning an island of trees and shrubs, mulch them well after planting to control weeds. Then gradually plant perennials among the mulch.

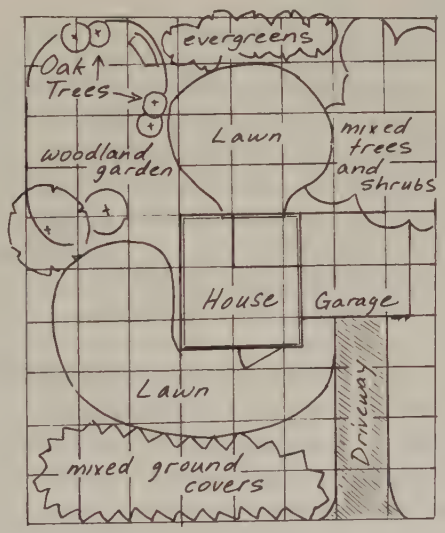
Mulch and grow. You can avoid digging on some sites by trying no-dig soil improvement. Scalp all weeds on the site, then cover it with a newspaper layer 12 to 15 sheets thick. Then spread 4 to 5 inches of straw, and top it off with 2 inches of decorative mulch. If you have it, add 1 inch of compost under the mulch.

Consider a Grid

A grid is nothing more than a series of squares drawn on a piece of tracing paper and placed over the working map of your landscape. The secret is that the size of the squares and their placement relate directly to your house, and the garden is designed around the grid squares. This helps to create a landscape plan in which the gardens and other features are proportional to your house.

Pick a prominent feature to base the grid on. In this example, each grid square is the same size as the existing patio. Major plantings generally take up one or more individual grid squares.

Don't select a grid square that's too small. It leads to a fussy, overcomplicated design. After you draw in your grid, fill in landscape features, working out from your house. This will ensure that the landscape unfolds from the house and the house is at the center of beautiful gardens.



You can make planting holes right in the mulch, fill them with purchased soil, and plant them with annuals to cover the site in the summer. Keep the site mulched for a year, then plant with perennials.

COST-CUTTING TIPS

There's no doubt about it, installing a landscape can be expensive. Sometimes doing it yourself is the best option; other times it's not. Here are some tips to help you keep your pocketbook under control.

Learn a skill. Check books out of your local library or attend a workshop to learn a landscape skill like bricklaying or building stone walls.

Rent, don't buy. You can rent nearly any kind of equipment or tool to make landscape installation easier. Instead of hiring someone with a tractor or buying one yourself, rent one to move soil or accomplish other tasks that your landscaping plan requires.

Use nursery services. If your plan calls for large trees and shrubs, having the nursery plant them may pay off in the long run. Many nurseries will guarantee specimens they plant, but extend a more limited warranty for specimens you plant yourself.

Opt for local materials. Consider a variety of materials for each project, then select the one that's least expensive in your area. Limestone paving slabs may be much cheaper than bluestone in some areas, for example. Also keep an eye out for used materials you can acquire—used brick, for example.

Before You Plant

So you've settled on your top-priority project and you're ready to go! But as one last step, check out the microclimate and soil on your project site. This information helps in selecting the right plants for the site.

CLIMATE ON A SMALL SCALE

The amount of shade or sun a site receives is just one factor in the microclimate of a site. If you haven't already determined how much sun and/or shade your site receives, read "Scrutinize Your Shade and Sun" on page 690. Also evaluate the wind, exposure, and slope conditions.

Wind. Prevailing winds can wreak havoc with perennial plantings—drying plants out, ruining blossoms, and blowing them over. If your site is windy, consider making a windbreak part of the project. A fence is a quick solution, but barrier plantings will last longer and provide better protection.

Exposure. South-facing sites along a building or wall are generally warmer and more exposed in winter than north-facing ones. And the extra heat given off by the wall or fence behind a south-facing site warms these sites in spring. For this reason, they're a good place to plant spring bulbs. But broad-leaved evergreens can suffer from leaf scorch on a south-facing site both in summer and on unusually warm winter days.

Plants on a north-facing site are protected from both winter and summer sun. And west-facing sites that receive afternoon sun tend to be hotter than east-facing ones.

Slope. Perennial groundcovers are fairly easy to establish on slopes. But if you plan to plant a mix of perennials, you'll need to build terraces and level planting beds.

Planning terraces requires a little mathematical figuring. The first step is to measure the rise and run of the slope. From that, you can figure out how many terraces you'll need.

Continued ➔

LOOKING AT WHAT'S DOWN UNDER

Complete your site examination by taking a look at the soil. Dig a few test holes with a garden fork or spade. Poorly drained soil, compacted soil layers, and too-sandy or too-clayey soil are some of the common problems you may face. Certainly, you can work to improve your soil before you plant. But in the long run, your plants will do best if you match their needs to the soil. For example, if you have very light, sandy soil, perennials like ligularias (*Ligularia* spp.) that need rich, moist soils just won't grow well.

If you strike rocks repeatedly while you're digging, consider building a raised bed over the area or planting shallow-rooted groundcovers around the rocks. Another option is to dig up some of the larger rocks and stack them in a low wall.

Roots are another matter. If you hit roots at every turn, you are dealing with a shallow-rooted tree.

Secrets of Successful Combinations

Putting perennials together in great combinations is easy and fun. What's more, creating combinations of perennials is the first, most important step in designing an entire perennial garden from scratch.

In the preceding section, you've worked through the process of deciding where you want to plant perennials in your yard and what styles of gardens you want. Now you're ready to try designing beautiful combinations of perennials.

In this section, you'll find a series of perennial combinations with explanations of how color and design principles were used to choose the plants. You'll learn how to work with attractive foliage, plant forms, and other features in perennial combinations. Once you understand how to put plants together in attractive combinations, you'll find it a natural progression to design an entire perennial garden.

DESIGNING WITH COLOR

Many gardeners find designing with color intimidating. They're afraid they'll make a mistake and combine flowers that don't look attractive together. Or they're simply overwhelmed by all the plants to choose from—each more beautiful than the last!

The key to comfort with combining colors is to get out there and experiment. Try out some of the combinations you see in this book, or design some of your own. Granted, you may end up with a dreadful combination or two. But that's what shovels are for—you can always move one of the offending plants somewhere else and try a new combination the next year.

Using the Color Wheel

In elementary school art classes, you probably learned about the primary colors—red, yellow, and blue—and how to mix them to make other colors. Those early experiences playing with paints are similar in some ways to combining colors in gardens.

The color wheel can provide the basis for choosing good perennial combinations if you know how to use it. It can also help you look at color more critically and figure out what's working in a particular combination and what isn't.

For example, *complementary* combinations—blue and orange, red and green, yellow and violet—have lots of contrast and are bright and exciting to look at. Colors that harmonize share the same pigments—yellow, yellow-orange, orange, and orange-red, for example. You can make stunning combinations by starting with complementary colors—violet and yellow, for example—and then adding harmonizers, such as blue-violet and red-violet, to the picture.

Flowers usually don't come in the pure colors you see in the wheel. Instead, you'll be dealing with colors like peach, lemon yellow, apricot, burgundy, deep purple, or lilac. Sometimes surrounding colors can influence our perception of color. To determine a flower's true color, try holding a solid white card behind the bloom to neutralize the influence of nearby foliage.

You'll find that light also influences color. Combinations that are so-so in the early morning can literally glitter in late afternoon sun. Ornamental grasses are particularly spectacular when backlit.

GETTING STARTED

Besides color, when you design combinations you'll also want to consider things like plant height and form, leaf shapes, and bloom time. It can get complicated! Try not to get lost in the "rules" of garden design. If you do, you may forget what's really important—filling your yard with plants that appeal to you and grow well together. That's not to say you should throw all design principles out the window. If you look closely at great-looking combinations and gardens, you'll see that flower shapes, heights, forms, and textures all play a role in the design. And repeating certain elements—like color or texture—throughout a design help it become a unified, visually appealing picture.

As you look at the plant combinations that follow, keep in mind that color preferences are highly subjective. You may not like all the color combinations you see here. Figuring out what you do like is most important. In fact, you're sure to like the combinations you design if you use your favorite colors.

Don't get caught up in trying to apply all these principles at the same time—there's simply too much to remember. Just use them as well as you can. And remember, a shovel is your plant eraser. You can always add new plants or move some if your combinations don't turn out quite right at first. You'll find out that's half the fun!

Contrasts Create Excitement

This lush perennial garden uses contrasts between plants to form a dynamic picture. At the same time, it also uses repetition—plants that look alike in some way—to pull the garden together. The rounded mound of 'Autumn Joy' sedum, which echoes the shapes of its individual blooms, provides a

solid, clean-looking anchor for the planting. It balances the exuberant and unruly explosion of New York ironweed above it. The white-striped foliage of the variegated Japanese silver grass, echoed in miniature by the creeping lilyturf in the front of the border, provides color and texture contrast to the sedum. And the ribbonlike shape of these two plants repeats in contrasting colors both in the rough-stemmed goldenrod blossoms and the ironweed leaves.

DESIGN KEY

1 'Autumn Joy' sedum (*Sedum* 'Autumn Joy')
2 Rough-stemmed goldenrod (*Solidago rugosa* 'Fireworks')
3 New York ironweed (*Vernonia noveboracensis*)
4 Variegated Japanese silver grass (*Miscanthus sinensis* 'Variegatus')
5 Purple coneflower (*Echinacea purpurea*)
6 'Moonbeam' coreopsis (*Coreopsis verticillata* 'Moonbeam')
7 Smoke tree (*Cotinus coggygria*)
8 Creeping lilyturf (*Liriope spicata*)

Mass Plantings Make a Bold Statement

In mass plantings, blocks of color and texture take precedence over the shapes of individual flowers. This planting features flowing drifts of color, which is more effective than hard-edged rectangles of plants. Note that the heights of the plants vary so each mass of color shows to best effect.

A mass planting is especially effective from a distance, where the bold blocks of color would be most dramatic. Planting at a distance has another advantage: You can enjoy all the color without having to worry about picking off spent blooms.

DESIGN KEY

1 Shining coneflower (*Rudbeckia nitida* 'Herbstsonne', also called 'Autumn Sun')
2 Spotted Joe-Pye weed (*Eupatorium maculatum* 'Atropurpureum')
3 Feather reed grass (*Calamagrostis acutiflora* 'Stricta')
4 Brazilian vervain (*Verbena bonariensis*)
5 Feathertop grass (*Pennisetum villosum*)

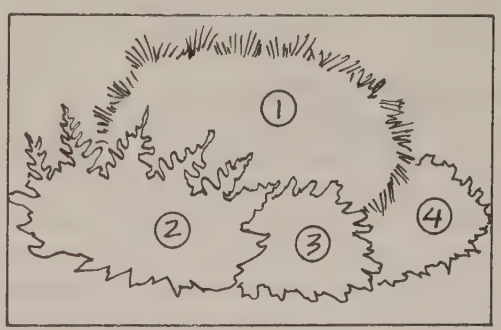
Use Foliage for 4-Season Color

Great gardens are more than just flowers! As perennials come in and out of bloom, foliage is fundamental for keeping a garden looking its best. That's why it often makes sense to mix evergreen shrubs in perennial beds and borders.

This mixed planting will have foliage interest year-round. The dwarf eastern white pine and 'Blue Star' juniper will provide winter color. In summer, the Chinese astilbe foliage will remain green and attractive all season, while the fine foliage of 'Moonbeam' coreopsis provides a colorful skirt for the garden.

DESIGN KEY

1 Dwarf eastern white pine (*Pinus strobus* 'Nana')
2 Chinese astilbe (*Astilbe chinensis* var. *pumila*)
3 'Blue Star' juniper (*Juniperus squamata* 'Blue Star')
4 'Moonbeam' coreopsis (*Coreopsis verticillata* 'Moonbeam')



Combine Tall and Short Plants for Heightened Interest

Vines clambering on trellises add a casual country look to a bed or border. They're a perfect solution if you need nearly instant height in a newly planted bed, or if you have space for only a narrow border. In a deep border, you can create contrasts in height by planting clumps of 5- and 6-foot-tall perennials at the back, and scale down to 1-foot mounds at the front. But in tight spaces, tuck a vine like this Jackman clematis at the back of the border to add height. (Since vines grow up, not out, they don't need the space that larger perennials require.)

Continued →

Clematis like to grow with their heads in the sun and their feet in the shade, so this type of site is ideal. If you need extraquick results, try annual vines like morning glories trained in a similar manner.

DESIGN KEY

1 Jackman clematis (*Clematis jackmanii*)

2 Hybrid delphinium (*Delphinium elatum*)

3 Persian onion (*Allium aflatunense*)

Choose Plants That Suit Your Site

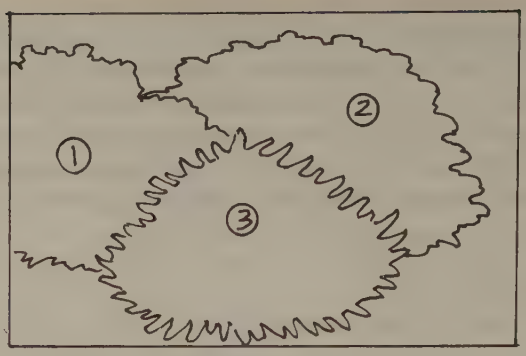
Matching plants that will grow well together is the secret to planting an attractive garden that stays that way. Once you've selected several plants that you think would look nice together, check out the cultural conditions they require. You'll have the best results, if you stick to plants that all need the same type of site and soil. In this garden, even though the 'Autumn Joy' sedum is much more drought-tolerant than the 'Montgomery' Colorado spruce, both will grow well in rich, well-drained soil. Note that these garden companions will also make an arresting winter picture. Both sedum and 'Goldsturm' black-eyed Susan have attractive seedheads that persist through winter, and the spruce will add a spot of silver-blue.

DESIGN KEY

1 'Goldsturm' black-eyed Susan (*Rudbeckia fulgida* 'Goldsturm')

2 'Autumn Joy' sedum (*Sedum* 'Autumn Joy')

3 'Montgomery' Colorado spruce (*Picea pungens* 'Montgomery')



Use Dramatic Plants to Accent Your Landscape

Specimen plants like August lily are the exclamation points of garden design. Technically, a specimen plant is one that is grown alone in the landscape so its shape and form can be appreciated from all sides. Use one to mark the entrance to a garden path or set off one part of your yard from another. But be judicious: Too many exclamation points can create confusion—and lots of obstacles to mow around.

The best specimen plants are attractive for much or all of the growing season. Shrubs or small trees are an obvious choice, but large hostas or heucheras (*Heuchera* spp.) also make great specimen plants in a shady garden. For a sunny site, you might use variegated yuccas or large ornamental grasses.

DESIGN KEY

1 August lily (*Hosta plantaginea*)

2 English ivy (*Hedera helix*)

Match the Shape of a Garden to the Site

Shapes, texture, and movement play important roles in the design of this lush foliage garden. The fountain sets the shape of the bed and the plantings in it. Water pouring from the jug in the child's arms seems to cascade out into the garden to create ripples of plants. The net effect is a sculpture integrally linked to the setting: It's hard to imagine it without the surrounding plants.

DESIGN KEY

1 'Palace Purple' heuchera (*Heuchera micrantha* 'Palace Purple')

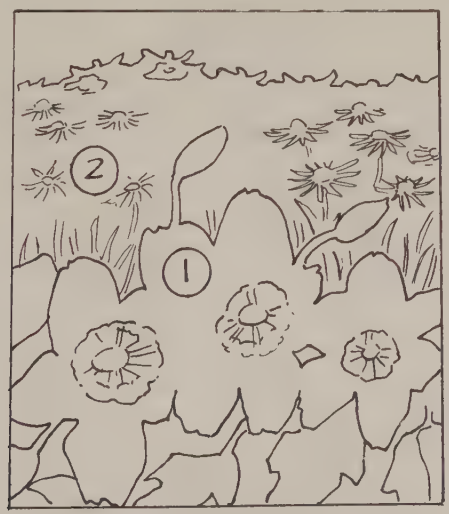
2 'Silver Carpet' lamb's-ears (*Stachys byzantina* 'Silver Carpet')

3 Artemisia (*Artemisia* sp.)

4 'Goldmound' spirea (*Spiraea* 'Goldmound')

Watch for Great Combinations That Happen by Chance

You can blanket your yard with blocks of annuals and be able to predict with some certainty that it will look the same in June, July, August, and September, but what fun is that? Perennials create their own combinations, and those combinations change all the time. One plant may spill over onto another, as these Japanese anemones have toppled onto asters. Or, one year a perennial may bloom earlier or later than normal, creating a combination you hadn't planned. As the years go by, perennials also reseed and spread to make their own combinations—some good, some bad. Your job as the master color coordinator is to guide your plants with a gentle hand toward color combinations you find appealing, however long they last.



DESIGN KEY

1 Japanese anemone (*Anemone x hybrida*)

2 Aster (*Aster* sp.)

Combine Complementary Colors

One way to start a design is with complementary colors like yellow yarrows and lavender-blue cranesbills. Select the complements you want to use and then build around them by picking different flowers in similar colors.

When you try to select perennials of a particular shade, you'll find that flower color isn't always easy to define. For example, if you check descriptions in several mail-order catalogs for *Geranium* 'Johnson's Blue', you'll find it described as brilliant blue, clear blue, lavender-blue, and blue. Because flower colors are difficult to capture on film and in print, photographs of it vary as well—you'll see depictions from brilliant blue to lilac. In the end, the only true test is to grow the plant in your own garden and decide for yourself what color it is.

DESIGN KEY

1 'Johnson's Blue' cranesbill (*Geranium* 'Johnson's Blue')

2 'Moonshine yarrow' (*Achillea* 'Moonshine')

Plant Ribbons of Hot Color for Maximum Impact

When subtle just won't cut it, bright, cheerful hot colors may be the answer. Hot colors are the color of fire-red, orange, and yellow. They pop out in the landscape and make things look closer than they really are. Bright clumps of color at the back of this landscape seem to pop out in front of the green foliage that surrounds them.

DESIGN KEY

1 Bee balm (*Monarda didyma*)

2 Coneflower (*Rudbeckia* sp.)

3 Threadleaf coreopsis (*Coreopsis verticillata*)

Continued ➔

Use Cool Colors for Calming Effects

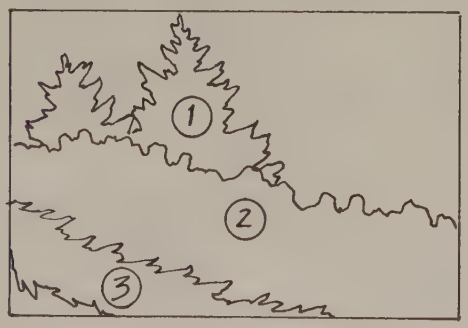
Rows of cool colors are at the forefront of this elegant spring scene. Cool colors are the color of water—blue, green, and violet, as well as silver, gray, blue-green, and gray-green. They create a garden with a serene feeling, and they also appear to make things recede. A small garden planted with blues and purples, for example, will look larger because everything seems farther away. Pale pink is also considered a cool color, while hot pink is a hot color.

DESIGN KEY

1 Blue atlas cedar (*Cedrus atlantica* 'Glauca')

2 Bearded iris (*Iris* bearded hybrid)

3 Juniper (*Juniperus* sp.)



Startling Color Contrasts Can Make Stunning Combinations

Although pink and orange aren't high on many gardeners' lists of plants they'd like to see growing together, they work beautifully together in this garden. The pink plumes of 'Superba' fall astilbes, set off against dark green foliage, set the tone for this scene. Beyond the fence, the lilies act as an exclamation point that foreshadows more excitement in the border beyond. Yellow lilies alone would have worked, but the garden would lack that "Look at me!" excitement.

DESIGN KEY

1 Lilies (*Lilium* spp.)

2 'Superba' fall astilbe (*Astilbe taquetii* 'Superba')

Use a Color Theme to Unify Your Garden

Gardens that celebrate a passion for a certain color like yellow, blue, or white have a long tradition in perennial gardening. Whether you plant just a corner of your yard with your favorite color or use it to fill an entire garden, it's great fun sleuthing out all the color possibilities. For example, there are hundreds of yellow-flowered perennials to choose from.

Yellow tulips, daffodils, irises, and primroses would extend the summer color scheme of this planting into the spring. Plants with variegated leaves, such as golden-striped ornamental grasses or *Yucca filamentosa* 'Bright Edge', or gold-colored foliage, such as golden oregano (*Origanum vulgare* 'Aureum'), are also a great option.

DESIGN KEY

1 'Statuesque' daylily (*Hemerocallis* 'Statuesque')

2 'Coronation Gold' yarrow (*Achillea* 'Coronation Gold')

3 'Moonbeam' coreopsis (*Coreopsis verticillata* 'Moonbeam')

Don't Forget the Power of White Flowers and Foliage

White is actually a strong color that can hold its own against more brightly hued garden residents. In this garden, white plumes of delphiniums and steely silver flowers of giant sea holly are every bit as bright as the yellow daisylike flowers of heartleaf oxeye. White is also useful for mediating disputes between clashing colors in a border. For example, a white bank of baby's-breath between clumps of orange-red lilies and pink cranesbills (*Geranium* spp.) can do wonders. Silver-leaved plants like 'Powis Castle' artemisia also make effective moderators. In an emergency, you can also add clumps of annual dusty miller between color combatants.

DESIGN KEY

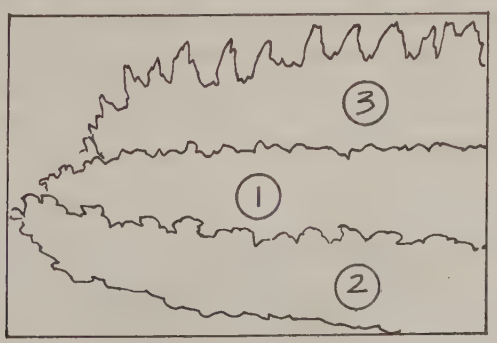
1 Giant sea holly (*Eryngium giganteum*)

2 Delphinium (*Delphinium* hybrid)

3 Heartleaf oxeye (*Telekia speciosa*, also known as *Buphthalmum speciosum*)

Design with Rivers of Color

One look along a country roadside during the height of summer will confirm that nature isn't subtle about painting colors across the landscape. You can take a cue from nature and plant your garden in meadowlike drifts of color. This technique is especially effective in large borders that you'll view from a distance. In a small garden, you can get a similar effect by planting a few clumps of each perennial. Either way, planting color drifts reduces the hodgepodge effect that can result when a garden has too many small dabs of color.



DESIGN KEY

1 'Goldsturm' black-eyed Susan (*Rudbeckia fulgida* 'Goldsturm')

2 'Autumn Joy' sedum (*Sedum* 'Autumn Joy')

3 Foerster's feather reed grass (*Calamagrostis arundinacea* 'Karl Foerster')

Include the Backdrop in Your Design

This border has it all. Clumps of soft color march across the garden providing height and a sense of movement. It also has something that's easily missed: a deep green hemlock backdrop that sets off the soft colors of the perennials. The color scheme of this border would fade away against a light backdrop.

Before you plan a garden, take a minute to figure out what you'll see it against. If you are planning a perennial bed or island that you'll usually see silhouetted against the lawn, consider brighter colors that would stand out against grass green. And while perennials will show effectively against a solid board fence or dark siding, consider your colors carefully if your house is white, yellow, or pastel-colored.

DESIGN KEY

1 Mullein (*Verbascum* sp.)

2 Penstemon (*Penstemon* sp.)

3 'Autumn Joy' sedum (*Sedum* 'Autumn Joy')

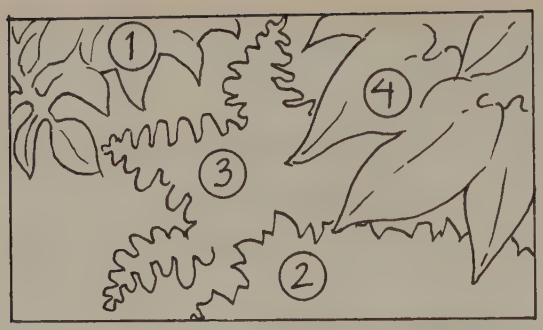
4 Speedwell (*Veronica* sp.)

5 Clary (*Salvia sclarea*)

Plan around Foliage Colors

Since most perennials bloom for only a few weeks in summer, foliage is often the real workhorse that keeps a garden looking great day in and day out. The spring green hosta leaves light up this shady garden as much as the fleeting pink flowers of dame's rocket. The clump of lady fern makes an especially interesting companion: Although it is the same green as the hosta, its lacy leaves stand out against the dark forest floor, creating a stunning textural contrast.

Continued ➔



DESIGN KEY

1 Pagoda dogwood (*Cornus alternifolia*)

2 Dame's rocket (*Hesperis matronalis*)

3 Lady fern (*Athyrium filix-femina*)

4 'Piedmont Gold' hosta (*Hosta* 'Piedmont Gold')

Foliage Makes the Show in Shade

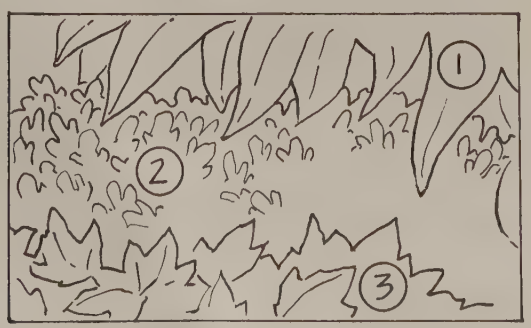
Foliage can light up a shady garden all summer if you'll let it. There are plenty of perennials with variegated leaves that will add color and interest to even the darkest spot. In addition to the ones shown here, hostas, hardy cyclamen (*Cyclamen hederifolium*), and variegated Solomon's seal (*Polygonatum odoratum* 'Variegatum') will bring whites, golds, yellows, and greens to your garden. All add flowers for at least a few weeks. In this small corner of a garden, the mazus provides a carpet of white flowers and the lungwort bears rosy wine blooms to herald spring.

DESIGN KEY

1 'Excalibur' lungwort (*Pulmonaria* 'Excalibur')

2 White-flowered mazus (*Mazus reptans* 'Albus')

3 Persian ivy (*Hedera colchica* 'Dentatovariegata')



Combine Plants with a Goal of Season-Long Color

One of the challenges of working with colors in a perennial garden is that the colors of individual flowers come and go. One way to plan a summer-long display of color is to take a spring combination like this one and look for later-blooming perennials that will repeat it in other seasons.

Try peonies with Siberian iris (*Iris sibirica*) or maiden pinks (*Dianthus deltoides*) with bellflowers (*Campanula* spp.) for early summer bloom. Follow it up with balloon flowers (*Platycodon grandiflorus*) and bee balm (*Monarda didyma*) for summer. Sum up the year with hot pink and blue asters.

DESIGN KEY

1 Tulip (*Tulipa* hybrid)

2 Forget-me-not (*Myosotis* sp.)

3 Lamb's-ears (*Stachys byzantina*)

Perennials Can Provide Great Fall Color

Colors can signify the season as clearly as the weather. Fall brings silvers, bronzes, yellows, and golds to gardens as surely as it puts a nip in the air. Fall's colors are more subtle than those of the early spring and summer garden, but they are no less beautiful. This late fall garden won't be finished with the first frost of the season. And many of the plants here will continue to provide color and interest through the winter. Ornamental grasses will turn a lovely beige, adding color and texture until they're cut to the ground in early spring. Seedheads of sedums, which turn paler bronze, and coneflowers, which turn dark brown, will stand through the winter as well.

DESIGN KEY

1 'Sarabande' Japanese silver grass (*Miscanthus sinensis* 'Sarabande')

2 'Powis Castle' Artemisia (*Artemisia* 'Powis Castle')

3 Aster (*Aster* sp.)

4 Cleome (*Cleome hassleriana*)

5 Butterfly bush (*Buddleia* sp.)

6 Purple smoke tree (*Cotinus coggygria* 'Royal Purple')

7 Purple coneflower (*Echinacea purpurea*)

8 Lamb's-ears (*Stachys byzantina*)

9 Salvia (*Salvia* sp.)

10 'Autumn Joy' sedum (*Sedum* 'Autumn Joy')

Planning a Perennial Garden

Fern Marshall Bradley

Start with Your Plant List

Spend ten minutes browsing at a well-stocked garden center or paging through mail-order catalogs, and you'll find there's no shortage of perennials to choose from. It's a cinch to find 50 or 60 perennials you'd love to grow. The challenge lies in winnowing down that list to select the plants that will look best and grow best in your garden.

If you're like most gardeners, you love the annual onslaught of catalogs with their tempting offerings. But it's easy to get caught in the trap of buying everything that looks and sounds appealing. Making a plant list is the best way to ensure that you buy wisely. It takes time but allows you to evaluate each plant, as well as make comparisons between plants.

You're not a list maker? Are you prone to impulse purchases? Or are you simply overwhelmed when you visit a garden center or try to wade through catalogs? Don't despair. Try one of these suggestions for developing a list of plants.

Start with your site. Choose plants with your site conditions in mind. If you have a hot, sunny site, consider only plants that will thrive under those conditions and eliminate all the others. If you're tempted to buy whatever looks interesting or new, take a written summary of your site conditions with you to the garden center. Hold it in your hand as you compare your description to the cultural information on the plant labels. If they don't match, don't buy!

Review your style. Picking a garden style or color scheme first can help you pick plants. A cottage garden theme, for example, suggests old-fashioned reseeding perennials and biennials like peach-leaved bellflower (*Campanula persicifolia*) and foxgloves (*Digitalis* spp.).

Start your design with classic plants that epitomize your style. If you have a particular color scheme in mind—yellow and blue, for example—that narrows your choices as well. And if you like cutting and arranging flowers, you may want to choose perennials with bloom colors that will match the colors of the furniture or wallpaper in your dining or living room.

Build on combinations. Select a perennial combination and check whether it will grow well on your site. If it will, use that combination as the basis for your design. This will focus your search.

Keep in mind that gardens don't have to contain lots of different kinds of perennials to be beautiful and satisfying. You can also create a perfectly lovely garden simply by making mass plantings of the two or three plants in one combination.

Include some sentiment. Planning beds and borders around plants that provide special memories adds a wonderful dimension to any garden. Perhaps there are specific plants that remind you of happy childhood experiences, dear friends or relatives, or a neighborhood where you used to live.

For example, if plants have been passed down through generations—like peonies that grew in a grandmother's garden—they can be the centerpiece of a family memory garden.

Start with a professional design. You may want to contract the task of creating a specific garden to a professional garden designer. If you do, tell the designer as much as you can about the site, and the style of garden you want. Make a list of favorite plants that you'd like included in your garden, and discuss it with your designer. Another alternative is to adapt an existing design and plant list to suit your site. For ideas, turn to the previous section, where you'll find designs for a color theme garden, butterfly garden, perennial herb garden, and many others.

Chart Your Plants

Making an organized plant list can seem like a chore. It's easier and more fun to circle plants that catch your eye in a catalog, or to scribble down a quick list of choices. But once you discipline yourself to make a formal list, you'll never regret it. An organized list—actually a chart—is invaluable when you design a garden. If you take time to record some basic facts about each plant, you can use it to evaluate your overall list of choices at a glance.

Continued ➔

To generate a plant chart you need graph paper and a clipboard, a pencil, a ruler, a 3 x 5 card, and a packet of colored pencils or markers. You'll also need reference materials, mail-order catalogs, and possibly a perennials encyclopedia.

First, write a very brief summary of the conditions at your site on the 3 x 5 card. A few words will do, such as "Dry shade" or "Full sun, hot, well-drained soil." Clip this card on your clipboard, sticking out from behind the graph paper. Each time you see a plant that appeals to you, check whether it will grow in the conditions you've listed. If it won't, put it on a wish list of plants for another site.

Line the graph paper and begin listing plants. Use colored pencils or markers to make the color bar that indicates bloom season and color. Don't worry if the bloom color isn't exact. You'll use it to make overall judgments, such as: Are there too many yellows and not enough pinks? Does anything on the list bloom in early fall?

In the "Comments" column, list the general shape of the plant first. Then note suggested combinations (many catalogs provide them), or notes about special care.

Once you've finished, evaluate your list. Start crossing plants off, eliminating ones with bloom seasons that are too short, foliage that isn't attractive for most of the season, or that aren't quite suited to the site. Also be sure you have a good assortment of heights and shapes. You may want to eliminate plants that need special care like staking or frequent division.

HOW MANY KINDS OF PLANTS?

Perennials need anywhere from 2 to 4 square feet of space per plant at maturity. So, to fill a 120-square-foot garden, you'll need between 30 and 60 plants. That doesn't mean you'll need 30 to 60 different species or cultivars; for an effective design, you'll want to plant drifts of some plants and repeating clumps of others throughout the garden to unify it. You probably actually need 15 to 30 different kinds of plants.

It's easy to let the collector's instinct take over and order one of everything. But you'll design a far better-looking garden if you steel yourself and limit your list. It's possible to have a fabulous-looking garden with only a handful of carefully chosen plants. And once you get your main perennials established, you can experiment with other plants that appeal to you.

Make a Planting Plan

Once your plant list is trimmed to size, it's time to turn it into a garden. To do that, you'll experiment with planting plans—arrangements on paper of your carefully chosen perennials.

Start by drawing your garden site to scale on a piece of graph paper. A good scale to start with is 1 inch equals 1 foot. For a large garden, you may need to try 1 inch equals 3 or 4 feet, or tape several sheets of graph paper together.

To position plants, begin drawing circles, ovals, or other shapes to represent clumps of plants. Start with one of the more important plants on your list—one that will provide color over a long season or that you want in a prominent place, for example. Then add others around it. Try to keep the shapes to scale. If you are planning a drift of a single perennial, be sure your bubble accommodates two, three, or more plants. It's easiest to number the plants on your list, and use the numbers (rather than writing out names) to identify each bubble on your diagram.

If you're designing a perennial border, draw the taller plants in the back and add layers of shorter plants in front. For an island bed, position the tallest plants in the center and add layers of shorter plants around them. For a formal rectangular garden, you may want to plant rows of a single plant along the edges with a contrasting plant in each corner. Here are some other tips to help you position plants and evaluate your design.

Plant in clumps. Design dramatic clumps of perennials, with three or more plants in each clump. A design filled with single plants will make an unsatisfying, spotty-looking garden with random bits of color here and there.

Repeat colors and textures. Place clumps of perennials with outstanding foliage or especially long bloom seasons throughout the garden. This helps unify the design and ensures you'll have attractive foliage and flowers to look at much of the time.

Move the color around. Arrange colors evenly throughout the site. If all your pink- or yellow-flowered plants are in one place, you'll end up with a lopsided garden.

Vary heights. Keep most of the tallest plants at the back (or in the center for an island bed), bringing a few forward a bit to create depth and variety. Bring some medium-height plants into the front row as well. Avoid a soldierlike lineup of plants of equal height.

Think season to season. Spread the bloom for each season through the whole border.

Try planting on centers. One technique that works effectively for meadow and prairielike gardens is to divide the site into 1-foot squares and plant a perennial or grass in each square. (Small plugs or 2½-inch pots are used for this technique.) Arrange the plants in drifts, with three, four, or more perennials planted in adjacent squares. Then let the plants spread and fill as they will.

Limit your plant list. If you run out of space on your plot plan before you run out of plants on your list, resist the temptation to squeeze in each and every plant. Instead, check the list of leftover plants against the plan. If some favorites are still on

the list, substitute them for a plant that's on the plan. After you double-check, set the list aside. Keep those leftover plants in mind for replacement possibilities in the event that ones you've selected don't grow as well as you had hoped.

Creating Woodland and Shade Gardens

Sally Roth

I've always liked surprises, and my woodland garden is full of them. Long before my perennial borders wake from winter slumber, I begin haunting the paths of my woodsy front yard. No wildflowers are chancing the weather yet, but the birds know spring is coming. This February morning, a pair of Carolina chickadees are courting, offering each other love songs in high, thin voices.

There's so much to watch in a woodland garden that the first wildflowers usually manage to take me by surprise. I know spring is here for sure when I come across a nosegay of dainty purple hepatica or a cluster of bloodroot flowers, their wide white stars held flat in the warmth of the sun. Once the wildflowers get going, there's something new every week. Watching them emerge from winter slumber into bud and bloom rejuvenates my spirit. As the flowers awake, the insects do, too. A humming noise leads me to a bevy of fat, slow bees bumbling about the pussy willows. They're right at nose level, but they're interested in pollen, not in me. At this height, it's easy to watch as they clean their dusty legs.

My woodland garden is so full of life that I sometimes forget what it looked like just a few short years ago. When we moved into our little log house, the front yard was a lovely sweep of green lawn beneath old oaks and elms. (And yes, they're American elms—this area seems to be one of the last bastions against Dutch elm disease.)

Most passersby would have said our front yard was pretty, and it was, in a parklike way. But to me, that green perfection was boring. Except for a scattering of robins and an oriole nest swinging from the tulip tree, I couldn't find much life to look at in my own front yard. The sunny side yard had plenty of room for playing ball with the dogs and catch with the kids. Who needed a front yard that was just for show?

The Making of a Woodland Garden

Little by little, I replaced the greensward with a woodland garden. I started with a single bed, smothering the grass with an ankle-deep layer of chopped leaves and putting in a few special plants from my local garden center. I tried to limit my choices to berried shrubs for the birds (though I splurged on a star magnolia, which the dogs promptly chewed off to a nubbin).

When October came around, I took advantage of the bounty of fallen leaves and chopped them into bits with a few passes of the lawn mower. Then I piled them into new beds along a tentative web of paths. When I liked the look of things, I moved in young trees and shrubs—redbuds, sugar maples, wild hydrangeas, viburnums, and my favorite, spicebush—from the natural woods behind our house.

In just a few short years, my woodland garden is looking like a real woods. Young oaks, maples, and hickories have sprouted in the blanket of humus, and wildflowers are multiplying happily. Last year I had a spread of self-sown, sky blue phacelia that rivaled my favorite wild spot down the road. The "exotic" plants I added—Japanese painted ferns, a few azaleas, and some favorite Oregon wildflowers—don't seem out of place here because I chose them to fit the feeling of the natural landscape.

The Nature of a Woods

In eastern Pennsylvania, where I grew up, the woodland was mostly deciduous trees (hardwoods), with occasional stands of hemlock, white pine, or spruce (softwoods) to add variety and contrast. In fall, the hillsides blazed with red and orange maples and the clear yellow of birches and tulip trees, accented by the deep green of the conifers. Because the trees and shrubs of the understory aren't dense and can be easily pushed aside if need be, you can enter an eastern woodland just about anywhere, whether or not there's a deer trail to guide your feet. In spring and summer, the air is rich and earthy with humus; in fall, there's a delicious crunch of dry leaves underfoot. Sunlight slants through the branches and beneath the canopy, creating patterns on the woodland floor.

Not until we moved to the Pacific Northwest did I find out that all woods are not created equal. The forests in Oregon are almost entirely coniferous, I was stunned to find, not to mention two or three times taller than eastern hardwood forests. Gigantic firs and spruces loom like somber giants, their branches interwoven to create a constant twilight on the forest floor. It's a good thing hiking trails are so common in the Northwest, because these woods are nearly impenetrable. The underbrush of wiry huckleberry, leathery-leaved salal, and waist-high ferns makes travel difficult except on paths. Instead of humus, the woods are aromatic with cedar and fir. Your footsteps are soundless on the thick, spongy carpet of needles.

Just about the time I got used to the deep, quiet cathedrals of the Northwest woods, we moved to southwestern Indiana—back to the hardwoods. We were so busy settling in and exploring our new surroundings (prairie flowers and grasses were a great distraction!) that it wasn't until my first Christmas in Indiana that I noticed that these woods, too, were different from my old Pennsylvania stomping grounds.

I like to cut my own greens for holiday decorations. But as I pulled on my boots that winter morning, I couldn't quite

Continued ➔

recollect where any evergreens were. Surely there must be a white pine in the woods behind our house, I thought, but after a morning of hiking, I found that everything was indeed deciduous. This was new to me, so I got in the car to reconnoiter on the gravel backroads that run through the farm fields. Whenever I saw a conifer on the horizon—and you can see for miles in this flat land—I'd head toward it. Each time, the pine or spruce turned out to be in someone's front yard. Oddly enough, our corner of Indiana is bereft of conifers, except for the deciduous bald cypresses that dot the river bottoms.

Shaking my head in wonderment, I ended up clipping boughs from a prickly eastern red cedar along the hedgerow, missing those soft Oregon firs and Pennsylvania pines more and more with every "Ouch!"

Woodland or Shade Garden?

I call my front yard a woodland garden because I intended it to look like a natural woods. A little disorganization is fine with me: After having set the garden's foundation in place, I'm letting the garden go pretty much where it wants to.

Like other natural gardens, creating your own woodland is a learning experience. In the first year, you'll lay out beds and paths and settle plants into place. You may fool yourself into thinking that's your garden. But someone else's ideas are always at work in a naturalistic woodland—the best gardener of all, Mother Nature.

At the head of my driveway is a more controlled planting, and that one I call a shade garden. Each plant is carefully chosen and placed in a design I planned for texture and all-season color. No one would ever call it formal, but it has a more groomed look than my woodland garden, where plants mix and match among a free-form blanket of leaves. My shade garden is an ornamental planting, but it has a lot to offer wildlife, too: Myrtle warblers feast on the waxy bayberries, bees and other insects visit the coltsfoot when it blooms in early spring, and native sparrows tug off pieces of dried ornamental grass for their nests.

In years past, a shady yard used to be something to complain about. Most gardeners have wised up, although even today, I still hear people talking about how they can't grow anything in the shade. More than once, I must admit, I've found myself grabbing them by the arm while I evangelize about the pleasures of a shady garden.

Whether your style leans toward a densely textured planting of quiet evergreens or a blatant copy of Mother Nature's grand scheme, you can create a beautiful natural landscape in the shade. In both shade and woodland gardens, you'll enjoy the play of color and texture, the song of wind through the branches, and the trilling calls of courting birds.

The Shady Side of Gardening

If you're dreaming of a woodland or shade garden, you probably already have some shade. Maybe the garage casts a daylong shadow along a strip that you've tried to brighten with impatiens. Maybe your front yard boasts a beautiful old maple, with roots so thick and thirsty that nothing grows beneath it. Or perhaps the street side of your place is bordered by a tall hedge or fence that shelters you from traffic but casts quite a shadow.

Not all shade is created equal. Under a grove of firs, the shade is deep and constant. In my former woodland garden in Oregon, beneath firs and spruces, the wildflowers are true shade-lovers, adapted to the all-season dimness beneath the evergreens. They included tall white fairybells, wide parasols of incredibly fragrant vanilla leaf, lacy tangles of rosy pink fumitory, and a carpet of wood sorrel.

Light is dimmed under an oak or Norway maple, too, but it's a seasonal effect. When the tree bares its branches come autumn, whatever is beneath it will be in the sun.

In springtime, when the warming rays of the sun reach through bare branches of oaks and poplars, my favorite wildflowers wake into bloom. These are the so-called spring ephemerals, like snow white bloodroot and creamy Dutchman's breeches, pink-tinged spring beauties and toothwort, and wild blue phlox and dwarf delphinium. These plants need sun to bloom and form flowers for next year, which is why they grow naturally in deciduous woodlands. By the time the trees' and shrubs' leaves grow in, throwing the garden into shade, the spring ephemerals have gone dormant until the next year.

One of the most unsettling sights I've ever seen was a spring woods in full bloom—in August. Hordes of gypsy moths had

Footpaths are a must in the old-growth forests of the Pacific Northwest, where giant conifers can top 300 feet and the understory is thick with a tangle of vine maple, ferns, and young trees. A carpet of fallen needles muffles every footfall and soaks up the soft rain like a sponge.

Hardwood trees like these paper birches make a deciduous forest glow with glorious color in autumn. Common in northern forests from Alaska to Maine, they were "canoe birch" to Native Americans, who sewed the strong white bark over frames of cedar for their watercraft.

completely defoliated the trees, and when the sunlight reached the forest floor, it woke the spring ephemerals. Rose-breasted grosbeaks and wood warblers were moving through the trees in their drab fall plumage, while beneath them bloodroot was blooming and mayapple was pushing up. It was downright weird.

The quality of shade, as well as its season, also varies. Beneath alders or birches, shade is dappled, with sunlight glancing through the leaves to speckle the ground in changing patterns. In the shadow of a garage or a neighboring building, however, shade is solid and unchanging.

If you're the type of person who loves details, you can keep a calendar that charts when your planned garden spot is in sun or shadow. And you can think about how the shade changes through the seasons, as the sun charts a higher or lower course through the sky.

A spot that gets morning sun in high summer, when the sun is northward and nearly overhead, may be in shade all day in autumn, when the sun slinks along close to the horizon. And vice versa, of course.

When you're planning a shade garden, there's no need to spend a year measuring the way the light shifts. Summer sun is the important factor. That's when the earth is tilted toward old Sol and the rays are most intense. Site your shade garden so that

Shade Garden or Woodland Garden?

The line between shade and woodland gardens is easily blurred, but there are distinctions that make your garden a shade garden as opposed to a woodland garden or vice versa. These general ideas will help you decide which direction is right for you.

Shade Garden

- Can be created in a small or large space. Even a 2-foot-wide strip can be made into an appealing shade garden.
- Is generally more controlled in look and feel, although the degree of control is up to you.
- Usually consists of low-growing, low-maintenance plants, including lots of groundcovers and evergreens, so it looks good and green year-round.
- Is in shade almost all the time, in every season.
- Can be created anywhere you have part or full shade: where a tree or a building casts a shadow, between your house and your neighbor's, or on the north side of your home.
- Includes more "exotic" plants that wouldn't naturally grow in your area.
- Attracts birds and small mammals seeking food and shelter.

Woodland Garden

- Needs plenty of elbowroom to look natural. Fifty square feet is about the minimum, although you might create a strip of woodland garden (10 x 30 feet or more) along a walk or drive.
- Is more naturalistic in look and feel. At its finest, it looks like a piece of natural woods transplanted to your yard.
- Has a seasonal look that mirrors the natural woodland of your area.
- May change in sun or shade exposure, depending on the season.
- Needs trees for an underpinning. If your yard is graced by shade trees, or even a single good-size tree, you have the perfect foundation for a woodland garden. If you don't already have trees, you can add them.
- Includes many native species, but can also be rounded out with ornamentals that maintain the effect.
- Attracts nesting birds and mammals.

Continued →

it will be out of the reach of the hot summer sun when it's at its peak, from 10 A.M. to 2 P.M.

But unless you're new to the neighborhood, chances are you already know where and when the shade falls in your yard. That's where you hang the hammock in summer, where you can't grow vegetables or grass, or where the last bit of snow lingers.

Shade-loving plants are adapted to lower levels of light. Their foliage will burn in the sun, and their growth will suffer if the sun is too direct or lasts too long. But except for a few absolute "shademasters," most shade-loving plants will adapt to partial shade as long as they're protected from the most brutal rays of the sun.

Shady soils can be moist or dry, just like those in other parts of the garden. Tree roots can soak up an enormous amount of moisture, especially if it's been a while since the last rain—even an inch of rainfall can leave the soil under a tree barely moist after the roots wick it away. And where rainfall is scarce, the soil may be bone-dry. You can handle dry shade in several ways: Choose plants that will thrive in dry, shady conditions; use mulches to help slow evaporation; and dig in organic matter to help your soil retain more water. Columbines, hostas, impatiens, and astilbe all prefer moist soil, but many shade-lovers will thrive in dry conditions. Try stout, spiny bear's breeches (*Acanthus mollis*), tall, blue American bellflower (*Campanula americana*), fringed bleeding heart (*Dicentra eximia*), the invasive but beautiful plume poppy (*Macleaya cordata*), and two hellebores, Corsican and fetid (*Helleborus lividus* var. *corsicus* and *H. foetidus*).

Start with Structure

Once you have your shady site picked out, it's time to do a little planning. As with any garden, you'll want to start by laying out the basic structure.

Paths in any garden are a major part of the garden framework, and they're what I always start with. Then I plan for height and "hardscape" elements like walls and structures, the other things that give a garden some backbone. The last thing I do is plant evergreens to help the garden hold its shape in winter.

In my Indiana woodland garden, once I had an idea where the paths would go, I started planning the understory. I didn't want the three old shade trees to stick out like sore thumbs. I needed to step them down with a second layer of shorter trees, to provide a transition between the shade trees and lower-growing plants.

ADDING AN UNDERSTORY

The layer of shorter trees and shrubs that surround mature trees in a natural woods is called the understory, and it's a vital part of a woodland—and a woodland garden. Many understory trees are actually understudies—youngsters of the dominant forest species that come into their own when an old patriarch keels over, creating an opening for more sun. These trees typically grow tall and spare, concentrating their energy on pushing upward toward the sun, not on growing side branches.

The more attractive understory plants for a woodland garden are shade-tolerant, midheight species that will grow and branch normally, even in the shadows. There are plenty of good choices, from eastern deciduous woodland natives like American persimmon and eastern redbud, to western species such as vine maple and Pacific yew, to foreign, shade-tolerant species, including China's golden-rain tree, the signature tree of the former Utopian community here at New Harmony and one of my favorites for landscaping.

The easiest way to choose understory trees for a woodland garden is to spend an afternoon looking at different stretches of nearby woods. The first thing you'll notice is that much of the understory is made up of youngsters—10-, 20-, or 30-year-old trees waiting to take the place of their elders. But you'll find lots of midheight possibilities, too.

In our Indiana woods, I jotted down my favorites: persimmon, sassafras, redbud, dogwood, Kentucky coffee tree, and blue beech. If you don't know the names of your local trees, take a field guide with you, or collect leaves to identify later.

Beneath the layer of midheight trees come shrubs of all sizes, including those that cross the line to small tree status, such as fringetree and spicebush. I always run out of space long before I run out of possibilities—there are so many good choices, it's hard to stay focused. Choose those that personally appeal to you, but try for a mix of fall foliage, flowering, and evergreen plants, while keeping an eye out for those with good winter form. If a plant incorporates more than one good trait, hallelujah.

Between and beneath the shrubs go the herbaceous plants: perennials, annuals, ferns, and groundcovers. I don't mind admitting that I blatantly copy many of my planting combinations directly from Mother Nature. When I saw a patch of white violets mingling with pale blue Jacob's ladder, punctuated by spikes of blue camas lilies and surrounded by a ruff of spring green fragile ferns, I claimed the combination for my own and went home to order the plants from my stash of specialty catalogs. If it works in the wild, it will usually work in your garden, as long as you can offer the plants similar conditions.

Grow Your Own Trees

As you stroll the paths of your woodland or shade garden in spring, watch for the first unfolding leaves of baby trees. Even if there's no nearby natural woods, seedlings will sprout in your woodland garden from berries or seeds brought in by birds or on the wind or from nuts and acorns buried by squirrels.

Not only is it fascinating to watch the first tiny growth spurts of a tree, but it's also a good way to add to your garden. Try to leave the young seedling in place; it will grow faster and sturdier if its roots aren't interrupted. If you must move it, transplant

as soon as possible and take a giant-size scoop of earth with the seedling to avoid disturbance.

In just four years, my woodland garden had sprouted an impromptu nursery of sugar maples, tulip trees, elms, beeches, hickories, four kinds of oaks, sassafras, wild cherries, hackberries, redbuds, dogwoods, and even two prized hawthorns—not one of them planted by me.

It sounds like such a bonanza would overwhelm the garden, but I've found that the young trees take care of themselves. Many of them die out naturally. Others grow so vigorously you can't believe it. Did you know that a two-year-old tulip tree can reach 4 feet tall? One of my three-year-old redbuds is taller than me.

It's incredibly satisfying to watch a tree grow from a seedling sprout to a sturdy specimen. I appreciate my garden-center trees well enough, but I have a definite fondness for the trees I watched sprout their first leaves.

Foliage Favorites

Designing a garden for a shady site will quickly move your focus from flowers to foliage. Though there are plenty of flowers that bloom in shade—lamiums, hellebores, and American bellflower are three of my favorites—much of the show is carried by the foliage of the plants you choose for your garden.

Except for a cherished planting of golden hakone grass, my shade-garden colors are pretty much basic green during the growing season. Autumn brings wonderful warm colors from shrubs and perennials and long-lasting impact from the miscanthus, spodiopogon, and other ornamental grasses, which mellow to tan and beige. Groundcover conifers acquire a tinge of red, gold, or silver with cold weather and shorter days.

I've learned that when I stick to a plain green color scheme, I can concentrate on textural effect rather than on color. My shade garden is like a needlepoint tapestry—it's rich with variations in color and texture, but they blend together into a cohesive whole.

In my shade garden, I use ground-hugging plants like bearberry and European wild ginger to add a change of height and some gloss to the planting. Because I want the shade garden to look good year-round, I use a lot of evergreen groundcovers in it.

In my woodland garden, I plant more casual groundcovers, including deciduous types. I like the spiky texture that white foamflower adds, and I choose the running type not the ones that stay in neat clumps.

I discovered one of my favorite groundcovers by accident. On one side of my woodland garden, where hardy geraniums bloom in spring, a vine of Virginia creeper sprouted from a seed probably brought in by birds. I had no place for the vine to climb, so I let it creep—and that's what it does best. Its interesting, five-part leaves provide greenery through spring and summer, but in fall they literally shine. The foliage turns brilliant red and crimson, winding through my garden like a river of fire. As a bonus, mature vines bear deep blue berries that are eagerly sought by downy woodpeckers.

FABULOUS FERNS

Ferns add a lush touch to a shady garden, even if you plant just a single clump. Beware of where you buy them, though—some unscrupulous suppliers dig them up from the wild to sell. If I'm ever tempted by the often bargain-basement prices of wild-collected stock, I think about what was destroyed so somebody

Woodland Garden Design

Create a shady haven with a combination of shrubs, trees, and perennials that offer structure and beauty year-round.

Many of the plants in this garden offer colorful flowers as well as richly textured foliage. This garden offers all-season beauty, from earliest spring, when the star magnolias burst into bloom, to the glories of fall, when your shady spot will be glowing gold and orange.

In winter, the graceful forms of the deciduous shrubs and the weight of evergreens will give it structure until the seasons roll around again and the warming sun coaxes the ephemeral spring wildflowers into bloom.

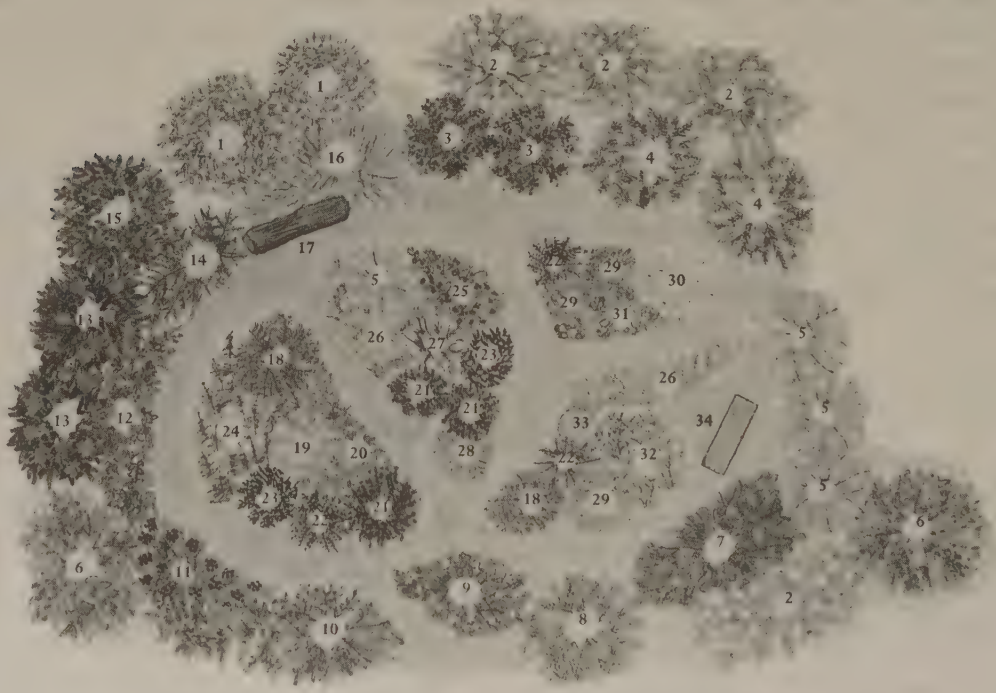
Plant List

1. Deodar cedar (*Cedrus deodara*)
2. Flowering dogwood (*Cornus florida*)
3. American holly (*Ilex opaca*)
4. Hemlocks (*Tsuga canadensis*)
5. Spicebushes (*Lindera benzoin*)
6. Existing deciduous shade tree
7. Hazel (*Corylus avellana*)
8. Eastern white pine (*Pinus strobus*)
9. Thimbleberry (*Rubus parviflorus*)
10. Serviceberry (*Amelanchier laevis*)
11. Lowbush blueberry (*Vaccinium angustifolium*)
12. Waterleaf (*Hydrophyllum macrophyllum* or *H. canadense*)
13. Rhododendrons (*Rhododendron* spp.)
14. Beaded woodferns (*Dryopteris bissetiana*)

Continued ➔

15. Yellow birch (*Betula lutea*)
16. Heathers and heaths (*Calluna* and *Erica* spp.)
17. Log bench
18. Orange-flowered witch hazel (*Hamamelis* x *intermedia* 'Diane', 'Orange Beauty', or 'Copper Beauty')
19. American persimmons (*Diospyros virginiana*)
20. Virginia creeper (*Parthenocissus quinquefolia*)
21. Winterberry (*Ilex verticillata*)
22. Christmas ferns (*Polystichum acrostichoides*)
23. Black pussywillow (*Salix gracilistyla* var. *melanostachys*)
24. American bellflowers (*Campanula americana*)
25. Hearts-a-bustin' (*Euonymus americanus*)
26. Bottlebrush grass and fall Japanese anemone (*Hystrix patula* and *Anemone japonica*)
27. Dead tree
28. Golden hakone grass (*Hakonechloa macra* 'Aureola')
29. Whippoorwill azaleas (*Rhododendron periclymenoides*)
30. Star magnolias (*Magnolia stellata*)
31. Dutchman's breeches and bloodroot (*Dicentra cucullaria* and *Sanguinaria canadensis*)
32. Japanese painted ferns (*Athyrium goeringianum* 'Pictum')
33. Pottery birdbath (basin only) set on a rock
34. Bench

Note: All shrubs and planting areas can be underplanted with spring ephemeral wildflowers, such as wood anemone, rue anemone, mertensia, erythroniums, mayapple, Jack-in-the-pulpit, bloodroot, and others.



could make money from it. Unless it says "nursery propagated," I don't buy it.

My friend Bill was transplanted to a new house after 70 years in the old one, and though he tried to make up for lost time, he never could re-create the gardens he'd worked on for half a century. What he missed most of all, he often said, was the fern grotto. Delicate, black-stemmed maidenhair ferns sprang from cracks in the granite, he told me, and misted like an angel's hair when the water sprayed over the rock. He planted maidenhair above a small pool at the new place, but it didn't have the same magic for Bill.

I thought the new planting was beautiful. Bill's ferns thrived above the water as if they'd always grown there. In my heart, I wondered what it was that he was really missing. Was it his position? His fortune? His youth?

It wasn't until years later that I found out just what Bill had given up. I was hiking along a spongy-soft trail in a stand of hemlocks when I came upon a real fern grotto. It was so beautiful that I fell to my knees without thinking, in absolute awe of such grace. Silvered with a fine mist, the rippling tresses of maidenhair fern bowed from every crevice in the wet rock wall. A fine thread of icy water dropped to a pool below, its

Can't-Fail Ferns

The ferns listed here will thrive in the shade in rich, moist, well-drained soil. Many other species and varieties are available, but these are among the easiest to grow.

To keep your ferns happy, mulch them well with chopped leaves and let fallen autumn leaves remain in place. The emerging fronds have a lot of lift power. In spring the new fiddleheads will push up right through last year's leaves.

Beaded wood fern (*Dryopteris bissetiana*). This unusual fern has dark green, leathery, 1- to 2-foot-tall fronds that are divided into round segments, which give the plant a beaded appearance. The arching fronds stay green all winter; the plant doesn't send up new fronds until summer. USDA Plant Hardiness Zones 5 to 8.

Christmas fern (*Polystichum acrostichoides*). Common throughout eastern North America, this classic evergreen fern settles easily into the garden. The clump of deep green, leathery fronds stays fresh all winter. Early settlers supposedly used it for Christmas decoration, but I find that the fronds dry out and curl soon after picking. Zones 3 to 9.

Cinnamon fern (*Osmunda cinnamomea*). Mighty clumps of 3- to 5-foot-tall fronds surround upright spikes of bright cinnamon-color fertile fronds. This plant makes a great punctuation mark with groundcovers or among perennials, and it makes red-orange or white impatiens look new again. In autumn, cinnamon fern turns a rich, rusty brown color. Zones 2 to 10.

Fragile fern (*Cystopteris fragilis*). This little charmer usually stays under 12 inches tall and may not even clear 6 inches. It unrolls its tiny fiddleheads very early in the season and is beautiful with ephemeral spring wildflowers. The lacy fronds are a clear spring green and go dormant by summer. Fragile fern spreads into colonies but is never a pest. Zones 2 to 9.

Hay-scented fern (*Dennstaedtia punctiloba*). This airy fern grows in light shade or sun; it's a good one to plant where woodland garden meets lawn. It spreads rapidly by creeping roots to form large colonies. Brush against the delicate fronds, and you'll smell the wonderful fragrance of newly mown hay. In fall, it turns soft primrose yellow. Zones 3 to 8.

Japanese painted fern (*Athyrium goeringianum* 'Pictum'). This is the showgirl of the big lady fern genus. She comes tarted up with silver and burgundy, but it's a wonderful effect in a shady garden. The clump of 1- to 2-foot fronds can expand to bushel-basket size in moist, rich soil. Just slice through it with a spade to multiply your collection. Zones 4 to 9.

Lady fern (*Athyrium angustum*, *A. asplenioides*, and *A. filix-femina*). The first two lady fern species named are native to America; the last is from Europe. All grow in a clump of fresh, medium green, erect fronds that grow 18 to 30 inches tall. "Crested" forms of European lady fern are much in vogue among fern fanciers; their fronds are sometimes so distorted that they look like curly parsley. I prefer the species *A. angustum*, Zones 2 to 8; *A. asplenioides*, Zones 4 to 9; *A. filix-femina*, Zones 4 to 8.

Maidenhair ferns (*Adiantum pedatum*, *A. aleuticum*). Native to eastern and western North America, these delicate ferns have fronds that radiate from a crescent-shaped axis at the top of a bare, blackish stem. Maidenhair fern gradually expands into a colony and looks beautiful on a slope, where its Rapunzel effect can be best appreciated. Zones 2 to 8.

Sensitive fern (*Onoclea sensibilis*). This was the first fern I knew, which is probably why I'm still partial to it. It is widespread in the eastern half of the country. It spreads like crazy, which can be an asset or not, depending on where you put it. Keep in mind that it will swamp all but the most stalwart plants. If you're tired of pachysandra, add this fern to the planting—they look great together. Fronds have wide segments, giving the plant a bolder appearance than the typical "ferny" fern. Sensitive fern turns brown in autumn. Zones 2 to 10.

Continued →

depths so clear that I shook my head to try to clear my eyesight when a ripple spread across.

Maidenhair fern looks as ethereal as its name, but it's as tough as forsythia. Many other beautiful ferns will also adjust easily to life in a shade garden. If you've never explored the world of ferns, a shade garden is a great excuse to dig in.

Finishing Touches for Your Woodland Garden

For most gardeners, the finishing touches in a shade or woodland garden would be paths, benches, and the like. But for me, they're the first step—part of the essential bones of the garden. My finishing touches are mushrooms, moss, and other materials that make the garden seem real. But luring these humble plants into your yard isn't as easy as you might think.

THE MARVEL OF MUSHROOMS

When I was a kid, I used to try to plant flowers. Literally, I mean. I'd stick dandelions and roses and whatever else I could find into the soil stem first. Naturally, lacking roots, every one died.

It's just as useless trying to transplant a mushroom. No matter how big a scoop of earth you take, you won't come close to collecting all of the many miles of the nutrient-gathering mycelial threads that keep the mushroom alive. A mushroom is only the "flower" of the fungus; it sprouts to spread spores for reproduction.

You can try collecting mushrooms for sowing spores (though I've never had any luck at it). Or you can just wait and see what comes up naturally. Shaggy mane mushrooms sprout every year in my front yard.

One of my favorite fungi sprouts liberally in my wood-chip paths. It's the tiny bird's-nest fungus, a ¼-inch cup that holds minute brown "eggs." I like to put the "nests" into plastic specimen boxes with a tight-fitting, magnifying lid as a quick gift for young friends.

MOSS MAKES YOUR WOODS LOOK OLD

Moss is a lot easier to move into the garden, but, like fungi, it will often appear spontaneously if conditions are right. You can move small pieces of moss from other places on your property and press them into bare soil or on moist, decaying logs. Or you can buy a bag of prepared "moss bits" from a commercial supplier and follow the instructions for sowing. Don't decimate a natural spread of moss in the wild. Mosses are slow-growing plants, and it takes them many years to recover from even one afternoon's thoughtless collecting.

THE VALUE OF DEADWOOD

Collecting the final finishing touch, deadwood, can become habit-forming. Deadwood may not sound too appealing at first, but it's a great way to give your woodland garden structure and make it more appealing to wildlife.

Dead trees are prized by woodpeckers, and they make a fine foundation for a feeding area. You can smear peanut butter on them, wire suet to them, or hang feeders from them. A dead tree is also a favorite perch for birds approaching the feeder.

You say you have no dead tree? No problem. You can make one.

Unless your nickname is Samson, you're probably going to have more luck erecting a dead limb than an entire dead tree. Here's how to do it:

1. Choose a limb at least 4 inches thick and at least 6 feet tall. Stab a fingernail into it to make sure the wood is firm, not decayed.
2. For a short-term, one- or two-season "tree," simply plant your limb into the soil. Dig a hole at least a foot deep (deepen the hole if the "tree" is taller), insert the thick end of the limb, and firm up the soil around it.
3. For a longer-lasting "tree," you can fill the hole with quick-setting concrete before you "plant." Mound the concrete around the limb so that it slopes downward, allowing water to drain quickly. But keep in mind that when the tree eventually falls, you'll be left with a block of concrete in the ground.

As with any dead tree, you'll want to avoid getting beaned if the thing topples. I give my dead "trees" an occasional medium-force push every now and then to make sure they're still standing firm.

Logs, stumps, and even sizable branches are heavy and awkward and hard on the back. Don't take on more than you can carry. Enlist a friend to share the labor. I sometimes amaze myself by balancing such heavy objects across my old metal wheelbarrow, holding them in place with a hoe, and finagling the barrow through the garden. But I don't recommend this procedure.

Deadwood is just as useful lying down as it is standing up, and it's often more decorative. An interesting log or branch can add a very artistic touch to a shade garden or that final bit of realism to the woodland garden. Add a good-size log (8 inches or better) to your woodland garden, and you hand an invitation to all kinds of interesting creatures. Fascinating click beetles, which pop and flip in your hand like Mexican jumping beans, will work on and below the bark. Engraving beetles will mark the trunk with hieroglyphics, and wood-boring beetles of all kinds will work on the wood. After bugs come birds, especially woodpeckers.

A log or stump also offers shelter for animals beneath it. When I dragged a toppled aspen into a previous garden, settling it between a couple of thickets of berry bushes, a cottontail rabbit dug a warren beneath it in less than a week. The stump in my current garden sheltered a cottontail this year, too. Actually, it sheltered six of them. If I lean down and peek at just the right angle, I can still see the soft bowl of grasses and fur that was their

nursery. Mice and other small mammals will also make use of a fallen log. So will toads, salamanders, snakes, and lizards.

Another interesting character that may show up to investigate your deadwood is a skunk. Skunks are interested in the grubs that hide in the decaying wood, and like woodpeckers, they're adept at digging them out. Don't fret if a skunk turns up in your garden. If you treat it with plenty of respect and give it a wide berth, it will have no reason to spray.

I've appreciated skunks ever since one helped me out by excavating and destroying a colony of yellowjackets that had moved into my garden. I saw him sniffing near the wasps' nest-hole in the moonlight one night, and the next morning, the paper hive was strewn around the yard and nothing was left of the nest but an empty crater. I still don't know how he avoided getting stung.

Wildlife in Woodland Gardens

Deadwood isn't the only thing that will attract wildlife to your shady gardens. They'll also come to seek fruit, berries, nuts, and other foods and to seek shelter. Shrubs with berries and trees that bear nuts or acorns will draw birds and small mammals. Insects will move in to seek a niche and so will the creatures that eat them: mice, moles, voles, shrews, and other small furry types. Hawks and owls may scout your gardens hoping to catch the rodents unawares.

An unexpected bonus of my woodland garden is that it swiftly became a corridor of safety for the birds that live in the real woods several hundred yards away. Towhees, rose-breasted grosbeaks, and scarlet tanagers now feel comfortable visiting my feeders, and wood thrushes and veeries scratch about in the leaf litter of my woodland garden. Vireos and wood warblers move from the tall sugar maples in the woods to the young redbuds and spicebushes in the garden, gleaning insects from the foliage. If there were less human and canine traffic in the garden, I have no doubt these birds would come to nest as well as dine.

Seasonal Pleasures

A shade or woodland garden is a wonderful respite from the summer sun. Even the dogs seek a haven there in summer, flopping on their sides beneath a favorite bush.

But it's a pleasure through all of the other seasons, too. In autumn, after the asters and goldenrod have finished the season in the meadow garden, my woodland garden is still a place of unexpected delights. Berries of spicebush and hollies ripen into shining red, as polished as the bowl of apples on my kitchen table. Leaves blaze with color, then sift down from the canopy into a wonderful crunchy blanket that's as much fun to kick through now as when I was a kid.

By the time winter settles in, chickadees, titmice, nuthatches, white-throated sparrows, and dozens of other birds have taken over the garden, gleaning the last seeds and berries, scratching aside the leaves, and scouring bark and branches for insects. Their quiet chips and call notes sound like a conversation among friends. There's always life and motion outside my window, even on the dreariest days (especially on the dreariest days—that's when the birds really come to forage). And snow in a woodland is one of nature's most beautiful sights. What a difference from a few years ago, when all I had to look out upon was a boring expanse of perfect grass.

Creating Water and Bog Gardens

Sally Roth

Water makes a garden a special place. Being around water, whether it's a pond, a brook, an ocean, or a fountain, refreshes and energizes us. Looking into water inspires both serious contemplation and idle daydreaming. And when you have water, you'll have all kinds of surprises. You may see regal great blue herons, slick-furred muskrats, iridescent dragonflies that flit about like living jewels, lotuses with flower centers that dry into huge salt-shaker pods, frogs perched on lily pads just like in cartoons—and that's just above the water.

Surface tension creates a thin film of water that is truly walkable, if you have the right equipment. Look on for water striders, which skate about like long-legged spiders, or whirligig beetles, which zip around in circles too fast for human eyes to follow. Catch one in a paper cup for a close-up look.

The submerged world holds even more curiosities. Turn over a few rocks in a streambed, and you'll get an inkling of what sorts of oddballs await in the water world. One summer, I enjoyed myself thoroughly introducing my sophisticated, well-traveled neighbor to the weirdos underwater. We crouched in the shallows, examining the primitive-looking, spike-tailed insects flattened beneath every rock. We fished out the vicious giant-jawed creatures that turn into jeweled dragonflies. And we peered at naked caddis-fly larvae hiding inside portable homes of cemented debris. Even in Rome, said my worldly neighbor, he'd never seen anything to match this gallery.

Water also brings all kinds of gardening opportunities. Now you can consider wonderful water-loving plants, from classic water lilies opening their waxen cups to the sun, to tiny white flowers of starwort (*Callitriche hermaphroditica*) spangling the water like a handful of stars, to the striking lances of golden club poking up from cool, blue-green leaves. You can plant stalwart yellow and blue flag irises that wave like French banners, or you can indulge in extravagant Japanese irises, which grow to huge, ruffled perfection in boggy places. Before you know it, you'll be wishing for more space in your water garden, just as you do in your perennial borders.

Continued ➔

I've been lucky enough to have natural water at or near every place I've lived, so I've never had to excavate for a pond. But I've lent my back and my advice to friends putting in ponds, pools, and fountains, and I've seen the transformation that water can work on a garden. It's magic!

Water Music

A still pool offers serenity and multiplies the impact of plants and sky reflected in its mirrored surface. But it's water music that brings a garden alive. The quiet burble of a fountain, the splash as water spills over a rock ledge, a silver thread of water tinkling into a fern-lined pool—our eyes follow our ears to the sound, and we are drawn to water as instinctively as any bird or other wild creature is.

Before you reach for that shovel, though, think about what qualities of a water garden are most important to you. Start by thinking about the water itself. A quiet pool has a much different personality from a rippling brook. If the sound of water is important to you, you'll want to add a small fountain or a recirculating stream. Or you can allow one side of the pool to lead off to a short drop, where falling water will play its music. If you opt for a fountain, there's a wide variety of possible effects, from a gentle shower to an arching spray to a thin trickle.

Besides the ephemeral pleasures of water music, there are more tangible aspects to consider, too. The kinds of plants we think of as typical water-garden plants—water lilies, lotuses, pickerelweed, and many others—thrive in still waters. You'll need a pool or pond area for these to do well.

Look at the lay of your land, too, when you're planning a place for a water feature. If you have a slight slope, that's a natural beginning for a waterfall or handmade stream. A recirculating pump and buried tubing will carry the water back to the starting point.

The size of your garden or yard is another thing to keep in mind. Of course you can't dig a huge farm pond in a typical subdivision or on a city street. But a small pond can fit in any garden.

Water Garden Visitors

If you build it, they will come. Birds, animals, bugs, and butterflies, that is. The traffic at your birdbath is nothing compared to the visitors you'll see at a pond. I love to check the guest register in the soft mud at the edge of the pond. Because many of your visitors will come in the night, you'll soon want to add a field guide to animal tracks to your collection. I look for the perfect pairs of half-moon deer prints, the wide-spread stars of skunk feet, the thumbed handprints of raccoons, and the big, turkey-like marks and white-lime splashes of herons.

It's a toss-up between frogs and birds as to who will find your water first. When my children were toddlers, a frog often moved into their shallow inflatable swimming pool overnight! But frogs aren't nearly as plentiful today as they were ten years ago, for reasons that aren't clear yet but may have a lot to do with ozone depletion. Frogs may still move into your pond quickly, usually within a few weeks, but chances are that your first visitors will be birds. A reliable source of clean, fresh water is a powerful draw for songbirds, especially if the area is planted with sheltering grasses and shrubs.

I love to watch birds reveling in their baths. Robins, goldfinches, blackbirds, native sparrows, and bluebirds are

Best Trees for Woodland Gardens

Trees	Description	Conditions	Comments
Flowering dogwood (*Cornus florida*)	Small tree with graceful layered habit and beautiful white or pink flowers in spring. Reaches to 10'.	Partial or light shade. Moisture-retentive, organic soil. Zones 5 to 9.	Unfortunately susceptible to fast-spreading dogwood blight; call your extension agent about the extent of the problem in your area before planting.
Oaks (*Quercus* spp.)	Many species of medium- to large-size trees, all bearing acorns. Grows 100' or more.	Partial to full shade. Zones 3 to 9, depending on species.	Many oaks are widely adaptable, but it's fun to get to know your native oaks, like white oak and red oak in the East, Midwest, and North; Gambel oak in the intermountain states; and blackjack oak in the Southeast.
Redbuds (*Cercis* spp.)	Small trees with tiny pink or white blossoms thickly studded along the branches before the leaves appear in early spring. Reaches to 40'.	Partial to light shade. Average, well-drained soil. Hardy to Zones 5 to 8, depending on species.	Redbuds are ideal for planting under tall shade trees. Eastern redbud (*C. canadensis*) is a trouble-free small tree, hardy to Zone 5. In the West, try Western redbud (*C. occidentalis*), a shrubby, multitrunked species with excellent drought tolerance, hardy to Zones 8 to 9.
Spruces (*Picea* spp.)	Large, evergreen conifers with dense, short, stiff needles. Reaches to 150'.	Sun to partial shade. Average, well-drained soil. Zones 2 to 4.	Spruces have dense branches that make excellent protection from the elements for birds. Norway spruce (*P. abies*) and Colorado spruce (*P. pungens*) are widely adaptable.
Sugar maple (*Acer saccharum*)	Large tree with graceful form and superb orange and gold fall color. Reaches to 130'.	Sun to light shade. Rich, moist, organic soil. Zones 3 to 5.	Excellent shade tree. Outstanding red, yellow, and orange fall color, even on young seedlings.

Best Shrubs for Woodland Gardens

Shrubs	Description	Conditions	Comments
Flame azalea (*Rhododendron calendulaceum*) and pinxterbloom azalea (*R. periclymenoides*)	Deciduous native azaleas with loose clusters of pink or white (pinxter) or red, orange, or yellow (flame) flowers in spring reaches to 9'.	Partial to full shade. Rich, moist, acid soil. Flame azalea, Zone 5. Pinxterbloom azelea, Zones 4 to 8.	These adaptable eastern natives are like manna to hummingbirds. Pinxterbloom azalea flowers are wonderfully fragrant, while flame azalea offers vivid, unusual flower color.
Hearts-a-bustin' (*Euonymus americanus*)	Deciduous shrub to 8' with intriguing fruit capsules that split open when ripe in fall, revealing the red "heart" inside. Excellent fall color. Reaches to 5'.	Partial to moderate shade. Average garden soil. Zones 6 to 9.	This relative of the common landscape shrub burning bush is a quieter presence in the garden, though it still offers brilliant crimson fall color as well as decorative fruits appreciated by birds.
Pussy willow (*Salix discolor*)	Deciduous shrubs with charming furred catkins in spring, before the leaves emerge. Reaches to 20'.	Sun to partial or moderate shade. Average soil. Also thrives in wet soil. Zones 4 to 9.	Good for early foraging honeybees. A favorite for coaxing a bouquet in late winter.
Spicebush (*Lindera benzoin*)	Graceful, open, deciduous shrub with attractive form. Dark-barked branches are studded with tiny yellow blooms in very early spring. Reaches 4-15'.	Partial to full shade. Average soil. Also thrives in wet soil. Zones 4 to 10.	An underused American native. All parts have a pleasant spicy fragrance. Red oval berries are a favorite of thrushes and don't last long on the bush.
Thimbleberry (*Rubus parviflorus*)	Deciduous shrub with maplelike leaves, white flowers in spring, and red raspberrylike fruit in summer. Reaches to 6'.	Partial to moderate shade. Humus-rich acid soil, but also adapts to average soil. Zones 4 to 9.	Shredding bark adds to winter appeal. The similar purple-flowering raspberry (*R. odoratus*) is also good for the woodland garden.

especially fond of bathing, but I have also been privileged to spy on evening grosbeaks, cardinals, chickadees, warblers, and, once, a scarlet tanager at the bath. But even starlings and English sparrows are fun to watch as they go through the motions.

At first they duck their heads tentatively, but before long, they're thrashing about with fluttering wings, as uninhibited as a toddler in the tub. When the bird is thoroughly soaked and looking as pathetic as a wet cat, it'll look for a place to preen and perch out of harm's way while its feathers fluff and dry. On a hot, dusty summer day, you know how good that bath must feel. But they'll also bathe in weather so chilly that brittle ice decorates the water's edge. It makes me shiver just to see them, even if I'm watching through a window.

Container Water Gardens

It's amazing how satisfying even a tiny water garden can be. If you only have room for one plant, grow a water lily. They may seem pricey when you compare the cost to perennials, but even the most common types are exquisite. A single water lily, partnered with a glimpse of dark, shining water, is a delight to the soul.

When space and time (not to mention money) were really tight one summer, I made a water garden in a big plastic tub—one of those "muck buckets" sold at discount stores. I chose a black tub, which looked surprisingly good when filled with graceful rushes, a single pink water lily, and the wonderful textures of water lettuce and ferny milfoil. (I can't resist those rosettes of ruffled, pleated water-lettuce leaves.)

My tub wasn't ultraviolet (UV)-light resistant, and it only held up for three years before the UV rays degraded the plastic and leaks appeared. But then again, it only cost $7. Large, sturdy, UV-resistant plastic tubs and pots are now made in appealing shapes and matte finishes and are widely available at garden centers. Or you can go the cheapskate route like I did and shop the housewares department.

Some gardeners use oak half-barrels, lined or unlined. I tried filling a half-barrel with water without using a liner, hoping the staves would swell and stop any leaks. It was a little tricky keeping the metal barrel bands evenly horizontal as the wood expanded, and the wood never became totally watertight, but the barrel did hold water. My half-barrel never did become a successful water garden, unfortunately, because my dogs claimed it as their own watering hole. After a few weeks of mourning over broken stems and damaged plants, I gave up on the water garden and let the dogs have their way. But I did get a nice bog garden out of it, thanks to the constant slopping of water over the edge of the tub and the slow leakage through the staves. Around the barrel's muddy base, moisture-loving plants, including forget-me-nots and even watercress, grew in beautiful profusion.

Tubs and pots are heavy enough even before adding water, so decide on the location of your container water garden before you move it into position. A sunny spot is good for water lilies, but a partly shaded site will cut down on evaporation and algae. You'll need to collect a few flat stones or bricks to help boost plant pots to proper height inside the tub. I like to perch a rock in my container water garden as a sipping spot for birds or a landing pad for dragonflies. I set it on top of a submerged piece of clay drainage pipe so that the surface of the rock breaks the water but the underpinnings aren't exposed.

Best Wildflowers for Woodland Gardens

Wildflowers	Description	Conditions	Comments
American campanula (*Campanula americana*)	Spikes of azure blue open-faced stars appear summer through fall on a branching 3-5' plant.	Sun to full shade. Annual. Self-sows. Average, well-drained soil. All zones.	Unusual color for the shade. Scatter seed generously in fall; may not germinate until second spring. Let plants self-sow.
Bloodroot (*Sanguinaria canadensis*)	White stars and large, blue-green lobed leaves. Plants reach 8". Blooms in early spring.	Partial to full shade. Average, well-drained soil. Zones 3 to 9.	Reliable very early spring wildflower. Naturalizes well. Roots "bleed" red sap.
Dutchman's breeches (*Dicentra cucullaria*)	Mounds of lacy gray-green foliage and arching stems of little creamy "pantaloons." Appear in spring. Plants reach 8-12".	Partial to full shade. Humusy, well-drained soil. Zones 3 to 9.	Charming but tough. Spreads into colonies.
Fringecups (*Tellima grandiflora*)	Stems of tiny fringed green, white, or pink bells appear above rosettes of rounded, hairy leaves. Blooms in spring. Reaches 12".	Partial to full shade. Average, well-drained soil. Appreciates humus. Zones 4 to 9.	A northwestern native that combines beautifully with other shade perennials. Foliage persists after blooming, like heuchera, which it resembles. Spreads by thick rhizomes and will form a groundcover in loose, organic soil.
Jack-in-the-pulpit (*Arisaema triphyllum*)	Unusual peek-a-boo flower with hooded spadix over erect spathe, the "Jack." Plants have two three-lobed leaves. Blooms in spring. Reaches 2-3'.	Partial to full shade. Average, well-drained soil. Zones 4 to 9.	Tight clusters of bright red berries are relished by chipmunks and other wildlife.
Mayapple (*Podophyllum peltatum*)	12" high umbrella of usually one rounded, multipart leaf; some plants branch into two leaves, hiding a single waxy white flower at their juncture. Blooms in spring. Reaches 1-2'.	Sun to full shade. Average, well-drained soil. Zones 3 to 9.	Watching the furled umbrellas of mayapple push through the soil and then open over a few days is a simple pleasure. Rhizomes spread freely in loose, organic soil to form colonies.
Wild sweet William (*Phlox divaricata, P. stolonifera*)	Semi-evergreen creeping perennial with beautiful blue-lavender flowers produced in great abundance in spring. Reaches to about 12" when in bloom.	Sun to full shade. Average, well-drained soil. Zones 3 to 8.	A beautiful companion to spring bulbs. Both species spread into large, loose mats. Several cultivars in various colors are available, but the species are worthy as is.

Best Groundcovers for Woodland Gardens

Groundcovers	Description	Conditions	Comments
Canada mayflower (*Maianthemum canadense*)	Also known as false lily-of-the-valley, a more descriptive name, this 6" native bears a single stem with two or three leaves topped in spring to summer by a cluster of small white flowers.	Partial to full shade. Loose, humusy soil; also thrives in poor soils. Zones 2 to 9.	Spreads by slender, creeping roots. Slow to establish at first. Nice as a textural accent with other ground covers.
Foamflower (*Tiarella cordifolia*)	Clumps of 1" or taller foliage like heucheras, with feathery spikes of tiny, creamy white flowers rising above the leaves. Spreads rapidly by stolons. Blooms in spring.	Partial to full shade. Moist, humusy soil; does not tolerate drought. Zones 3 to 9.	Beautiful with wild phlox and other native wildflowers. Allow fallen leaves from overhead trees to remain in place as a mulch. Don't be fooled by the variety collina (*T. wherryi*), which looks just like the species but doesn't spread.
Green-and-gold (*Chrysogonum virginianum*)	Rosettes of triangular, dark green leaves topped with short-stemmed bouquets of bright gold daisy flowers; plants grow to 6-23" tall. Blooms in spring.	Partial to full shade. Average garden soil; very adaptable, but not drought-tolerant. Zones 5 to 9.	Nice as an underplanting to shrubs. Long period of bloom, with sporadic flowers through summer.
Waterleaves (*Hydrophyllum* spp.)	Beautiful silver-splashed leaves grow from knotty, fast-spreading rhizomes. White or blue spring or summer flowers have fuzzy stamens. Reaches 1-1½'.	Partial sun to full shade. Widely adaptable. Zones 3 to 9.	Large-leaved (*H. macrophylla*) and broad-leaved waterleaf (*H. canadense*), shorter species with wide, silver-spangled leaves, are my favorites.

Best Shrubs for Shade Gardens

Shrubs	Description	Conditions	Comments
Korean azalea (*Rhododendron mucronulatum*)	Deciduous shrub to 8' with rose-purple flowers in early spring.	Partial to moderate shade. Acid, organic, humus-rich soil. Zones 5 to 8.	Blooms extremely early. Beautiful with emerging ferns.
Rhododendrons, evergreen (*Rhododendron* spp.)	Many cultivars. Evergreen shrubs with large, oval, glossy leaves and big trusses of flowers, often fragrant. Reaches 6-12' or taller.	Sun to full shade. Zones 4 to 8.	The sheltering leaves of evergreen rhododendrons give structure to the winter garden and offer birds protection in inclement weather. Flowers are visited by hummingbirds.
Red-flowered currant (*Ribes sanguineum*)	Deciduous shrub to 12' with very graceful form and dangling clusters of unusually fragrant deep pink or red flowers in early spring.	Partial to full shade. Humus-rich, moist, acid soil. Zones 5 to 6 (7).	This pretty shrub offers very early spring bloom for hummingbirds and berries for other wildlife.
Witch hazels (*Hamamelis* spp. and hybrids)	Deciduous shrubs or small trees with odd flowers like scraps of bright ribbons in spring or fall. Some are winter blooming.	Partial to full shade. Average soil; vernal witch hazel (*H. vernalis*) and Virginia witch hazel (*H. virginiana*) also thrive in moist soil. Zones 5 to 8.	Carefree shrubs with flowers just when you need them most—the doldrums of late winter. Vernal witch hazel (*H. vernalis*), to 10', has attractive, vase-shaped habit and blooms in very early spring. Virginia witch hazel (*H. virginiana*) is larger and blooms in fall and winter. Chinese witch hazel (*H. mollis*) is a Chinese species with yellow flowers in late winter. Hybrid witch hazel (*H.* x *intermedia*) has several cultivars.
Hollies, evergreen (*Hex* spp. and hybrids)	Evergreen shrubs and small trees with prickly leaves and showy red berries. Reaches to 50'.	Partial sun to shade. Average, well-drained soil. Hardy to Zones 4 to 9, depending on species.	Good evergreens for winter interest and shelter. Abundant berries are favorites of robins and other birds.

The biggest problem with container water gardens is that they're too small. Water plants move faster than Napoleon, and their aim is the same—to expand their empire. Even if you choose well-mannered plants, you'll soon run out of room for more than a few. What to do with the rest? If you're still not ready to install a pool, try a metal horse trough. These are long and narrow, shaped like a throat lozenge with rounded corners, and they have plenty of room in which to create a good garden. You can buy them new at farm-supply stores, or check country auctions. I found an old one at a farm auction for a few dollars; I gave it a once-over with a can of black, matte-finish spray paint, and it did the job perfectly.

Natural Water-Garden Style

It's not difficult to put in a pond, but it takes some thinking to make it look natural. I love ponds and pools, but I wince at the unnatural stone edging I see all too often, even in the pages of the best water-garden-supply catalogs. Rubber and polyvinyl chloride (PVC) liners have made it easy for pools to hold water, but the trouble is that the ponds too often end up looking artificial. They're surrounded by an edging of flat stone, laid as carefully as a flagstone walk. No matter how many water lilies grace the surface, the hand of a human is all too apparent in these gardens. I prefer my water gardens a little wilder, so they look like something that might have been there forever, not like something that was built from a kit and a truckload of stone.

For a natural look, you'll want to start with an irregularly shaped pool. Leave the rectangles and circles to formal gardens; their lines are too rigid to blend into a natural landscape. If you should happen to have a pool with a regular outline, you can disguise it with plantings that spill over its edges and merge naturally into nearby gardens. Japanese maples, which dip their weeping branches down to the water's surface, can soften almost any pool.

Pool Options

In years gone by, if you wanted a water garden, you had to mix cement and mortar and tackle an enormous project that makes me tired just thinking about it. But water gardens are getting easier every year. With the advent of PVC and butyl rubber liner sheets, installing a pool is well within the reach of even mechanically challenged gardeners.

It's perfectly possible to install a backyard pool in one weekend of intensive labor, but I prefer to do it in three easy steps: I devote one weekend to planning and shopping, one to digging and installing, and one to planting and filling.

You'll save yourself some time and trouble if you call on your friends when it's time to put in the liner. They can help position the liner and hold the edges in place while you secure them. Liners are heavier than you'd think, and without several pairs of hands, it's easy for part of the liner you've just positioned to slip down into the hole. Also, it's a good idea to install the liner on a sunny day—let it warm up in the sun first, so it's flexible and easier to handle.

Remember that smoothing out a liner isn't as fussy as making a bed. Don't worry about pleats and wrinkles in the liner; they'll soon be hidden by algae and the slight natural cloudiness of the water.

Best Trees for Shade Gardens

Trees	Description	Conditions	Comments
Kousa dogwood (*Cornus kousa*)	Small tree with layered branches and white bract "flowers," similar to flowering dogwood. Blooms in spring. Reaches to 20'.	Sun to moderate shade. Moist, organic soil. Zones 5 to 8.	This appealing tree and the related hybrid Stellar dogwoods (*C.* x *rutgersensis*) are vigorous and trouble-free. The red fruits are supposedly attractive to birds, but go ignored on my tree.
Cornelian cherry (*Cornus mas*)	Small tree with shrubby, multitrunked habit and cheerful yellow bumbles of tiny flowers along the bare branches in early spring. Reaches to 20'.	Sun to moderate shade. Average, well-drained soil. Drought-tolerant. Zones 4 to 8.	A tough little tree, undemanding and adaptable. Looks great underplanted with Virginia bluebells and muscari. Red berries follow flowers and are eagerly sought by birds.
Japanese plume cedar (*Cryptomeria japonica* 'Elegans')	An elegant evergreen conifer with soft clouds of green foliage shading to red and blue. Reaches to 150', grows to about 50' in a garden setting.	Sun to partial or light shade. Average, well-drained soil. Zones 6 to 9.	Adaptable and trouble-free. Needles look sharp, but are soft and springy to the touch. Foliage becomes tinged with plum purple in cold weather.
Red buckeye (*Aesculus pavia*)	Small tree or large open shrub with candelabras of tubular red flowers in spring. Foliage resembles that of horsechestnut. Reaches to 12'.	Sun to full shade. Average, well-drained soil. Zones 6 to 9.	One of the first trees to unfold its foliage in spring. Flowers are much sought by hummingbirds.
Serviceberries (*Amelanchier* spp.)	Small trees or shrubs with delicate, white, cherrylike blossoms in spring and blue-black fruits that are tasty to man and beast. Reaches to 5-20'.	Sun to moderate shade. Well-drained, acid soil. Zones 4 to 9, depending on the species.	The native serviceberries are enjoying a new popularity among gardeners, so more cultivars are appearing in catalogs and garden centers.

Best Wildflowers for Shade Gardens

Wildflowers	Description	Conditions	Comments
Heucheras (*Heuchera* spp. and hybrids)	Rosettes of pretty scalloped leaves with graceful 12-18" stems of white, pink, or red flowers. Blooms in spring or summer.	Sun to partial or moderate shade. Average, well-drained soil. Zones 3 to 9, depending on the species.	Many newer hybrids have gorgeous foliage, 'Pewter Veil' has dark-veined silvery leaves.
Trout lilies (*Erythronium* spp.)	Mottled or clear green leaves arising from a deep-set bulb, bearing a pretty nodding, six-petaled flower in yellow, white, purple, or varied colors. 6-24" tall, depending on the species. Blooms in spring.	Light to full shade. Moist, humusy soil. Hardy to Zones 2 to 8, depending on species.	Trout lilies get their name from the leaves, which are often speckled with brown or purple like the belly of a trout. They are long-lived and multiply, but may be slow to bloom after planting.
Virginia bluebells (*Mertensia virginica*)	An ethereal early spring beauty with light green oval leaves and 1-2' stems of dangling bells of rain-washed blue. Buds are pink. Blooms in spring.	Partial shade. Moist, humusy soil, but will also grow in clay. Zones 3 to 9.	Dies back completely after blooming, so plant among groundcover that can later camouflage the bare spot, or overplant with other shade-loving annuals.
Wild bleeding heart (*Dicentra formosa, D. eximia*)	Lacy, gray-green foliage in shaggy 18" clumps with arching stems of pink hearts strung along a bare stem in spring.	Partial to full shade. Moist, humusy soil. Zones 2 to 9.	Wild bleeding heart (*D. eximia*), the native eastern species, does better in humid summer heat than the western species, Western bleeding heart (*D. formosa*), which is more drought-tolerant.
Wild columbine (*Aquilegia canadensis, A. chrysantha*)	Intriguing, long-spurred blossoms above rosettes of lacy, gray-green foliage. Yellow-flowered *A. chrysantha* grows to 3½'; red and yellow *A. canadensis*, usually about 2'.	Partial sun to full shade. Average, moist garden soil. Zones 3 to 9.	Favorites of hummingbirds. Long period of bloom.

Best Groundcovers for Shade Gardens

Groundcovers	Description	Conditions	Comments
European wild ginger (*Asarum europaeum*)	Glossy, leathery, heart-shaped leaves appear in spring and spread in mats about 6" high. Evergreen.	Light to full shade. Well-drained, moist soil. Zones 4 to 7.	The shiny leaves are eyecatching among other textures in the garden.
Lungwort or Bethlehem sage (*Pulmonaria saccharata*)	Pretty pointed oval leaves are generously splashed and dotted with silvery white, an effect that subtly adds light to the shade garden. The 12-18" tall plants gradually spread to about 2 feet.	Light to full shade. Well-drained moist soil. Zones 3 to 8.	The spring-blooming flowers are similar to Virginia bluebells: they open pink from pink buds, then age to light blue. Pink and white cultivars are also available. If your summers are hot and humid, try long-leafed lungwort (*P. longifolia*), with extremely long, slim leaves spotted silvery gray and clusters of purple-blue spring flowers.
Western beach strawberry (*Fragaria chiloensis*)	Mat-forming strawberry with very shiny, deep green leaves. White flowers and red berries shine among the foliage.	Sun to partial or light shade. Very adaptable. Does best in loose soils and thrives in sand. Hardy to at least Zones 3 to 9.	A beautiful, low-maintenance ornamental. Birds, turtles, and toads appreciate the fruits.
Wintergreen (*Gaultheria procumbens*)	Creeping, prostrate evergreen shrub with small, shiny leaves and scarlet fruits in summer and fall.	Partial to full shade. Moist, humusy, acid soil. Zones 4 to 7.	Does best in cool climates. An old favorite for glass-bowl gardens.
Yellow, corydalis (*Corydalis lutea*)	Lacy, pale blue-green foliage, 8-15" high, looks good all season. Dainty, spurred yellow blooms held on wiry stems. Most abundant in spring, the flowers show up sporadically until frost.	Light to full shade. Well-drained, moist soil. Zones 5 to 7.	Self-sows, with a charming habit of showing up in niches of rock walls or brick paths. A fine-textured companion for hostas. Tricky to start from seed; buy plants instead.

This water garden evoked memories of the old oaken bucket. A pair of variegated irises draws attention to the always-trickling pump.

Continued ➔

Water Garden Options

These days, when it's time to put in your pool, you have several choices of water garden or pond liners. Concrete is still an option, but there are better materials available, including plastic and rubber sheet liners, preformed plastic pools, and an old farm-pond standard, packed clay. Here are the pros and cons of each.

Type of Pool	Pros	Cons	Recommendations
Concrete	Long-lasting. Reasonable price.	Messy, hard work. May crack from thawing ice. Alkalinity from lime may affect water balance.	Not recommended.
Packed clay	Cheap. Good for large-size pond in area with naturally heavy soil or where water naturally accumulates.	Heavy labor. Requires pounding with a rammer or sledgehammer or by repeated rolling. Large equipment may have to be brought in, which can damage lawn and garden.	Not recommended except for very large ponds. If you have a naturally boggy site, it's easiest to plant a bog garden there and install a lined pool elsewhere.
Plastic or rubber sheet liners	Can follow any shape or contour. Less expensive than a preformed pool. Can be extended beyond pool to create bog garden. Allows quick growth of algae on bottom and sides to disguise artificial nature of pond lining. Forgiving of excavation irregularities because it drapes easily.	Must be carefully installed to avoid sharp objects and leaks. Edges must be held in place with rock, timbers, or brick. Be sure to buy a liner that resists damage from ultraviolet light (sunlight). Butyl rubber lasts up to 50 years; less-expensive PVC lasts for 5 to 15 years.	Best choice for pools and ponds. Also good for streams and waterfalls, and excellent when used in combination with preformed sections in waterfalls and streams.
Preformed	Easy to install. Small sections can be linked together to form streams or waterfalls. Rigid pools will last for up to 50 years. Often include built-in shelves for plants.	More expensive than other options. May not be size or shape desired. If you want a bog garden nearby, it will have to be created separately. Most are too small for an effective natural pond. Many are too shallow (less than 2 feet) to accommodate overwintering fish and plants. Can crack without proper soil support. Edge looks unnatural and must be disguised.	Small units are excellent for creating waterfalls and streams, either alone or combined with lined sections.

Edging Your Pool with Rocks

Liners and preformed pools are easy to install, but their plastic edges will stick out like a sore thumb unless you hide them. Rocks are the best choice for the job because soil alone will soon wash into the pool with the next good rain.

However, there's no law that says the rocks that hold the liner in place or disguise the edge of the pool must be all the same size. Incorporate several large rocks (or boulders if you can manage them) into the edging. Group them together naturally, varying the height by using rocks of different sizes or by layering them. Bury the bases of larger rocks partway into the soil to make them look natural. Extend the rocks into the surrounding garden, blending them in with grasses and shrubs.

Be sure to use rocks that occur naturally in your area. Chunks of lava, for example, will look out of place in a limestone region. Keep in mind that quarried stone will also look different from weathered rock. The retaining wall of bright white quarried limestone in my garden stuck out like a spotlight until time added lichens, mosses, and natural stains to its surface.

Mottled or medium- to dark-colored rocks will blend into surrounding vegetation more easily than light-colored limestone or sandstone. But beware of a higgledy-piggledy effect of mixed colors. For a natural look, choose your rocks so that the colors blend with each other.

Sandstone will absorb water, which makes it a great place for mosses to start colonizing. Algae will colonize the rock first, giving it a green patina that makes it look like it's been part of the garden for a long time. Then mosses and lichens will move in. The drawback with sandstone is that much of the water it absorbs is lost through evaporation, so you may have to refill the pool more often.

Granite and slate don't suck up water like porous sandstone, and they're less hospitable to tiny rock plants. Their surfaces remain mostly bare until they're colonized by lichens. Use these rocks as accents or anchors around your water garden. If the rocks you're using are already weathered, remember your nature lore when you situate them: Moss grows on the north side.

Consider the angles of the sides of the rocks when you position them. If your rocks slant in all different directions, your pool won't be a restful place. The clashing angles will jangle your view.

Try to include one or two substantial, flat-surface rocks near the pool as sitting spots. But keep them back from the lined edge to avoid collapsing the edge into the water when you sit on them!

Water Garden Visitors

Water gardens are rich with wildlife. Some will come to live there, some will come to drink, and others will come to dine. Here are some you might encounter.

Beavers, mink, otters: They may move to an isolated pond or stream, or you may see them eating or fishing.

Bitterns: You'll spot them looking for food or standing with beak stretched to the sky among the reeds. Watch for the least bittern, a tiny heron the size of a robin.

Cedar waxwings: They'll be flycatching—grabbing insects while in flight over the water.

Dragonflies and darners: Larvae are aquatic; adults are beauty on the wing in colors of silver, turquoise, cobalt, brilliant tropical green, and red.

Ducks: Only a big pond will draw ducks. If your pond is in the woods and away from human activity, you may be lucky enough to land a wood duck, the beauty queen of the duck world. Wood ducks are more reclusive than Howard Hughes. Unless you're very sneaky, you're more likely to see them fleeing than swimming.

Frogs: They'll move in fast and become summer-long residents.

Herons: You'll see them fishing for dinner.

Hummingbirds: Watch for hummers sipping from jewelweed near the water or collecting spider silk for nests.

Mayflies: Flat "bugs" with 3-pronged tails on submerged rocks are mayfly larvae. They hatch all at once, take to the air, and live only hours.

Minnows and other fish: Fish are brought in as eggs on bird feet.

Muskrats: They may be eating cattails or burrowing into walls.

Northern harriers (marsh hawks): These hawks will be patrolling for mice and rodents.

Nutria: Nutrias like to nibble on reeds and vegetation. They look like giant hamsters on steroids.

Opossums and skunks: These nocturnal critters will be scouting for food or looking for a drink.

Predaceous diving beetles: Big, black, and mean, those jaws mean business to unlucky aquatic insects or larvae.

Raccoons: You may see one washing up before dinner or catching frogs and fish.

Red-winged blackbirds, swamp sparrows, song sparrows: They may nest in reeds or other vegetation.

Robins and other songbirds: Look for these busy birds bathing and drinking, as well as nesting in nearby vegetation.

Spring peepers and chorus frogs: They'll call for mates in early spring, then disappear. These are tiny, thumbnail-size guys with a voice as big as Maria Callas's.

Tadpoles: Look for them on submerged decaying vegetation or on the bottom in the shallows.

Turtles: They'll be basking on logs or swimming. Look for black dots breaking the surface of a pond, and watch to see if they suddenly disappear or move: Those are turtle heads.

Voles: Voles may set up den tunnels in the banks.

Water striders: Watch them skate on the surface film. These are resident, spiderlike insects.

Whirligig beetles: You can see them whizzing in circles on the water surface, in tight groups of dozens or hundreds. They look like tiny silvery bumper cars at high speed.

Yellow warblers: Warblers may nest in willows and other shrubs near the water.

A cobblestone "beach" makes an appealing approach to a small section of your pond or stream. Place rounded river stones closely together, leading from shallow water to a grassy or boggy area near the water garden. (I always wondered where cobblestones got their name until I walked the Oregon beaches, where smooth, round stones of basalt cover the sand. As the waves washed in and then receded, the stones knuckled against each other with a wonderful, low-pitched "cobble-cobble-cobble" song.) Animals and birds are quick to take to a cobbled beach, where the stones give them a feeling of safety as they drink and bathe.

Plants are the best tool for softening the stony edges of a lined water garden. After you get your rocks in place, plant sprawlers, weepers, and creepers that will insinuate themselves over and between the rocks.

Planting a Pool

Planting a pool is not like planting a garden. Most water gardeners plant containerized plants rather than transplanting the roots into the soil, unless they have an unlined pond with a clay bottom. "Planting" is mostly a matter of moving pots

Continued ➔

Installing a Pool

Call on a friend or two to help make the work go faster and easier when you install a preformed pool. Many preformed pools come with a stepped edge, which allows you to grow plants that like shallow water near the edges.

Step 1: The old carpentry adage, "Measure twice, cut once," also holds true for digging. Hold the preformed pool right side up to mark its outline with stakes and rope or string.

Step 2: When the hole is dug, insert the pool and check for levelness and fit. Be sure the preformed ledge, if there is one, is well supported by soil beneath it.

Step 3: Laying in a liner is easier with a helper. Lap the edges into pleats to ensure a smooth fit, but don't worry too much about wrinkles, which will be invisible once the pool fills.

Step 4: Line the edge of the pool with rocks to hold the liner in place. Vary the size and shape of the stones, and pile some in groups to mimic Mother Nature's freeform arrangements.

Step 5: Plants are the finishing touch. Lilies and other water plants can spread surprisingly fast. Be sure to keep some water clear as your plants mature; the view of water is one of the pleasures of a pond.

5.

around. Some suppliers sell plants already in pots; others sell bareroot plants that you pot yourself.

For the most pleasing view of your water garden, keep at least half of the water free of plants. Otherwise, you may begin to feel like you're in some plant-choked inland canal.

Fill the pool to a depth of at least 1 foot, or below the level of your knees, before planting. Deeper water makes it harder for you to maneuver while planting. Plant from the center outward.

Start with aquatics, like water lilies and lotus, which do well in deep water. Aquatic plants are usually planted in containers with slatted sides that are open to the water. Because they are rampant growers, they'll need dividing when growth shows signs of becoming stunted. Tie a "handle" of plastic string across the top of the basket before you settle it into the pond. That makes it easy to lift later, to reposition or repot the plant. All you do is slip the handle of a hoe under the plastic handle and lift the pot out of the water.

Position young water lilies about 6 inches beneath the surface, by stacking shallow blocks or bricks beneath the pot, so that they don't exhaust themselves trying to reach the surface. As the plant gets stronger, you'll see more leaves appearing on the surface. That's when you can begin removing the blocks gradually, one at a time, until the pot is resting on the bottom of the pond.

After you place the aquatics, add a few oxygenating plants here and there; these fast growers will quickly fill in. Include two or three species of oxygenating plants, either planted separately or combined, but always in a container to control their rampant growth. Cover the soil surface of the pots with coarse gravel to prevent the soil from muddying the water when you submerge the containers.

Scatter a few floating plants, such as water lettuce, which dangle their roots into the water instead of getting nutrients from the soil. Place the floaters where they'll look pretty and have a bit of elbow room.

Moving outward toward the pool edges, add marginals like arrowhead and pickerelweed, which thrive in shallow water. Then finish your planting with moisture-loving bog plants such as irises and marsh marigold in the wet soil around the pond's edges. You may notice in some books and catalogs that there's not a clear distinction between many bog plants and marginals. Most of these plants will flourish happily in either shallow water or boggy soil conditions—and some will adapt to life in an average garden bed!

Examine all plants for duckweed before you put them in the water. This tiny aquatic plant has leaves barely 1/8 inch long, but it can cover a pond with a film of green in no time.

Unless you live in a cold-winter area, where they grow as annuals, do not plant water hyacinth, water lettuce, or other aquatics that have achieved noxious weed status. If you're not sure what's welcome and what's not, call your county extension office or the Nature Conservancy.

Adding Fish

Fish in a pond are fun to watch. I prefer minnows and other small, dull-colored species to the bright ornamental goldfish or koi that populate many pools, but that's a matter of personal taste. Some gardeners become avid collectors of koi, which can cost as much as a purebred dog (or a car!). To me, koi look as out of place in a natural garden as a plastic flamingo would look in a meadow. (Of course, if I lived in China, where golden carp do appear in wild waters, or in Florida, where live flamingos stalk the grassy flats, I'd have a different outlook.)

Pond fish are available at the same places where you buy plants and water-garden supplies, or you can buy goldfish at any pet store. They'll grow to amazing proportions once they're in a pond. Check a bait shop for live minnows and small fish.

Wait a couple of weeks after you fill your pool before you add fish to allow the plants time to get rooted. Fish may dislodge even established roots as they poke around looking for food. Your mosquito population will nosedive once you have fish; wigglers (mosquito larvae) are a prime fish food. Fish also eat algae, so they'll help keep your water looking clear. And goldfish love to eat duckweed.

Sometimes simple is best. This water-lily garden mirrors the shapes of the flat rocks that rim the pool, lending a sense of serenity to the garden. Plants in the stone crevices soften the effect without hiding the architecture of the rocks.

Plants to Soften a Pool's Edge

Try these plants to disguise the edge of your pool. Some, like ivy and ajuga, trail over the water's edge. Others, like the ferns, astilbes, and heavenly bamboo, add a feathery look to the water garden. All will make the transition from water to land look more natural.

Astilbes (*Astilbe* spp.): Stalwart perennials with divided foliage and plumy spires of flowers, either arching or erect, in shades of red, pink, pink-purple, and white. Zone 4.

Brooklime (*Veronica beccabunga*): Beautiful, true-blue flowering tender perennial. The fast-spreading 1-foot-tall plant has a sprawling habit and succulent stems. Zone 8.

Bugle (*Ajuga reptans*): Familiar mat-forming groundcover with ground-hugging leaves and spikes of blue (sometimes pink) flowers. Zone 3.

Buttercups (*Ranunculus* spp.): Many species of buttery-yellow-flowered perennials. Aggressively invasive, which may be a positive trait in your water garden edging. Most to Zone 3.

Forget-me-nots (*Myosotis* spp.): Perennial and annual delicate pale or true blue flowers on scrambling, low-growing plants. A beauty. Most to Zone 3, but self-sow abundantly and often bloom first year, so can be grown as annuals.

Heavenly bamboo (*Nandina domestica*): Shrub with airy, bamboo-like foliage. Many good cultivars, from dwarf groundcovers with flaming red foliage to 5 feet and taller. Zone 6 or 7.

Ivy (*Hedera helix*): Find interesting ivies in the houseplant section; small-leaved or lacy-looking types are pretty along water. Hardiness depends on cultivar; experiment.

Japanese maple (*Acer palmatum*): Shrubs or small trees with graceful shape and lacy leaves. Zone 5.

Kenilworth ivy (*Cymbalaria muralis*): Delicate perennial vine with scalloped leaves and tiny lilac-blue flowers. Great in crevices of rock. Zone 6.

Maidenhair ferns (*Adiantum* spp.): Fine-textured queen of ferns with beautiful fronds on wiry stems. Easier to grow than it looks. Hardiness depends on species.

Marsh marigold (*Caltha palustris*): Glossy round leaves with waxy yellow flowers are a cheerful sight in early spring. Spreads fast. Zone 3.

Meadowsweets (*Filipendula rubra, F. ulmaria*): Tall plants with compound leaves and airy clusters of pink flowers; almost shrublike in stature. Spread into large stands. Zone 3.

Ornamental grasses: Many species and cultivars, all with grace. Hardiness varies.

Sedges and rushes (*Juncus* spp.): Many species and cultivars. Choose the ones that appeal to you most. Hardiness varies.

Watercress (*Nasturtium officinale*): Deep green, shiny leaves with tiny white flowers. Leaves have excellent spicy taste before flowering. Zone 5.

Even if you don't introduce them, fish may show up in your pond. I used to puzzle over this mystery—were they falling from the sky?—but then I learned that they come in as eggs on the feet of ducks, herons, and other water-visiting birds.

Great blue herons, merganser ducks, green herons, and other fish-eaters will make short work of your finny friends once they discover your pond. You can prevent predation by stretching netting across the pool or by weaving monofilament fishing line across the water at intervals and among the edging plants. Water plants and rocks will provide some protection for fish, but catching these slippery creatures is a heron's job, and they are masters at waiting for the right moment. If a determined bird finds your pond, only mechanical means can save your finny friends.

If you've stocked your water with dime-store goldfish that you don't mind losing to birds, think of your water garden as a glorified bird feeder. (It's also a good way to avoid winter guilt when fish are trapped in ice.) It's a treat to watch herons and other birds fish. Great blues often flip their catch into the air, then swallow it head or tail first. Kingfishers take their prize to a nearby tree limb and bash it into submission by slapping it against the branch.

At Hawk Mountain, a Pennsylvania observation point on the migration route of hawks, I once saw an osprey come flapping along, its talons firmly gripping a nice, plump, bright orange and white koi. As the bird flew past the lookout, it delighted us watchers by casually reaching down and tearing off a bit of sushi on the wing.

Bringing Water to Life

A waterfall or stream can add a delightful element to your natural landscape. Water runs downhill, but that doesn't mean you need a steep hillside to create a waterfall or stream in your garden. A stretch of falling water needs only a very slight incline

Plants for Every Niche

Water lilies are the first plants that come to mind when we think of a water garden, but there are lots of other possibilities. In fact, there are plants that are ideally suited to every part of your water garden, from deep pools to shallow edges and boggy areas. For a large pond to look good, you'll need a mix of plants from all of the following niches. A small pool can get by with only aquatics and floating plants, if they're what you really like. A bog garden, of course, needs only bog plants.

- Aquatics must have their roots submerged, so they should be planted in water that's 1 to 3 feet deep. Don't go overboard with aquatics; their big leaves can hide too much of the water. Aquatics include the familiar water lilies and lotuses, plus other less well-known plants like golden club, water hawthorn, and water violet.
- Floaters are surface plants like water lettuce and duckweed, which float on top of the water. They reduce algae by blocking sunlight and competing for nutrients, but they can also conceal the water. Floaters can overwhelm a pond because they reproduce so quickly. An occasional raking to remove the extras will keep the water visible. To remove duckweed, stretch a piece of cheesecloth over the tines of your rake or use a net to gather it.
- Oxygenating plants are mostly submerged, though their tops may be visible. They grow incredibly fast and help keep the water clear because they compete with algae for nutrients. They also add oxygen to the water, which is something your fish will appreciate. These plants have exotic names like cabomba, anacharis, vallisneria, and myriophyllum. But they've become familiar to us because they're commonly sold in aquarium shops to oxygenate fish tanks. A newly planted pool will probably horrify you in a week or two, when the water turns green from algae. Be patient, though, and soon your oxygenating plants will starve out the scum.
- Marginals grow in the shallower water along the pond edge or in the very wet soil nearby. They're further divided into deep marginals, which like water about 12 inches deep, and shallow marginals, which grow well in shallow water (6 inches or less) or in wet soil. They include cattails, forget-me-nots, many sedges and rushes, and my personal favorite, western skunk cabbage.
- Bog plants are moisture-lovers that thrive in soggy soil. Once you see cardinal flower in full glory in a wet spot, you'll feel a little guilty about relegating it to a mixed border. Irises and sweet flag, royal fern, and astilbes also shine in boggy soil, along with a host of other interesting plants. Try button-bush, with its fuzzy globes of white flowers and persistent seedheads. Or start a collection of willows. I'm partial to pussy willows, but any of the family are glorious in winter and early spring, when their bare branches flush with color.

to be successful. Even in my flat midwestern garden, there are several good sites where water would naturally run downhill. If you can't tell the lay of your land by simply looking, lay out a garden hose, turn on the tap, and watch where the water goes.

A streambed or waterfall can be as long and elaborate or as short and simple as you have room and muscle to build. The basic idea boils down to this: You need an upper pool, or "top pool," where the water originates, and a lower pool, or "bottom pool," which contains the hidden recirculating pump that will return the water to the top pool.

I find that a simple design with a few broad shelves of rock where water can spill over is more restful than a tumbling, complicated streambed, but in this, as in all other garden matters, suit yourself. If you have a slope with a drop of several feet, a series of rock ledges will make a wonderful, natural-looking waterfall.

Both streams and waterfalls are easiest to make by using a flexible PVC or butyl rubber liner. The liner edges are easy to hide, and you can design the twists and turns in any way you like. Preformed sections can also be joined together to make a bed. Alter the angles between them to create meandering curves like those a real stream would carve out.

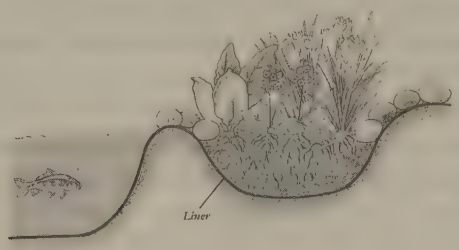
Because streams are free-form, with bends and variations in width from one pool to another, it's easiest to use separate pieces of liner for each section of stream, overlapping them at the ledges. A single liner is mighty unwieldy when you're working on a stream, but if you prefer to use one piece, round up a couple of patient friends to make the work go more smoothly.

Make your streambed wide—at least 2 feet—so that you can span it with a bridge and plants can spill over the edges without totally obscuring the watercourse. A stream can be much shallower than a pond because it won't be sheltering fish and

Continued ➔

Cross-Section of a Lined Pool

In nature, the plants you'll find at the edge of the water are bog plants that thrive in the wet or very moist soil naturally found there, But in a garden pond, the soil at water's edge is usually ordinary garden soil of average moisture, because the water is held strictly in place by the pond liner. To make bog plants happy there, you'll have to fool them by creating a mini-bog with an earthen dike and the pond liner.



Mound the soil at the edge of your pond as shown here to create a catch basin of sorts where bog plants will get the moisture they need. Rocks on the ridge help keep the liner in place.

Making a Streambed

Create the illusion of a natural stream by piecing together several preformed ponds or stream sections. Lay out the arrangement of the stream with a pair of garden hoses or with strips of cloth ripped from an old bedsheet. Start with a pool at the highest point. Move the outline around until you have a pleasing course. For a more graceful look, end the stream in a pool that is wider than the top pool.

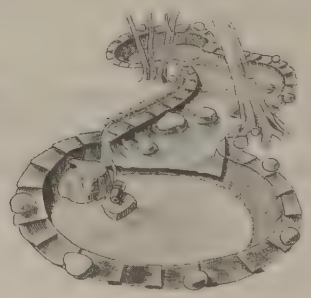
Plan your stream in sections. When you dig out the streambed, leave a ledge of soil between sections of the stream. That way, the water won't all drain down to the lowest pool when your pump isn't running.

Dig out a narrow trench a few inches from the streambed to carry the hose for the recirculating pump from the lowest pool back to the top pool. Remove any rocks or other sharp objects from the streambed and rake it smooth. Spread a layer of sand ½ inch deep over the bottom, or lay out a polyester padding liner in each section of stream. Lay the first piece of liner in the bottom pool, draping it over the sides and up the ledge to meet the second pool. Repeat as needed, overlapping the next liner on top of the previous one at the ledges between stream sections.

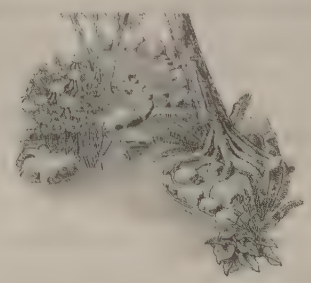
After installing the pump and pipe, lay stone around the edges of all sections to hold the liner in place and to cover the hose trench. Allow the liner to extend outward beyond the stones. For the most permanent results, set the stones into a mortar of fast-setting concrete, like Quikrete. Build waterfalls at the ledges if desired. (See "Building a Waterfall" on page 727.) Lay the liner in the small top pool. After you've put in the liner, lay stone around the outlet pipe of the recirculating pump, which will spill into the small top pool, to hide the pipe from view.

Scoop the reserved soil onto the exposed edges of the liner, filling in between the rocks at the sides of the stream and burying the bases or the rocks partway so they look well rooted in the ground. Walk on the soil to firm it down. Add plants to the banks of the stream, planting them into the soil beyond the liner. It won't take long before they creep to the water's edge, giving your creation the look of a natural stream. Be sure to set some water plants close to the edge so they can blend with the edging plants.

Dig out the stream, leaving a shallow ledge along the sides for anchoring the liner. Reserve the soil to cover the liner edges when your stream is complete.



Set the pump into the bottom pool on a flat stone base about 3 inches high. Site it close to the last ledge so that you don't have to run more pipe than necessary. Run the hose through the trench, along the stream, to the top pool. Fill in the trench with soil.



A leaky stream is aggravating, so check for leaks before you do the final touches. Fill the pools with water, and run the pump for about two hours to check for leaks. If water spills through the rocks and past the liner, mound soil under the liner at that point to raise it higher so that water can't escape.

water plants that need the protection of deep water from winter cold. Six to 12 inches is a decent depth for a stream.

A section of stream looks very odd if it ends abruptly. Disguise the terminus of your recycled stream by hiding it with shrubs or by extending the water garden into a bog. You can also stretch a streambed of dry rocks from the end of the water garden.

FALLING WATER FINESSE

Waterfalls have impact no matter what their size. Even the narrowest sliver of water can make a big splash, figuratively speaking.

Remember that all the water channeled into the fall will be pouring over the brink. To make a thin veil of water, you can widen a stream at the point of drop with a shelf of thin rock. If the edge is fairly even, the water will fall in a single sheet of silver. A jagged, irregular front edge of the rock will break the fall into sections. You can also train the water over the face of a boulder for a whole different look.

I've always liked the surprise of delicate ferns peeking out from behind a waterfall. You can allow for a little planting like this by building a pocket of soil into the ledge, behind the face of the jutting shelf of rock that creates the fall. You can also fake it by setting a potted fern behind the curtain of water, hiding its container with extra rocks.

You won't have to fake it for long, though. One of the most gratifying things about creating a water garden is seeing how plants find their own niches. Places where you'd never think

Calendar for Pond Care

Once your pond is planted, you'll want to watch for algae buildup, diseases or pests on pond plants, and leaks. If your winters turn cold and the water in your pond freezes, you'll have to make some allowances for tender plants and seasonal chores. If you garden in a warm-winter area, you'll need to control the growth of plants so that they don't overwhelm the water. Here are some season-by-season guidelines for good pond care.

Spring

Add marginal and aquatic plants. Rearrange plantings along the edge of the pool if needed. Clean out collected dead leaves and other debris from the bottom of the pool. Reconnect the submersible pump that was removed for winter storage. Bring aquatics out of winter storage and put them back into the pool. Collect rainwater in a wooden barrel for topping off the pool during the season; rainwater has fewer minerals than tap water, so it's less likely to cause algae growth. If snails begin devouring water-lily leaves, float some pieces of lettuce and skim them off with a net when they are full of snails. Listen for the chorus of courting frogs. Watch for migrating songbirds stopping by.

Summer

Refill the pond as water evaporates. Use collected rainwater, which won't change the chemistry in the pond. Rake or net off excess floating plants as needed to expose the water. Lift and repot any aquatic plants with stunted leaves or plants that produce lots of leaves but few flowers. Watch for green water, caused by excessive algae growth; add oxygenating plants to control. If long strands of algae form a blanket in the pond, rake them out and pile them on the compost heap. Protect fish from herons. Watch for leaks (dropping water level, wet soil) and repair with patches. Look for tadpoles and baby fish.

Fall

Put netting over the pool to block falling leaves. In cold-winter climates, remove the submersible pump. Remove yellowing foliage of water plants before it falls off into the water. Cut back oxygenating plants. Lift pots of tender water lilies and other tender plants before the weather turns cold. Overwinter tender floaters in a saucer of water in bright light, perhaps on a windowsill. For water lilies, slice off all growth to the crown and overwinter them in galvanized tubs in a cool garage. Or store the plants out of water for the winter by wrapping the pots in wet newspaper and storing in plastic bags in a cool but nonfreezing location. An old refrigerator, set to stay at about 35° to 38°F, is perfect.

Winter

Remove netting with fallen leaves. Adjust positions of rocks as needed. Check frequently to be sure water remains unfrozen if you have fish. Don't break the ice by hitting it; the shock waves can harm or kill fish. Install an electric pool heater if needed. Do not feed fish in winter in cold-winter areas; their metabolism slows as the temperature drops.

Continued

to plant are apt to be the spots where plants will pop up by themselves, their roots snaking into rock crevices to find the cool, moist soil below.

I love to watch mosses and lichens take hold on rocks by the water. Their textures and colors are beautiful, but in a subtle way that demands a close-up, unhurried look to appreciate the russets and olives, the incredible chartreuse and lime green.

Add a dead branch or log beside your streambed, and you'll be surprised how quickly it becomes softened by mosses. When mosses are silvered with fine spray, I can't resist running my fingers over them—but with only the lightest touch.

BRIDGING THE WATER

Bridges are more than a way to cross the water. They're a great place for dreaming and thinking, and they add physical beauty to the natural landscape. They also let you sneak up on things you otherwise couldn't get to, like that frog in the middle of the pond or the fish that hide out in deep water.

Keep your bridge as unobtrusive as you can. If a tree won't cooperate and fall in just the right place, you can use two unfinished wooden planks, at least 2 inches thick, to span the water. If the spread is wide, brace the boards partway across with a support of rocks. You can also build or buy a graceful bow bridge or a simple flat-plank crossing, with or without a rough handrail of saplings.

Build a Dry Stream

If you like the look of a flowing stream but don't want to pipe water into your garden, you can mimic a natural watercourse with a bed of stones. Look for a natural depression for your stream of stone. If the area is dry all year, start by laying down a blanket of thick black landscape plastic to block weeds. Then pour sand over the plastic and set in smooth, rounded river stones.

Some gardeners put a dry stream along a swale where water already drains. If the water comes fast and furious, the stones will be dislodged, so it's best to set at least a foundation course into mortar. Landscape the edges of your "stream" with clumps of ornamental grasses that imitate the look of reeds along a natural stream, but don't obscure the water. Keep it visible from a distance.

A dry stream may fool a casual human visitor, but wildlife won't be tricked into thinking it's water. Insects and spiders, however, will love your new landscape feature. Hunting spiders that spring upon their prey, rather than orb weavers, will move into the crevices among the stones.

Stepping stones can also get you out into and across the water. Settle them firmly so that a teetering stone doesn't surprise anyone into an unplanned dip.

The Bog Garden

I've always laughed when reading garden books that explained how to fix the drainage of a soggy spot. Shovel in sand and leaf mold, build raised beds, install drainage tile—why bother? That wet spot is a place to put in treasures that won't grow anywhere else.

My mother taught me how to turn problem sites into gorgeous gardens. When a place at the foot of a hill held water long after the rest of the yard dried out, she didn't frustrate herself by trying to grow bearded irises, dianthus, and daffodils that would have rotted in a single season. Instead, she brought in stately yellow flags (*Iris pseudacorus*) and partnered them with a clump of shorter sky blue irises (*Iris versicolor*) that swiftly grew into a wide-spreading mat. At their feet was a cloud of blue forget-me-nots (*Myosotis sylvestris*). My mother didn't know the lingo for landscaping, but her natural artist's eye told her what looked good together.

It was my mother who taught me to look at natural swampy spots and see what thrived and then to translate the best of those plants into a garden. I loved the wildness of cattails, but she knew they were rampant growers that would quickly swallow the rest of the planting. So she helped me plant their tubered roots in old galvanized buckets, where they'd stay put. Thirty years later, I'm still a cattail lover, but I've learned about other species more in keeping with the scale of my garden: a Japanese species (*Typha minima*) that grows cute, roundish balls instead of long, thick tails, and a native American species, *T. angustifolia*, which has long, slim cattails and narrow leaves that look as graceful as an ornamental grass.

If you like Japanese irises—those exquisite, veined blooms held wide open like angel wings, in soft purples, blues, and pinks—you'll love the way they flourish and spread in wet soil. They're one of the more expensive perennials, and I never had enough to satisfy me until I planted three of them at the end of our driveway, where water always puddled. I put in a weeping willow at the same time, with thirsty roots that helped soak up a lot of the standing water but left the ground moist. The irises outdid themselves in that problem spot, and for the first time in my garden, they began to multiply at a visible speed, almost as fast as daylilies.

Another plant that will adapt to ordinary soil but which shines in wet soil is the winterberry, or deciduous holly. The berries are fatter, shinier, and more plentiful on my bushes in a boggy spot than they are on the twin plants I placed in the "normal" garden. I planted them among a stand of soft rush (*Juncus effusus*) with deep black-green color that sets off the red berries. When the rush bleaches to tan in winter, it still provides good background texture and color for the dark-stemmed, red-berried holly bushes.

Building a Waterfall

A lovely, splashing waterfall can add more to your natural landscape than any other feature. And it's not much harder to build than a water garden. Once you've selected your spot, which should of course slope downhill, dig out a top and bottom pool, as described in the directions for making a streambed on page 724. Line the pool, then take a look at your rock collection to pick out suitable pieces for the waterfall.

Choose a relatively thin, flat rock that spans the stream to serve as the waterfall rock. A piece of slate or shale will work well, but pick one that isn't too flimsy-looking. Fill in around the main rock as described in the step-by-step directions below, then install a submersible pump in the base pool. Place it on a flat rock base about 2 to 4 inches high, close to the waterfall. Lay the outlet pipe into the trench along the pools, so that it exits at the upper pool. Fill in the trench.

Finish the edges of the pools with rock. Fill the pools with water, run the pump, and check for leaks. If you've built carefully, all you should hear is the refreshing gurgle of the water as it spills over your falls.

Step 1: After you have lined the top and bottom pools, drape another piece of liner over the face and ledge for the waterfall. This will protect the bottom liner from being cut by rocks.

Step 2: Settle the rock into position so that it juts out over the supporting face of the fall and anchor it between large supporting rocks at each side. Work mortar in between the waterfall rock and the liner so that water won't sneak through underneath it.

Step 3: Fill in behind and under the waterfall rock with smaller rocks, to create a seal that directs the water over the falls. Mortar these stones into place to prevent them from being dislodged by the force of the water.

Step 4: Fill in soil around the edges and between the rocks. Add plants. Then pat yourself on the back and bring your friends and family to the garden to see your new waterfall.

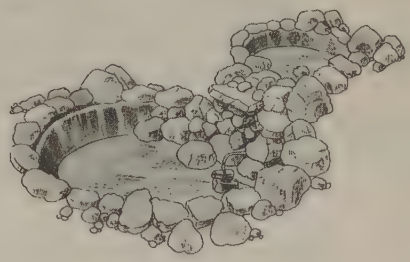
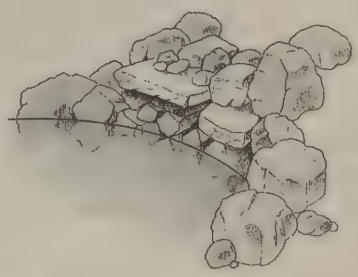
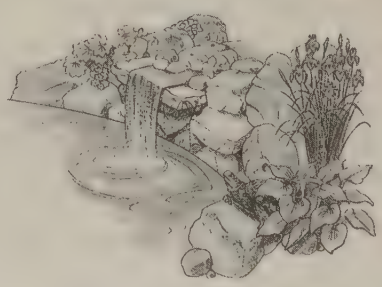
2.



3.



4.



MAKING A BOG

Ponds and streams in nature have wet, boggy edges, where water-loving plants thrive. Gardener-built water features, however, are a different story. If you use a liner or a preformed pool, the water is kept inside so that it doesn't seep out into the surrounding soil (unless you intentionally install it that way). The plants outside the pool itself will have their roots in normal, dry soil.

Many bog plants are adaptable and will flourish even without constant moisture. You can create the effect of a bog garden beside a pool by using plants such as Japanese irises, which grow well in average soil as well as in true bogs, or by using plants with lush foliage.

But if you want a real bog, you can have a great deal of fun playing in the muck. If you're also installing a lined pool, you can make room for bog plants by leaving a stepped ledge along the top of the pool, anchoring the liner on the ledge with rocks. Then extend the liner from the ledge, allowing for a pocket of soil before sloping it upward above the water level. Bog plants will flourish in the saturated soil in the lined pocket.

Best Poolside Plants for Water Gardens

These plants are appealing near water. They thrive in moist to wet soil.

Poolside Plants	Description	Conditions	Comments
Astilbes (*Astilbe* spp.)	Easy to grow perennial with feathery plumes, either upright or arching, in shades of pink, red, or white above ferny clumps of divided leaves.	Sun to shade. Moist soil. Zones 3 to 8, depending on species.	Most astilbes are hybrids (*A. x arendsii*); the cultivar selection is enormous, from diminutive 1"-tall 'Glow' to 'Purple Blaze,' which can reach almost 5'.
Feather reed grass (*Calamagrostis acutiflora*)	Upright, 1-2' tall arching grass with showy panicles of flowers held well above the foliage.	Sun. Moist soil. Zones 5 to 9.	The cultivar 'Stricta' is deservedly popular.
Forget-me-nots (*Myosotis* spp.)	Annual and short-lived perennial species of low-growing, mounding habit with myriads of delicate sky blue or true blue tiny flowers.	Sun to moderate shade. *M. scorpioides* and *M. sylvatica*, two of the best, are hardy to Zones 3 to 8, depending on the species.	Longest-lived in cooler climates, but self-sow abundantly to renew and expand the planting.
Horsetails (*Equisetum* spp.)	Cylindrical, jointed, leafless stems grow in spreading colonies.	Sun to light shade. Moist to wet soil. Will also grow in average garden soil. Zones 3 to 11, depending on species.	Scouring rush (*E. hyemale*) is a common, widely adaptable species. The stems are banded with ash-color stripes.
Monkeyflowers (*Mimulus* spp.)	Several species of perennials with tubular flowers in various colors, including clear red, yellow, and blue.	Sun to part shade. Moist soil. Hardiness depends on species. Blue-lavender *M. ringens*, to Zone 3; red *M. cardinalis*, to Zone 7; yellow, often red-speckled *M. guttatus*, Zone 6.	An underused perennial with pretty and abundant bloom that lasts for a long time. Many self-sow, but never to the point of pestiness.

Water Garden Design

A natural pond, like almost every planting in nature, is incredibly diverse. Once you start to count the types of plants that grow in, on, and around the water, you'll find you get into double digits fast. While there's something to be said for the serenity of a water garden that holds just a few kinds of plants, I like to mimic nature with a grand jumble.

Shrubs and trees anchor this four-season planting. Bushes and irises add vertical exclamation points that play against the horizontal water. Of course the garden is filled with flowers, too, from the earliest pussywillows to the glorious lotuses of high summer and the unusually shaped turtlehead that closes out the season. In fall, baldcypress adds soft russet color, and grasses hold the spotlight into winter.

Plant List

Fill in nooks and crannies between perimeter stones around a liner pond and between larger plants with spreading or creeping plants that appreciate moisture such as:

- Marsh marigolds (white and yellow) (*Caltha palustris*)
- Primroses (*Primula* spp.)
- Forget-me-nots (*Myosotis* spp.)
- Moneyworts (*Lysimachia nummularia*)
- Manna grass (*Glyceria maxima*)
- Horsetails (*Equisetum* spp.), including contorted horsetails (*E. scorpioides var. contorta*)
- Youth-and-old-age (*Tolmiea menziesii*)
- Sweet white violets (*Viola blanda*)
- Monkey flowers (*Mimulus luteus* and other spp.)
- Dwarf sedges (*Carex* spp.)
- Buttercups (*Ranunculus acris*, *R. repens*, and other spp.)
- *Iris pallida* and other small irises

Use small water plants to add textural contrast on water surface:

- Water lettuce (*Pistia stratiotes*)
- Water clovers (*Marsilea quadrifolia*)
- Parrot feather (*Myriophyllum aquaticum*)
- Water buttercups (*Ranunculus flabellaris*)
- 'Pygmaea Alba' dwarf water lilies (*Nymphaea* 'Pygmaea Alba')
- Fairy moss (*Azolla caroliniana*)

Note: Integrate the pond/bog garden with other plantings; don't isolate it in the middle of a lawn. Plant outward from at least one side of the bog garden, using other plants as the soil becomes less moist.

Water and Bog Garden

1. 'Flamingo' Japanese silver grass (*Miscanthus sinensis* 'Flamingo')
2. Umbrella plant (*Peltiphyllum peltatum*)

3. Tall moor grass (*Molinia caerulea* ssp. *arundinacea*)
4. 'Flame' red willow (*Salix alba* 'Flame')
5. Rocks
6. 'Zebrinus' banded bulrush (*Schoenoplectus tabernaemontani* 'Zebrinus')
7. Sweet flag (*Acorus calamus*)
8. Goatsbeard (*Aruncus dioicus*)
9. Japanese irises (*Iris ensata*)
10. Cardinal flowers (*Lobelia cardinalis*)
11. Feather reed grass (*Calamagrostis acutiflora*)
12. Joe-Pye weed (*Eupatorium fistulosum*)
13. Pink turtlehead (*Chelone lyonii*)
14. Cotton grass (*Eriophorum latifolium*)
15. Royal ferns (*Osmunda regalis*)
16. Blue pickerel weed (*Pontederia cordata*)
17. American lotus (*Nelumbo lutea*)
18. Papyrus (*Cyperus papyrus*)
19. Water lilies (*Nymphaea* spp.)
20. Large decaying stump
21. Yellow skunk cabbages (*Lysichiton americanus*)
22. 'Bowles Golden' sedge (*Carex data* 'Bowles Golden')
23. Golden club (*Orontium aquaticum*)
24. Yellow flag (*Iris pseudacorus*)
25. Scarlet rose mallow (*Hibiscus coccineus*)
26. Hooker's pussywillow (*Salix hookeriana*)
27. New Zealand hair sedge (*Carex comans*)
28. 'Kleine Fontains' Japanese silver grass (*Miscanthus sinensis* 'Kleine Fontains')
29. Soft rush (*Juncus effusus*)
30. Baldcypress (*Taxodium distichum*)

Best Marginal Plants for Water Gardens

These plants are called "marginal" because you grow them in wet soil at the water's edge or in shallow water.

Marginal Plants	Description	Conditions	Comments
Arrowheads (*Sagittaria* spp.)	Glossy, arrow-shaped leaves in dense stands with spikes of white flowers accented with a purple blotch.	Sun to light shade. Zones 4 to 11, depending on the species.	Tubers of *S. latifolia* were once used as food by Native Americans.
Banded bulrush (*Schoenoplectus tabernaemontani* 'Zebrinus')	Upright, cylindrical green stems striped with horizontal yellow bands.	Sun to partial light shade. Zone 7.	This spreading rush makes striking colonies at a pond's edge and in shallow water.
Cattails (*Typha* spp.)	Strappy, erect leaves with stiff pokers of packed brown flowers, like cigars atop bare stems.	Sun. Wet soil and shallow water. Zones 2 to 11, depending on species.	Cattails are a fast-growing plant for the waterside, but they can take over small spaces in a hurry. Dwarf *T. minima*, a Japanese species hardy to Zone 4, has short, fat, brown spikes instead of long "tails," and is much less invasive.
Papyruses (*Cyperus* spp.)	Umbrellas or pompons of leafy green atop tall stems.	Sun to partial shade. Wet soil or shallow water. Zones 9 to 11.	Grow as pot plant and bring indoors for winter in cold climates.
Soft rush (*Juncus effusus*) and other rushes (*Juncus* spp.)	Upright or arching, grasslike clumps with tufts of soft brown flowers.	Wet soil or shallow water. Zones 4 to 9, depending on species.	Soft rush is a widely adaptable beauty with dark green foliage and showy flowers. Hardy to Zone 4, it turns brown in cold weather.
Sweet flags (*Acorus gramineus*)	Fans of irislike leaves that rarely bloom.	Sun to light shade. Moist soil or shallow water. Zones 4 to 11, depending on the species.	Foliage has a lovely, sweet fragrance when bruised. Once used medicinally.

Best Plants for Water Gardens

Aquatic Plants

These aquatic plants are for the deep-water part of your pond.

Plants	Description
Golden club (*Orontium aquaticum*)	Broad, strappy, velvety leaves with a showy stalk of golden flowers, 3-5' tall. Can also be grown as a marginal plant. Zones 6 to 11.
Lotus (*Nelumbo* spp.)	Many cultivars and species with wide, round leaves held above the water's surface. Showy, water-lilylike flowers, often fragrant. Tropical species survive only in mild-winter areas. Cold-hardy species including the American lotus (*Nelumbo lutea*) grow as far north as Zone 2 or 3. Most species are hardy in Zones 4 to 11.
Water buttercup (*Ranunculus aquatilis*)	Forms large spreading mats of small, three-lobed, floating leaves (and ferny submerged leaves) dotted with small, white, yellow-centered flowers that look like buttercups. *R. flabellaris* is similar, with yellow flowers. Zones 6.
Water lilies (*Nymphaea* spp.)	Many cultivars and species with wide, flat leaves that float on the water's surface. Beautiful flowers, usually fragrant. Some night-blooming. Most are tropical species that must be taken inside in cold-winter areas. Hardy types vary in their tolerance for cold; refer to nursery catalogs to find out which will grow in your zone. Zones 3 to 11, depending on species and cultivar.

Oxygenator Plants

These plants float or grow in the water. All spread rapidly and may need occasional thinning. A rake does the trick.

Plants	Description
Hair grass (*Eleocharis acicularis*)	Very skinny leaves like fine blades of wiry grass. Actually a water rush in the Cypress family. Grows in small tufts. Zone 4.
Milfoils (*Myriophyllum* spp.) including parrot feather (*M. aquaticum*)	Several species of beautiful feathery-foliaged plants that add soft, lush texture. Hardiness varies with species; beautiful light green parrot feather, to Zones 7; others grow in Zones 3 to 11, depending on the species.
Pondweeds (*Elodea* spp.)	Familiar aquarium plant with curled whorls of small, narrow-pointed leaves. Hardiness depends on species; common *E. canadensis* and *E. nuttallii* hardy to at least Zones 5 to 11, depending on the species.
Starworts (*Callitriche* spp.)	A dense mass of small plants with fine, whorled leaves and clusters of tiny, white star flowers. Sometimes called water chickweed, which it resembles. Several similar species. Hardiness depends on species; generally to Zone 5.

Floater Plants

These plants aren't rooted in the ground. They float in the water, usually forming mats.

Plants	Description
Frogbit (*Hydrocharis morsus ranae*)	Looks like small white water lilies, with leaves only one inch across. Many similar species, generally hardy to Zones 5 to 9.
Water chestnut (*Trapa natans*)	Interesting rosettes of diamond-shaped leaves with serrated edges on reddish stalks. White flowers followed by 1- 1¼" hard, black fruits that can be eaten. Naturalized in America as far north as New York. Zone 5.
Water hyacinth (*Eichhornia crassipes*)	An unwelcome pest in warm areas, where you should avoid planting it. In cold-winter areas, makes an attractive accent with bulbous-stemmed glossy leaves and pretty clusters of lavender flowers. Fish appreciate the cover formed by the abundant roots and runners. Only for cold-winter areas, where it will die after frost. Zones 8 to 11.
Water lettuce (*Pistia stratiotes*)	Another nuisance plant in warm areas, this pretty floater produces rosettes of pale green, wedge-shaped leaves like a tight-packed crop of garden lettuces. Do not plant in mild climates; in cold-winter areas, it will die with hard frost. Zones 8 to 11.

You can create a bog garden without a pond by installing a liner at a depth of about a foot. Punch holes into the liner every 3 feet or so to provide slow drainage. A child's rigid swimming pool makes a good underpinning for a small bog garden. As with the liner, open some holes in the bottom so that you don't end up with a mud puddle. I've always loved royal ferns. but my site wasn't right for these native American bog plants. Until, that is, I dug a hole and "planted" a $10 kid's plastic swimming pool. Then I filled it with leaf mold, sand, and compost, soaked it until it was as sopping as a wet sponge, and grew fantastic ferns.

Whether it's a ferny bog garden, a stream and waterfall, a lush pond, or a simple container water garden, nothing lights up a natural landscape like water. Try it and see. And water gardening is addictive—you may not be able to stop with just one garden. That's because water—and water plants—are so delightful. Your local birds, butterflies, and other wildlife will agree.

Sally Roth

The human touches you add to your natural landscape do as much to set the mood as the plants you choose to fill your gardens. Man-made elements like fences, walls, and path materials are major attention-grabbers in a garden. If they blend in gracefully, looking like something that might have occurred naturally, they'll reinforce the relaxed attitude of the garden. But if they clash with the style of the plantings, your garden will never look right, no matter how you shift the plants around.

Natural Fence Options

When I needed to fence part of my woodland garden to keep my dogs from wandering onto the road, I started by picturing the scene in my mind. I take a seasonal approach when I do these visualizations, imagining the garden with spring wildflowers, then cloaked in summer greenery, then mellow with autumn color, and finally in the bareness of winter.

I started my imaginings with a picket fence. How would a white picket fence look around my woodland garden? Way out of place, was the instant answer: Not only would the white paint draw attention like a beacon, but it would also emphasize the rigidity of regularly spaced pickets.

But I like picket fences, so I wasn't ready to give up on the idea altogether. In my mind, I gave the fence a coat of green-gray paint—now there's a job that's much speedier in the mind's eye than it is even for Tom Sawyer!—and tried the picture again. Spring and summer were fine because the fence was hardly visible. Fall wasn't bad. But in winter, the color looked artificial.

Back to the mental paint bucket. This time I went with a deep black-green, and I modified it further by making the pickets narrower and a little more rustic in design. In my mind, I planted shrubs against the fence here and there on both sides to create pockets of vegetation that occasionally obscured the wood. It was better, but still off.

Then I had a flash of insight: How about a weathered, unpainted fence? I kept the pickets narrow, stretched the fence a little taller, and tried it out. Perfect.

Of course, your choice of fence style is also mightily influenced by the thickness of your billfold. Luckily, compromise works well with fencing. You can use your desired, more expensive materials in short stretches, where they're most

Best Flowers for Bog Gardens

Flowers	Description	Conditions	Comments
Cardinal flower (*Lobelia cardinalis*)	Stunning spikes of vivid red flowers rise to 4' above a basal clump of foliage. Blooms in summer.	Sun to partial or light shade. Wet soil, but also grows well in average garden soil. Zones 2 to 9.	A hummingbird magnet. May self-sow with restraint, but more plants are always welcome.
Great blue lobelia (*Lobelia siphilitica*)	Bushy clumps of foliage topped by branching spikes of blue to blue-purple tubular flowers in summer. Reaches 2-3'.	Sun to partial shade. Wet soil or average garden conditions. Grows well in heavy clay. Zones 4 to 9.	Beautiful blue color and a long period of bloom. Cut back spent flower spikes to promote branching and rebloom until frost.
Japanese iris (*Iris ensata*, Higo strain)	The royalty of the iris clan, with 2-4" tall plants and stalks of two to four glorious, flat flowers in summer. Blue, purple, white, or reddish violet.	Sun to partial shade. Wet, rich soil. Also grows well in shallow water or in moist garden soil. Zones 8 to 9.	For best effect, plant several of a single cultivar instead of a hodge-podge. Magnificent flowers.
Marsh marigold (*Caltha palustris*)	Low-growing, mat-forming plants with glossy, round leaves and gleaming, butter-yellow flowers.	Partial sun to full shade. Wet or boggy soil. Also does well in moist garden soil. Zones 3 to 10.	Fast spreading, good for disguising the edges of artificial ponds. 'Alba' has white flowers.
Western skunk cabbage (*Lysichiton americanus*)	An arum with clumps of huge oval, pointed leaves and unusual callalike waxen yellow flowers with heavy, sweet-musky scent. Blooms in spring and summer. Reaches 1-2'.	Sun to shade. Wet soil. Zones 3 to 9.	Another native beauty saddled with an unfortunate name. Treasured in British gardens. Naturalizes well.
Yellow flag (*Iris pseudacorus*)	Statuesque 5' clumps of scrappy irislike foliage with fleur-de-lis-shaped yellow flowers in summer.	Sun to light shade. Moist soil to shallow water. Zones 5 to 9.	A beautiful plant for poolside. Spreads into a significant clump and may self-sow.

Best Ferns for Bog Gardens

Ferns	Description	Conditions	Comments
Cinnamon fern (*Osmunda cinnamomea*)	Robust clumps of erect fronds reach as tall as 5', and sprout clusters of cinnamon-color fertile fronds in the center of the clump.	Partial sun to shade. Widely adaptable. Thrives in wet, lime-free soil but also grows well in average, humusy soil. Zones 2 to 10.	Easy to grow and statuesque. Beautiful golden color in fall.
Maidenhair ferns (*Adiantum* spp.)	Many species of delicate-looking ferns with lacy texture, from 8-30" tall depending on species.	Partial sun to full shade. Very adaptable. Need moisture but also do best with good drainage; give them a spot on the rocks in a bog garden or create a pocket of soil among the poolside rocks. Hardy to Zones 2 to 8, depending on species.	Maidenhair ferns look beautiful near water and are worth the bit of extra trouble it takes to elevate their roots out of the wet soil. They naturally grow in woods, ravines, on waterfalls and cliffs, and at streamsides. Most have creeping roots that expand to form colonies. Although maidenhair ferns look incredibly delicate, they are tough and adaptable.
Royal fern (*Osmunda regalis*)	Airy but good-sized, forming clumps as tall as 10'.	Partial sun to light shade. Wet soil. Zones 2 to 10.	Easy to grow in the right place, and a beauty. Stays in a compact clump.
Silvery glade fern (*Athyrium thelypteroides*)	Creeping fern with erect, arching fronds to 4' tall. Silvery undersides.	Partial sun to shade. Damp, rich soil. Zones 4 to 9.	Easy to grow. The silvery color of the frond's undersides comes from the whitish immature spore-bearing sori, which are attached in rows beneath each leaf.

visible, and finish the job with inexpensive rolls of wire fence. Fast-growing shrubs and vines make good camouflage for the utilitarian parts of your fence. New plastic net fencing on the market, such as that sold for deer-proofing or construction, also makes a serviceable choice for fence-builders on a budget.

MAKE A TWIG FENCE

"Twig" fences are made of saplings or branches, not twigs. The name describes the style, not the materials. These fences have a rough, rustic charm that looks great in a natural landscape, and they're a good family project. Even a small section of twig fence lends immense appeal to the garden. You might use it to define the back border of your bird feeding area or to back up a bench.

To make one, you'll need a supply of branches that are about 1 to 2 inches thick and as tall as you want your fence to be. You'll also need some thicker wood, about 3 to 4 inches thick, for the horizontals and the section posts. If you don't have your own tree clippings, watch for work crews clearing utility right-of-ways or call a tree service.

Gather your branches while they're still green, and trim them to size with a hatchet. Strip off most of the smaller twigs, but leave some on to give your fence more personality. A simple picket-style fence is easy to construct. Nail the uprights to the horizontals at whatever spacing suits your fancy. Try to keep the spacing even, but don't be too rigid about it: Part of the charm of this kind of fence is its homemade imperfection. You can also lash the uprights together, using plastic twine for durability, followed by a wrapping of raffia for artsiness. If you want to experiment with a more complicated design, sketch it out on paper first. I've seen these fences done in rectangular sections, like a simple frame, with a crossed X of two pieces in each box.

LIVING FENCES

If you're not trying to keep animals in or out, a hedgerow makes a good fence. If you want to discourage traffic from canines and others, you can plant prickly pyracantha or barberries to discourage passing through. You can also hide a simple wire fence in the bushes if needed to keep critters where they belong.

Choose plants that provide food and cover for wildlife when you plant your hedge. Viburnums, roses, brambles, and other fruiting plants are ideal candidates.

Slope Solutions

I don't know about you, but I don't have very much mountain-goat blood in me. I'd much rather amble along level paths on a hillside than try to keep my footing on a slope. Terracing is a sensible solution that will let you get more out of your slope—not only will you be able to enjoy the garden more comfortably but you can also get a better view of it. And most important, a terraced hillside is less prone to erosion, as ancient farmers discovered millennia ago.

Making terraces is a matter of digging out soil from part of the hill and spreading it into a lower "raised bed," which you'll build out of wood or stone. I use landscape timbers, which are widely available, reasonably priced, and fairly easy to move around. Railroad ties are great, but they weigh a ton and are usually coated in creosote, which will make your whole garden smell like tar on hot days. (In addition, there is the possibility that toxins from the wood could leach into the soil.)

Like the rest of my gardens, my terraces were built in a free-form way. I didn't measure or calculate feet and inches; I worked by eyeballing as I went. My technique went like this: "Hmmm, let's put a path along here, now another step of the terrace, a little higher, a little higher there, perfect." If this method fills you with dread, follow the formula below.

Designing Paths

I depend on my dogs, my kids, and my own feet to show me where the paths should go. If the backyard traffic takes a shortcut through a flower bed, they're trying to tell me something. Unauthorized shortcuts are a clear message that the established path misses the mark. Unless they're in the mood for aimless

Simple lines and weathered wood look best in a natural garden. They set off the plants without calling undue attention to the manufactured elements in the garden.

Continued ➔

Natural Touches

It's always easier to play "what's wrong with this picture" than it is to decide what's right. The right garden bench can make a garden look great; the wrong furniture will stick out like a sore thumb and call attention to itself rather than to your garden. Here are some tips on choosing accessories that will match the mood of your natural garden rather than competing with it.

- Solid wood fences that create a wall seem to fade into the background.
- Fences with pickets or uprights are attention-getters. Their spaced lines create a rhythmic pattern that draws the eye. If you can't live without a picket fence, keep the pickets taller and slimmer than usual and more closely spaced.
- Think rustic when you're choosing a fence. Roughly split rails and posts that lean a little out of kilter are better than smooth, round, sanded rails and perfectly upright posts.
- Any painted objects in the garden will shout to be noticed, unless you choose a color that blends into the greenery. Muted, grayed midrange greens, black-green, and tans or browns are possibilities.
- Unpainted, weathered wood is least distracting.
- A patina of moss or lichens helps stone and concrete hardscape become a part of the garden. Instead of faking it with spray-on recipes, let the natural process of weathering be an education in another kind of plant succession.

wandering, animals and humans want a path that's the quickest route from one place to another. If you try to force their feet onto a winding, curving detour that wastes steps, they'll outvote you and create their own switchbacks.

When I'm planning a new garden, or a new path through an old garden, I follow different guidelines for different paths. If the path is from the house to the mailbox, from the house to the driveway, or leading to any other clear destination, I plan it as a utilitarian path—an express route. If it's a path for pleasure, then I let it meander. Of course, if human or animal footprints show me that a shortcut is needed, I make sure to include a straightforward route at that point, while still giving garden visitors the alternative of a slower, less direct trail.

Utilitarian Routes

When you want to keep your paths on the straight and narrow, use these tips. They guarantee that your family and friends will stay on the path and out of your gardens.

- Keep them straight, avoiding curves if possible.
- Make the path at least 3 feet wide for easy travel when carrying packages.
- Keep the surface level and "fast," as they say at the racecourse: Don't use loose gravel that will be hard to tread; instead, use packed material that will spur your steps. Wood chips will soon pack into a dense layer that makes solid footing.
- Be sure the path is easy to see, both during the day and at night.

GARDEN PATHS

When it's not necessary to get quickly from point A to point B, plan your paths so that you get the most you can out of your garden. You can weave your paths in curves and cross them back and forth over each other to make the stroll a longer one.

Learning from Nature

To make the man-made features in your garden look like a natural part of the landscape, use nature as your inspiration.

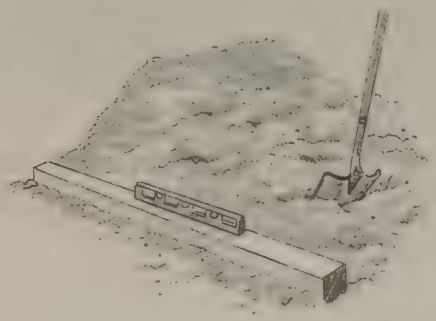
Garden Feature	Nature	Options
Accent rocks	Stone outcropping	Groups of lichened boulders set partway into the soil—not perched on top—so they look like they've been there forever
Fences	Weathered remnants of old homestead or farm fencing	Fences of simple design: split rail (not round rail); tall, narrow pickets; snow fence; twig fence. Fences of natural colors—unpainted, quiet greens, gray-greens, tans, or browns
Path	Deer trail	Wood-chip in woodland; footpath in meadow; grass or clover path. Gravel path in regions with naturally gravelly soil
Stepping stones through water or mud	Serendipitous stones or legs	Strategically placed stones or log rounds
Sitting spot	Natural objects	Flat-topped stumps; sizable, steady rocks; log bench; plank bench; unobtrusive natural wood bench
Wall	Evergreens or other natural vegetation	Wood walls planted with camouflaging vines, evergreens, and shrubs

Build a Terrace

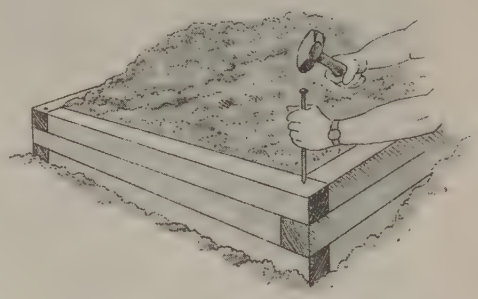
Before you begin digging, mark the outline of your terrace with string and stakes. Cut timbers for the sides of the beds to the length you've determined is your desired depth for each bed. Lay the first timber as shown below, then dig out the sides of the first bed, level with the bottom of the front trench and as deep as you have planned the bed. Lay in the first side timber. Repeat for the other side. Lay another front, overlapping it onto a side, then lay the sides and spike in place. Dig the soil out from the hill above to fill the bed you just made, and level it smooth. Add a back timber above the last course of sides, to form the front base of the second bed.

If this sounds like more work than you want to tackle, you might try a more informal approach. I've had good luck adding simple terraces, like a series of very broad, shallow steps, up a slope, using just a front timber or two for each step, and letting the sides of the bed roll into the natural hill. I hold the timbers in place by pounding in two stakes outside the wall. I fill in the slopes on either side of my "steps" with daylilies, butterfly bushes, and perennial hibiscus, and use the terraced steps for shorter, trailing plants, leaving a clear pathway to walk up and down.

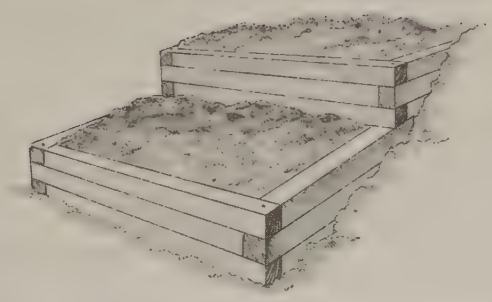
You can also use flat, fairly thin rocks or slate or even broken pieces of paving concrete as a retaining wall for terraces. Dig a thin trench about 3 to 6 inches deep and set the stones in vertically, leaning backward, with their faces turned outward. You might think this would look artificial, but if you plant alyssum, creeping veronica, and other sprawlers to spill over the edges of the slabs, it looks almost as good as a stone wall.



Dig a shallow trench to lay the timbers for the front of the first (the lowest) bed. It only needs to be a couple of inches deep. Settle the first timber into the trench.



Lay the timbers so that their ends overlap. Spike the front and sides in place with 10-inch galvanized nails, then lay the back timber of the bed, which actually forms the bottom timber of the front of the next bed.



Continue building and filling your course of beds up the hill, measuring to make sure the depth and height are going according to plan. Dig into the hill as needed to set the sides of each bed.

Plant in the beds and along the sides, to disguise the timbers and create the illusion of a hillside of flowers. Add some low-growing plants along the front, to spill over the edge.

Installing Low-Level Walkway Lights

A series of restrained, low-level pathway lights will make your steps surefooted after dark and show off your plants, too. Strands of electric path lights are available at any discount store. They're easy for even a novice to install, but you'll need an outdoor electric outlet within easy reach for plugging them in.

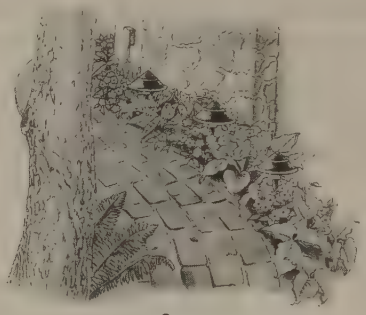
Step 1: Dig a shallow trench along the path where you want to install the lights.

Step 2: Measure the distance to the outlet, then lay in the cord and insert the lights at appropriate spacings. Cover the trench with soil and walk on it to firm it.

Step 3: Add plants around lights, being very careful not to dig into the trench where the wire is laid. Be sure the lights are unplugged until the planting is finished, so that you don't get a jolting surprise.

1.

2.



3.

Garden Paths Design

Multiply the pleasure of your garden by letting paths meander wherever there's room. Include a few intersections so that garden visitors can have choices of where to go next. Use shrubs to create a sense of mystery and anticipation of what's around the next bend.

You can adapt the ideas in this design to fit your own yard and your own plants. Work the paths around the existing trees and shrubs that anchor your garden. You can start with a basic framework of paths to get you to the mailbox, house, and car, and then add others as the garden evolves. I find that paths often suggest themselves—if I keep stepping into the groundcover to get a closer look at the caterpillars on the spicebushes, I add some stepping stones up to and around the shrubs so that I have easy access.

Path Design Key

Landscape Elements

1. Driveway
2. Front door
3. Utility meter
4. Mailbox/newspaper box
5. Privacy fence
6. Street
7. Bird feeding area
8. Sitting area
9. Water garden
10. Small tea table with two chairs
11. Shrub

Paths

Often-Used Routes:

P-1 Path from driveway to front door: Should be as direct as possible for fast, sure-footed route.

P-2 Path from front door to mailbox: Should be straight and direct for those occasions when a quick route is desired.

P-3 Connecting route from P-1 path to utility meter: Should be clearly defined for meter readers.

P-4 Connecting route from front door to bird feeding station: Should be simple and direct with good footing and wide enough to haul supplies as needed.

Optional Paths:

P-5 Alternate route back to house from mailbox: A curving path makes the garden seem larger.

P-6 Curve the path around shrubs to create a sense of mystery and anticipation.

P-7 Widen the path to slow footsteps; a narrow path makes people walk faster.

P-8 Vary materials for different feeling: Flagstones around a water garden mimic stepping stones in a pond for a casual, fun approach.

P-9 Avoid dead ends unless there is a sitting area at the end of the path. Plan paths so that there are plenty of options as to which way to go.

P-10 Instead of making paths meet at right or sharp angles, curve the corners widely to allow easy travel in either direction. Curve only one corner if you want to direct traffic toward that side.

P-11 Place a particularly interesting specimen plant at wide intersections in the path. Wide places naturally invite lingering, so spice them up with something neat to look at.

P-12 Log rounds can bridge a short distance between paths—without interfering with garden planting design. They unobtrusively guide visitors to "squeak through" a place.

One continuous loop through the garden is the minimum when it comes to paths. A single, dead-end path that makes you retrace your footsteps coming and going isn't nearly as much fun as a path that loops around and lets you keep going without doing an about-face. I avoid dead ends unless there's a sitting area at the end of the path.

To guide family, friends, and visitors to the main paths through the garden, mark these paths with a simple ornament. Anything that draws attention to the beginning of the path will work. These are great spots to use special favorites from your own collection or any of the garden ornaments sold in shops and catalogs. Here are a few suggestions:

- A pair of rocks flanking the entrance.
- A metal ornament with black, brass, or verdigris finish. I like to use a metal stick hummingbird, butterfly, or other natural subject. Many artists are beginning to turn out wonderful, whimsical designs, like oversize praying mantids and dragonflies, made of copper that will weather beautifully.
- A small metal or concrete frog, turtle, or other animal, perched on a rock or settled in mulch.
- A special rock or a small grouping of specimens: agate, crystal, volcanic lava, or whatever you've collected.
- A cast stone or concrete Japanese lantern straddling a thick, flat rock.

The width and shape of your paths have great psychological effect. A narrow path flanked by shrubbery will make passersby hurry through. Though we may not realize it consciously, our animal instincts sense danger in such close quarters. Widen a path, and footsteps slow like magic.

Continued →

To make your garden seem larger, curve the paths. Sketch your plan on paper first, and you'll be surprised at how much mileage you can get out of a curving trail.

I like to allow plenty of options as to which way to go, so I include intersecting paths to give a choice of direction. Human feet don't turn corners easily, so instead of making paths meet at right or sharp angles, I widen the inside corners at intersections into curves to allow easy travel in either direction. Curved corners can be useful, too, if you want to turn traffic in a certain direction: By curving just one inside corner, you encourage travelers to move in that direction.

When I have a plant I want to show off, I widen the path into a bulge at that point. That's an effective way to slow feet, and it lets my special plant get more attention. Intersections also get a lot of attention, so they're a good place to plant your favorite specimens. Of course, I look at every plant in my garden every morning, so these machinations are more for visitors than they are for me.

I find a path of carefully laid stone a distraction, but I like to keep a sense of fun in my garden by using log rounds or stepping stones to leapfrog short distances. Stepping from one to the other makes me remember my days in the woods as a kid, when I'd squeak through bushes and undergrowth by stepping from one rock or log to another. These types of stepping stone paths are often less obtrusive than full-scale trails, so they don't interrupt the integrity of the planting design or affect the mood of the garden.

PATH MATERIALS

Some years back, a friend brought two natives of Hong Kong to visit us. The girls were high school teenagers who'd lived in the city all their lives. As we led our guests out to the table in our shady yard, they began giggling and talking excitedly to each other, meanwhile walking very oddly, with high, bouncing steps.

Was something wrong? We wanted to know. They were extremely shy, but finally they explained. Never before, they said, had they walked on grass. All they knew beneath their feet was the concrete of city life.

I tried to give them a word to describe what they were feeling, but everything I thought of—springy, spongy, firm but with a give—failed miserably. What English word can convey that delicious feeling of walking on natural grass? For that matter, how could you describe all of the sensations of walking a forest path, or a river trail, or a sandy beach? You can't come close to summing up all of the things that make an ordinary day in nature such an incredible experience. It's not just the feel of humus or turf beneath your feet, but the scents in the air, the sounds of birdsong, the play of sun and shadow.

Why surface a path at all? You may not need to. *Au naturel* paths of fallen leaves, pine needles, softly packed earth, or sand are perfectly suitable. But in my area, rains can turn an earthen path or fallen leaves into slippery city. I like sure footing beneath my feet, so I use wood chips on my paths. In a meadow garden or other sunny area, you can use wide mown grass trails as paths, or you can plant traffic-tolerant groundcovers like clover or chamomile.

Natural materials are best for natural landscapes. Wood chips are my path surface of choice for a woodland or shade garden. In these settings, they look as natural as a deer trail. They're low-cost (or free), and they only need to be renewed once every couple of years in most cases. Installation is simple: Just rake them into a layer 4 to 6 inches deep. They'll pack down under foot traffic. And maintenance couldn't be easier: Just renew them as needed—usually once or twice a year.

If you're not fond of wood chips, or if you live where trees are scarce, turn to other natural materials. Your choices will vary depending on where you live and what the terrain is like.

The Fragrant Path

Forgiveness, an old saying goes, is the sense of the violet that clings to the heel that crushed it. I find walking on flowers a little sadistic but I don't have any compunction about walking on fragrant herbs.

Creeping thyme is hardy and easy to grow, and it spreads like mad. Roman chamomile is almost as obliging. (Don't confuse the mat-forming perennial Roman chamomile with German chamomile, a kneehigh, airy annual.) Both plants are great to work into an existing grass path. Or you can put down a wood-chip path and transplant starts of the herbs here and there along it, Walk carefully for a season, and the herbs will fill in nicely. Both release a delicious fragrance when you tread on them, and they quickly bounce back if traffic isn't too heavy.

Don't try herbs on the main path to your house because their leaves will quickly get worn off. But even on the busiest thoroughfare, you can plant chamomile, thyme, or creeping pennyroyal at the edges, where they can send aromatic tendrils out into the traffic.

Building a Stone Wall

Having grown up in the Northeast, where stones are a natural harvest every time you turn the soil, my attitude toward them was as objects of annoyance rather than objects of beauty. I remember reading a national columnist's advice for naturalizing a yard full of daffodils: Loosen the soil to a depth of 2 feet, she advised, so that you could plunge your arm into the soil up to the elbow. Right, I scoffed, thinking of the skinned knuckles and broken wrist that would result if I tried to do that. Planting bulbs for me was more likely to be a matter of working with a dandelion digger and making narrow slits into the earth to nestle the bulbs into.

I admired stone walls, of course, but it never occurred to me to try to make one until we bought the old quarrymaster's house at a former slate quarry. Suddenly I had tons of rock to play with, big slabs of charcoal-colored slate 6 inches thick or better.

"With such a ready supply just a short wheelbarrow's drive from my garden, I planned my first stone wall, a 30-inch-high, curved retaining wall for a raised bed of herbs and perennials.

I couldn't believe how easy it was to make. Though I boned up by reading step-by-step how-to books, the actual process was as instinctive as building with my then-two-year-old's set of wooden blocks.

BEFORE YOU BEGIN

If you're not blessed (or cursed) with an abundance of natural stone on your own place, you'll have to order it. Check the Yellow Pages under "Stone-Natural" to find dealers. Before you order, plan a visit to the dealer's yard to see samples of the rock. You can expect to pay about $100 or more a ton for natural stone. You'll want flat stones for easy stacking.

I was lucky to have my own rock quarry because I seriously underestimated how much rock I'd need. A couple of formulas from professionals will make it easy for you to get a handle on how much stone you need.

Use these formulas to get a ballpark estimate to see if the project fits your budget, then double-check your needs with your stone supplier. The final amount will vary somewhat depending on the type and size of the stone you select.

If your dealer sells stone by weight, your figuring is simple. Allow a ton of stone for every 25 square feet of the wall's face. To figure square feet, multiply the height of the wall times its length. A 20-foot-long wall that's 3 feet tall equals 60 square feet of face (60 ÷ 25 = 2.4 tons of stone). Allow a little extra for waste, and order 2.5 tons of stone.

If your rock yard sells by the cubic yard, you'll need to do a bit more calculating:

1. Measure the length of your intended wall in feet. Let's say 20 feet, as an example.
2. Multiply by the intended height and width. We'll make our imaginary wall 3 feet high and 12 inches wide, so 20 feet x 3 feet x 1 foot = 60 feet.
3. Divide by 27 to get the number of cubic yards, which is the measure by which stone is often sold by the truckload. In our case, 60 ÷ 27 = 2.222.
4. Add 5 percent to your cubic yard total to allow for waste—those stones that you can't gracefully fit into the wall. 2.222 x 0.05 = 0.111.
5. Add your totals from Steps 3 and 4 together: 2.222 + 0.111 = 2.333, or rounded up, 2.5 cubic yards of stone.

Garden Accents

Along with the gardening renaissance has come an explosion in art for the garden. No longer do you have to search out ornaments from antique shops. Now anybody with a phone can order all kinds of finishing touches, from Victorian gazing globes to resin gargoyles that look like they just dropped in from Notre Dame.

Remember that garden ornaments are like jewelry: It's better to have one great piece than it is to pin a dozen cheap sparklers to your bosom (though there are times, I admit, when I'm in the mood for flash). Instead of lining the edges of your pond with a dozen facsimile frogs, turtles, and bunny rabbits, why not invest in a statuesque, life-size heron?

Of course, part of the fun of a natural garden is that you can hide ornaments for visitors to come upon unawares. A concealing curve in the path is a great approach to a special piece of garden art. I have a small collection of concrete frogs (some not in the best of health) that I like to move around during the season. My son likes to discover their new hiding places. Sometimes I lose track of one or another of them myself, and then it's fun to come upon them again.

Keep in mind that any object made by human hands is automatically an attention-getter in the garden. Birdhouses, butterfly shelters, and bat houses are often focal points in the natural landscape. So use them sparingly but well—you, your visitors, and wildlife will all enjoy them.

Back-Saver

You've heard it before, and it's still good advice: Lift with your legs, not your back. Bend your knees and crouch to pick up stone, boosting its weight with your heavy-duty thigh muscles when you lift. Don't bend at the waist, even though that seems easier, unless you want a long vacation at the chiropractor's office.

Edgings

Fern Marshall Bradley

Edgings are picture frames for your landscape. They accent individual sections and help tie sections together into a unified whole. They also reduce mowing and trimming by preventing lawngrass from creeping into your perennials and by giving you a clean edge to trim up to.

Decorative edgings. Garden centers offer diminutive picket fencing, rustic log ends, terra-cotta tile roping, and other attractive edgings. Collectors may enjoy making their own edgings from large seashells, river pebbles, or salvaged bricks. If you're patient, try the timeless elegance of a miniature clipped box hedge. For a quicker version, try a hedge of tiny-leaved bush basil plants, or an edging made of willow shoots.

Continued ➔

Build a Hundred-Year Wall

Building a stone wall can sound more intimidating than it really is. Keep in mind that even a petite wall can carry a lot of weight, both visually and literally. But it's really not hard to build. I revamped my mother's always-eroding front garden one year by carving a path at the bottom of her steep bank and setting in a stone wall about 18 inches high to hold the soil. I added a second retaining wall about halfway up the slope, making it just two stones high and one stone thick. The whole project took only an afternoon, and the stone "walls" set off her collection of ferns and wildflowers beautifully.

Take your time when building—you want this to last forever. The only tools you'll need are a chisel and a stonemason's hammer to whack off occasional protruding bumps that keep the stones from lying smoothly. A level is optional, but don't forget safety goggles and a long-sleeved shirt and pants so that you don't get nicked by flying chips.

Step 1: Mark off the area for the wall with stakes and string, then dig out existing soil and turf to a depth of 6 to 12 inches. If your wall will have soil behind it, angle the back edge of this foundation so that it slants backward. Fill with coarse gravel.

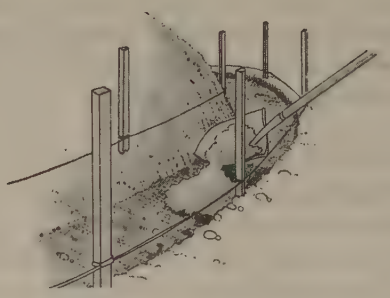
Step 2: Pick out some of your biggest, most level stones, and lay them on the gravel. If your stones are rectangular, lay them endwise so that the short ends are at the face. Make sure they're solid and level. You can eyeball the horizontal lay of your wall by using a piece of string tied to two stakes, raising it after each course of stone. Or you can use a carpenter's level. You're not aiming for perfect flatness, just a general impression of horizontal trueness. In other words, you don't want your wall to look like it's crooked. Fill in chinks between stones with small broken pieces or gravel. Ram them in with the end of a hoe. Pour 2 inches of soil over the base layer of stone so that it's easier to level the next layer.

Set the next course of stone, working by the one-over-two rule. This time, you can set rectangular stones so that their longest side is toward the face, except at the ends of the wall. At both ends of the wall, set a rectangular stone with the short end facing front, as on the bottom layer, digging it into the earth behind the wall for extra stability. It also adds strength to set in a stone this way about every 6 feet along the wall. If your stones are wobbly, shim them with small pieces of rock until they feel solid.

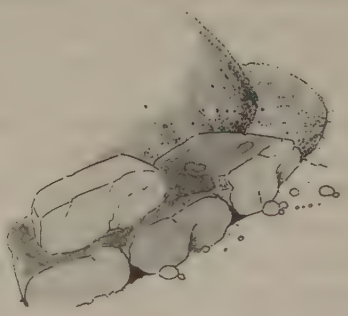
Step 3: If your wall is built against a slope, fill in behind the wall after each layer with broken stone and soil, packing it in solidly with your trusty hoe handle. Continue laying courses in this manner. Put aside pretty, flat, large stones as you find them to save for the top layer.

Step 4: For the top layer, lay the stones as you did for the foundation, with their short ends facing the front. Finish packing the space behind the wall, and fill in with soil around the wall as you like.

1.



2.



3.

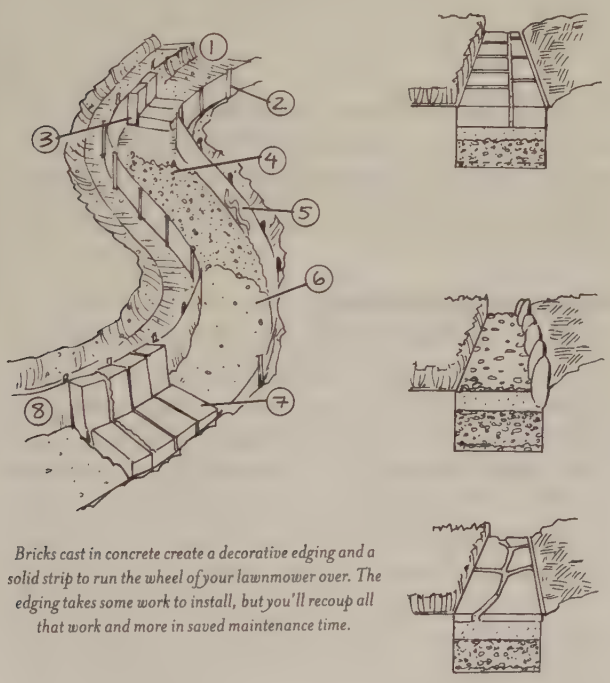
4.

Hard-working edgings. For quick results, use a commercial black plastic edging made up of interlocking 8-inch-wide pound-in sections. It's easy to install, but you'll need to push it back in each spring because it tends to frost-heave. Roll edgings work well also. Spend a little extra when you buy plastic edging and get one guaranteed not to crack in heat or cold.

Cast-in-place concrete edging with a mowing strip and a decorative edge of brick or stone, like the one shown below, is very convenient and durable. The concrete base prevents the bricks or stones from falling over and from frost-heaving. Choose bricks or pavers designed to be walked on. If your ground freezes in the winter, choose severe-weathering brick.

Mixing your own ready-mix concrete isn't hard; just follow the instructions on the bag. To decide how many bags you'll need, multiply the width of your edging by its depth and length. This will give you its volume in cubic inches. Each ½-cubic-foot bag of concrete mix will fill 864 cubic inches.

When you work with concrete, wear tough gloves. Wash off any concrete that gets on your skin right away to prevent chemical burns. Don't pour more concrete base at one time than you can finish before it hardens.



Bricks cast in concrete create a decorative edging and a solid strip to run the wheel of your lawnmower over. The edging takes some work to install, but you'll recoup all that work and more in saved maintenance time.

Step 1. Dig a 9"-deep, flat-bottomed trench. The trench should be 8" wider than the width of the edging.

Step 2. Hammer in wooden stakes and fasten 8"-high hardboard strips to them to make a form for the edging. Check with a measuring tape as you work to be sure forms are parallel.

Step 3. Set a few loose bricks in place to check that the form is correct. Pack soil into low spots to level the bottom of the trench.

Step 4. Pour a 4" layer of fine gravel into the trench between the forms, and use your feet or the end of a 2 x 4 to pack it smooth.

Step 5. Grease inside edges of forms with vegetable shortening so they'll be easy to remove after edging is laid.

Step 6. Pour 2" of prepared ready-mix concrete over the gravel; smooth it with a leveler.

Step 7. Set bricks in still-soft concrete; slant flat bricks slightly outward to shed water. Coat the forward edge of each brick with a ¼"-thick layer of ready-mix mortar. Use a putty knife to remove excess mortar and to cut a groove in each joint.

Step 8. Wait a few hours once bricks are in place. Then take off forms, fill in soil, and replace turf. Wait a few days before putting weight on the edging.

Note: You can also make edgings from patio blocks, river rocks, or slate.

Paths

Fern Marshall Bradley

The minimum width for a foot path is 18 inches. For a path that's used daily, 3 or 4 feet is a more suitable width. On a 5-foot path, two people can walk abreast even if plants drape romantically over the path's edges.

Choosing materials

Paths that will take daily use should be smooth, solid, and nonslip. Poured concrete, asphalt, or large slabs of quarried stone are your best choices. Firmly set bricks or pavers or wooden walkways will also do but are harder to keep free of snow.

Loose material such as gravel, crushed shells, or sand makes a fine path for more leisurely strolling. Wood chips, bark chips, sawdust, mown grass, stepping-stones, and even bare soil in some climates serve well for lightly traveled, informal paths and are easy on the budget.

A brick path set in sand, like the one shown on the following page, is easy to build and will stand up to all climates. If you live in an area where the ground freezes in winter, use severe-weathering bricks.

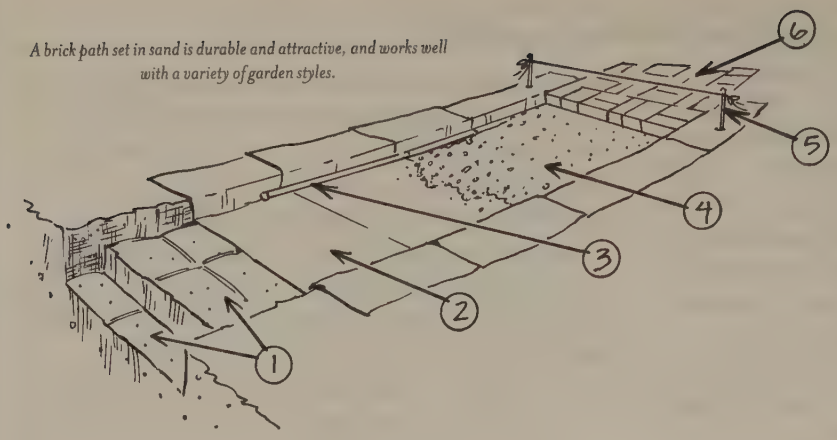
In regions where the ground never freezes, you can skip the gravel layer as long as your soil drains well. Dig the trench 4 to 6 inches deep, spread landscape fabric over the soil base, and add 2 to 4 inches of sand. If your design involves cutting bricks, get the professionals at the building-supply center to show you what tools you'll need and how to make cuts safely.

Step 1. Dig a flat-bottomed trench 12" deep and about 5' wide.

Step 2. Pack in a 5"-deep layer of compactable gravel. Then add and tamp more gravel to create a 9" compacted base.

Step 3. Spread landscape fabric over the gravel, overlapping the pieces.

Continued →



A brick path set in sand is durable and attractive, and works well with a variety of garden styles.

Try making a brick "rug" in the center of a fragrant perennial planting for a seating area. Use the same techniques as you would for a brick path, but make an oval or rectangular frame instead.

Step 4. Lay two strips of rigid plastic edging along the sides of the trench, and use galvanized spikes to anchor one strip in place.

Step 5. Test-lay some bricks to determine exactly where to position the second edging strip. Anchor the second edging strip, keeping the two strips parallel.

Step 6. Spread 1" sand, water it well, and tamp it solid. Smooth out the surface with a leveler (a second person helps here). If the brick pattern involves straight lines, stretch a string guide now as a starting point.

Step 7. Begin laying bricks. Tap each brick sharply with a rubber mallet to set it firmly in place. Press bricks tightly against edging strips. Leave 1/8" gap between bricks.

Step 8. Use a leveler to check whether bricks are even. Tap down any high ones. Brush loose sand into the gaps until they are 1/4" short of being full. Water with a fine spray. From this point on, you can walk on the bricks.

Step 9. Fold fabric over bricks and backfill the remaining gap with soil. Snip off the excess fabric 1/2" below the path surface.

Stone Retaining Walls

Fern Marshall Bradley

By building a stone retaining wall, you can turn a tough-to-maintain slope into a productive and beautiful garden. A dry-laid (mortarless) stone wall is an excellent project for a beginning wall builder.

It's best not to try building a wall more than 3 feet high. If you have a slope that would require a high wall, you have two options: Either split the slope and build two walls with a level planting terrace between them, or hire a professional to build one high stone wall.

Step-by-Step Wall Building

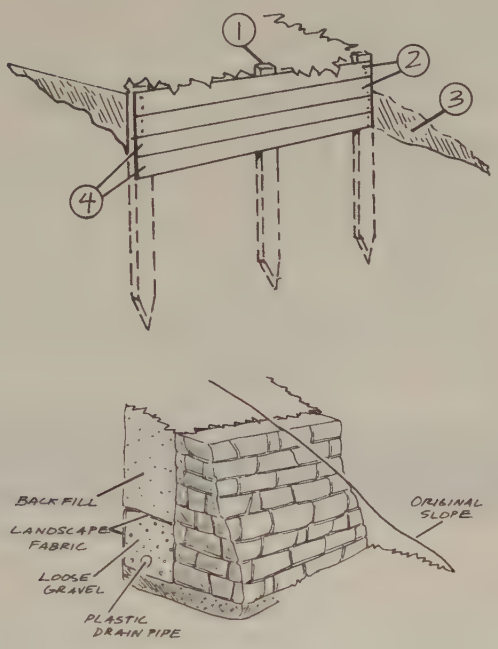
If you don't already have an abundance of stones on your property, you can buy natural and quarried stone, or even manmade interlocking building blocks. To find sources, look under "Stone" in the yellow pages of your telephone directory. If you have stone delivered, have it dumped as close to the worksite as possible, preferably with about half of the load on the uphill side of your wall and half downhill.

Take it easy when you're working. Always lift with your legs, not your back; and if you can't lift a stone easily—don't lift it. Use a couple of stout iron bars to roll and pry stones that are too big to lift, and use sturdy wooden ramps to get them up onto the wall as you build.

Here's how to build a stone retaining wall.

1. Use a spade or shovel to dig out a flat area at the base of the slope. Cut out a flat area equal to the thickness of the planned wall, plus 1 foot more. Pile the excavated soil up slope, or somewhere else out of your way.
2. Mark the outline of the outside face of your wall in the dirt. (Keep in mind that there's no law that walls have to be

A dry-laid stone wall works well as a retaining wall at the bottom of a slope. Perforated plastic pipe positioned behind the wall promotes good drainage.



Step 1. Pound posts into the ground in a line along the area you want to terrace. Leave 9" exposed at the top.

Step 2. Nail two rows of 1 x 4 boards along the tops of the posts.

Step 3. Dig the soil out downslope and pile it above the wall to expose another 9" of post.

Step 4. Nail two rows of 1 x 4s to the newly exposed parts of the posts.

straight.) Then mark a second line behind the first, one foot back from the rear edge of the wall. For example, if your wall will be 1½ feet thick, mark the second line 2½ feet back from the first. Two flexible hoses work well for marking out smoothly curving walls.

3. Dig a 12-inch-deep, flat-bottomed trench between the two guidelines you marked. Don't dig deeper than 12 inches—your wall should be built on undisturbed soil.
4. Line the trench and 2½ feet up the exposed earth face with strips of landscape fabric, overlapping adjacent strips 6 inches. Anchor the fabric temporarily to keep it in place.
5. Pour a 6- to 8-inch layer of compactable gravel into the trench and tamp it down well. Fold the fabric in over the gravel at the outside edge of the trench.
6. Spread out all the stones so you can see what you have to work with. Then, start laying up your wall. Place the largest stones first, following the outer contour of the trench. Adjust the underlying gravel so the stones sit firmly.
7. Continue adding layers, choosing the stones carefully. Ideally, each stone should span the joints in the layer below it, from front to back and/or from side to side. Overlapping the stones strengthens the wall. Also, make sure the stones sit firmly. If necessary, slip small, flat stones under the larger ones to remove any wobble.
8. When the wall is about 1 foot high, lay a length of 4-inch-diameter perforated plastic pipe on the gravel behind it for drainage. The pipe will exit the wall at a corner. Or, if your wall will not have exposed corners, use an elbow to direct the pipe out through the front of the wall. Cover the pipe with 1 foot of loose, coarse gravel and fold the landscape fabric over the gravel toward the wall.
9. Lay more layers of stone, making the wall a little narrower with each layer (about 2 inches for every foot of height). Keep the back of the wall vertical, and taper the outside. Use large, flat stones for the top layer, then backfill in behind the wall with the soil you dug out of the slope.

Adding Height with Trellises and Arbors

Fern Marshall Bradley

A yard full of perennials can look like a flat sea of plants. To give your landscape depth, variety, and some soothing shade in the long term, you'll want to include shrubs and trees in your design. You can also use arbors, pillars, and other vertical features.

A rustic arch. It's easy to add height with a rustic arch made from cut saplings, like the one illustrated on the next page. You can use hickory, oak, or maple saplings. Cedar or locust would be even better because they are more rot-resistant.

To build the arch, you'll need 4-inch-diameter saplings for the uprights and crossbars. Cut the four uprights 6½ feet long; cut two 18-inch crossbars and two 12-inch crossbars.

For the ridge pole and rafters, use 2½-inch-diameter saplings. The ridge pole is 18 inches long; the four rafters are each 5 feet long.

Last, you'll need 1½-inch-diameter saplings for the lattice; cut 12, each 4 feet long.

The arch is held together with 8-, 10-, and 12-penny common nails.

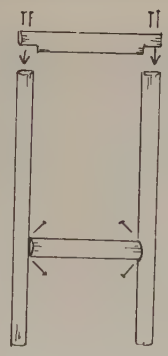
Step 1. Assemble the two side panels. Drill two holes through the uprights at each joint, insert 12d nails, and hammer them firmly into the crossbars.

Step 2. Add lattice braces. Lay a lattice piece across the panel. Mark where to cut and trim with a saw. Drill two holes through each end, insert 10d nails, and hammer them firmly into the uprights.

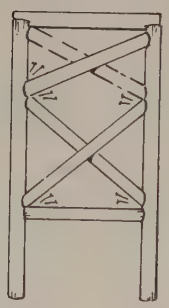
Continued ➔

To add height quickly while you wait for newly planted trees and shrubs to grow, try using simple pillars, arbors, and fast-growing vines and grasses.

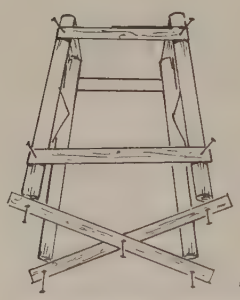
A wooden arch is a lovely rustic feature for a perennial garden. You can build one in a single weekend, using only a saw, hammer, and drill.



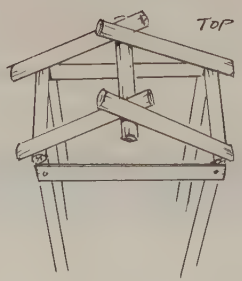
1.



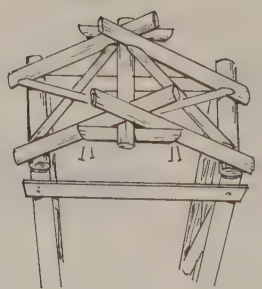
2.



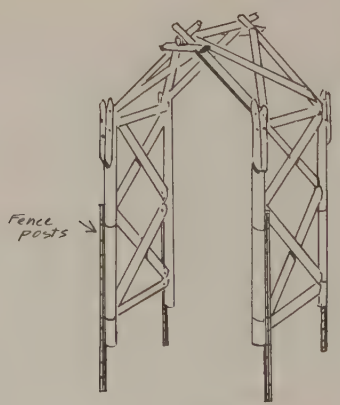
3.



4.



5.



6.

Step 3. Brace the side panels. Nail scraps of lumber between the side panels to hold them 4 feet apart, as shown. These braces stay on until the arch is installed.

Step 4. Add the rafters and ridge pole. Drill and nail two rafters to the uprights and each other. Position the ridge pole, and drill and nail it firmly to the rafters. Then attach the second pair of rafters.

Step 5. Attach the roof lattices. Use the same procedure as for the side lattices. Use the scrap ends of the lattice pieces to reinforce the arch joints. Drill and nail them on firmly with 8d nails.

Step 6. Set the arch on concrete pavers (to keep the wood dry and prevent rot). Anchor the arch with 4' metal fenceposts driven into the ground next to each of the uprights.

Outdoor Rooms of Green

Some folks like to set up folding chairs on the front lawn and watch the traffic go by. But most of us find ourselves hanging out in a more private part of the yard, one that offers some sense of enclosure. A traditional porch does that splendidly, of course, and with a little planning and planting you can do the same somewhere on your property. This spot is apt to catch the sun at the appropriate time of day, along with shade when necessary. It could offer a view to the front of the house so that you can keep an eye out for arriving visitors, or to the backyard so that you can monitor the kids' activities. And you might want to create the effect of walls with hedges, rock walls, or even just a row of potted plants. Add comfortable seating (a bench without a back might not qualify) and move right in.

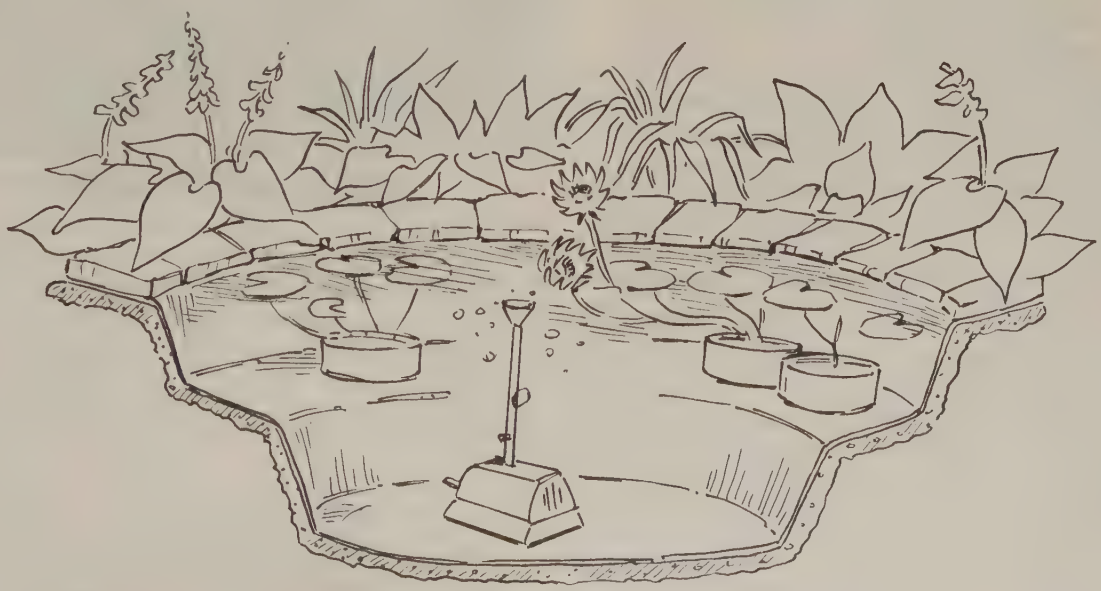
Lighting Your Landscape

Fern Marshall Bradley

If you have a busy lifestyle, you may rarely see your perennials during the workweek. Wouldn't it be nice to sit outside and enjoy your flowers long after the sun sets? You can do it by adding lighting to your perennial plantings. You can position lights to illuminate a bed from either the front (spotlighting) or above (downlighting), or you can create special, subtle effects by backlighting or lighting them from below (uplighting).

With a simple do-it-yourself 12-volt lighting system, it's surprisingly easy and affordable to light up your landscape. You can buy simple kits with a transformer that plugs into a regular household outlet. In some systems the lights even snap on or off the wire with no tools, so you can move them around to create different effects.

A cross-section of a water garden reveals the plastic liner that holds the water in, and a submersible pump that creates the fountain at the water's surface.



Continued

A Straight and Simple Stone Path

What You'll Need

Rectangular flagstones of three or more different lengths

String and stakes

Square-bladed shovel

Work gloves

Work shoes

Much of the challenge of installing a flagstone path is getting those odd-shaped puzzle pieces to fit. They're heavy, sharp-edged, and seem to resist snuggling close to one another. You can make matters easier for yourself by visiting a home and garden center or stone dealer and buying rectangular stones. Be equipped with the overall length you need, so that you can order pieces of varying lengths that will do the job. If you have the choice of different thicknesses of stone, the thinner stuff is easier to move and less expensive, but it may be more prone to cracking over time.

Because rectangular stones are cut with some precision, the cracks between them are smaller and weeds have less of an opportunity to establish themselves along the walk. In fact, you can skip the usual step of laying down a bed of sand before putting the stones in place, although it may be easier to provide a level layer with sand than with stony or clumping soil.

1. Lay out the walk with string stretched between two stakes tapped into the ground. If you place the string outside of where the walk will go, it'll be less likely to get in your way as you dig the trench. Alternately, you can lay out the string along both edges of the path's intended course and make lines with aerosol paint.
2. Dig a trench for the walk so that the top of the stones will be at ground level.
3. Wearing work gloves, put the stones in place. Vary their lengths randomly along the walk. If the last stone isn't the right size for the length of the walk, you can ask your supplier to saw it. Or do the job yourself with a circular saw and masonry blade, wearing safety glasses.
4. Put your weight on the walk to test it for stability. Tuck small stones and soil under the stones as necessary to level them. Finally, place soil along the outside edges and tamp it down. In time, grass will spread into this new strip of soil, making the walk look like it has been there for years.

PLANT PROJECTS

Build a Super Compost and Soil Sifter

Vicki Mattern

For starting seeds and filling pots, you need "screened compost." That's where a compost sifter comes in handy. The sifter is a screening box that is designed to fit right on top of your wheelbarrow or garden cart, so that you can fill it with fine-textured compost and then toss the larger remnants back into the compost pile for further cooking. You can construct this useful gadget in just an hour for a cost of less than $15.

MATERIALS

2 untreated 1" x 12" x 8' boards

2-inch galvanized deck screws, or 2-inch galvanized or aluminum nails

¼-inch or ½-inch metal hardware cloth

Heavy-duty staple gun and staples

1. Measure the inside distance between the sides of your wheelbarrow or cart—this measurement will determine the size of your sifter's opening.
2. From each board, cut one 24-inch-long piece and one 36-inch-long piece. From each of the 26-inch leftovers, cut one ¾-inch-wide retaining strip to help hold the screen in place. (Use a jigsaw to cut handholds. Use a router or sandpaper to smooth the edges of the holds.)
3. Screw or nail the four sides together at the corners.
4. Using the staple gun, staple the hardware cloth to the bottom edges. (For potting soil, use ¼-inch hardware cloth; for other garden uses, ½-inch cloth is fine.)
5. For the bottom of the sifter, cut two 24-inch-long filler pieces from the leftover boards to cover the parts of the box that will extend beyond the sides of your wheelbarrow or cart. (Use the measurement from Step 1 to determine the size

Continued ➔

of the pieces.) Also cut ¾-inch-wide guide strips from the leftover pieces to hold the sifter tightly in place on your cart. Screw or nail the filler boards into place and then staple the screen to them. Now screw or nail the ¾-inch pieces; attach the retaining strips to the long edges of the box; and attach the guide strips to the edges of the filler boards so they will rest against the facing sides of your wheelbarrow or cart and hold the sifter in place.

Making a Barrel Composter

Barbara W. Ellis

For small composting operations, the barrel composter is ideal. The composter is easy to build and use. The compost is easy to turn by rotating the drum.

TOOLS REQUIRED

Electric drill

Saws (saber saw with metal-cutting blade and handsaw or circular saw)

Screwdriver

Pliers

Paintbrush

MATERIALS

Lumber-Cut List

You'll need to cut lumber into the following lengths. Use pressure-treated lumber or, if you prefer, untreated pine painted with a preservative or flat black paint. It's best to measure and then cut the pieces as you assemble them to be sure they fit together correctly.

4 pcs. 2 x 4 x 40" (legs)

4 pcs. 2 x 4 x 29¾" (frame horizontals)

2 pcs. 1 x 3 x 40-⅝" (cross braces)

4 pcs. 1 x 3 x 23¾" (corner braces)

2 pcs. ¾ x 7½"-diameter wood circles (bearings)

2 pcs. ¾ x 2¾"-diameter wood circles (bearings)

Hardware

1 55-gallon drum (composter)

2 pcs. 1½ x 2" hinges

1 small hasp

1 pc. ½ x 40½" steel rod

8 pcs. ¼ x 1¼" stove bolts

12 pcs. ¼ x 1" stove bolts

28 pcs. 1½" #10 wood screws

1 pint black rust-retardant paint

1. Obtain a 55-gallon drum that has not been used for toxic chemicals. (Paint barrels are ideal.)

2. Drill a ½-inch hole in the exact center of both ends of the drum to accommodate the ½-inch steel rod. Make a simple gauge to find the center by cutting a 6-inch diameter circle out of heavy cardboard or wood. Mark the exact center of the circle and cut out a 90-degree wedge. Attach a piece of wood so that one edge bisects the cut-out wedge. Hold the gauge with the cut-out edge against the edge of the drum. Draw a line where the piece of wood bisects the end of the drum. Move the gauge 90 degrees and draw another line. The intersection of these lines will be the exact center.

3. Draw the lines for the barrel opening, rounding the corners slightly. Drill a ¼-inch hole on one line to make a starting place for the saber saw. Cut through the barrel, following the line. If the barrel has ribs, cut a 1-inch vee notch on each rib to facilitate opening the door. Attach the hinges and the hasp to the barrel and lid with ¼-by-1-inch stove bolts.

4. From ¾-inch pine, cut two 7½-inch-diameter circles (bearings) and two 2¾-inch-diameter circles. Drill a ½-inch hole in the center of each and apply glue to the 2¾-inch circles. Glue each 2¾-inch circle to a 7½-inch one. (It's a good idea to temporarily slip them over the ½-inch steel rod and clamp them.) After the glue has dried, remove the bearings, insert the rod through the barrel, and assemble. Use four ¼-by 1¼-inch stove bolts in each bearing to bolt them to the drum.

5. To build the support frame, use a corner lap joint to fasten the legs to the horizontal pieces. (To make a corner lap joint, remove one-half the thickness of the stock to a length comparable to the width of the stock on the ends of both pieces to be joined.) Use two 1½-inch #10 wood screws in each joint. Cut grooves (dadoes) on the legs 23 inches from the bottom to fit the 1-by-3-inch cross braces. Cut 45-degree angles at both ends of the 23¾-inch-long corner braces and attach across corners with 1½-inch #10 wood screws. Cut a ½-inch notch in the center of each top horizontal piece to accommodate the rod.

6. Drill several rows of ¼-inch holes along the bottom of the barrel underneath the door opening to eliminate excess moisture. Paint the barrel unit inside and out with black, rust-retardant paint.

Making a Three-Bin Composter

Barbara W. Ellis

TOOLS REQUIRED

Electric drill

Saw (circular saw or handsaw)

Hammer

Pliers

MATERIALS

Lumber-Cut List

Cut lumber into the following lengths. Use pressure-treated lumber or untreated pine painted with a preservative or flat black paint. Measure and cut the pieces as you assemble them to be sure they fit together correctly.

For Bins

1 pc. 2 x 6 x 108" (center joist)

2 pcs. 2 x 6 x 30" (headers)

2 pcs. 2 x 6 x 111" (outside joists)

2 pcs. 2 x 6 x 14¼" (brace blocks)

4 pcs. 1 x 6 x 33" (short floor boards)

8 pcs. 2 x 6 x 41½" (corner posts)

24 pcs. 1 x 6 x 36" (partition boards)

6 pcs. 2 x 2 x 34" (inside door tracks)

2 pcs. 2 x 2 x 35½" (outside door tracks)

1 pc. 2 x 6 x 96" (cut to fit for post blocks)

14 pcs. 2 x 6 x 34½" (floorboards)

6 pcs. 1 x 6 x 111" (backboards)

18 pcs. 1 x 6 x 35½" (door slats)

3 pcs. 1 x 3 x 35½" (door slats)

For Lids

18 pcs. 1 x 6 x 37" (lid boards)

3 pcs. 1 x 2 x 36" (front battens)

3 pcs. 1 x 2 x 34" (back battens)

2 pcs. 1 x 2 x 11¼" (hatch battens)

2 pcs. 1 x 2 x 22" (header batten)

HARDWARE

For Bins

22 pcs. ¼ x 3½" carriage bolts with nuts and washers

galvanized nails 16d

galvanized nails 8d

For Lids

6 strap hinges 8" (lids)

2 strap hinges 4" (hatch)

4 lengths jack chain, approximately 36" each

8 heavy eye screws

4 snap hooks

1 box 1¼" #6 galvanized screws

BUILDING THE BINS

1. **Base.** Nail a header to each end of the center joist, using 16d nails. Nail the outside joists, front and back, across the ends of the headers. Nail the brace blocks in place between the joists. Locate and nail the four short floorboards across the joists where the partitions will be located, using 8d nails.
2. **Partitions.** For each of the four partitions (two outside and two inside), nail six partition boards to connect two corner posts, spacing them evenly. Nail the inside door tracks to the partition boards, 1 inch back from the corner posts. Nail the outside door tracks flush with the front of the two interior partitions. Position the assembled partitions—one on each end of the base and one on each side of the interior compartment; drill and bolt the corner posts to the outside joists.
3. **Post Blocks.** Cut the 2 x 6 x 96" post block board in three pieces, to fit snugly between the bottoms of the front corner posts. Bolt the post blocks in place, flush with the floor surface.
4. **Floor.** Space the floorboards evenly across the joists and nail them in place. There will be five for each of the two end compartments and four for the middle compartment.
5. **Back.** Nail the backboards in place, covering the back corner posts.
6. **Front.** Feed door slats horizontally into the door track.

BUILDING THE LIDS

1. **Lids.** Construct two of the three lids. Using a drill and galvanized screws, fasten six lid boards to the front and back battens; allow about ½ inch between boards. Each lid will measure 36 inches across. Construct the third lid in the same manner, but leave out the two middle boards.
2. **Hatch.** Fasten the hatch battens to the two remaining lid boards, one batten about 2 inches from the end of the boards

Continued →

and one batten 18 inches from the same end. Fasten the header batten to the boards, 20 inches from the end, just behind the back hatch batten. Cut between the header batten and the back hatch batten to separate the hatch. Fasten the two remaining boards and the header batten to the partially constructed lid. Hinge the hatch to the lid.

3. **Finish.** Attach the three lids to the bins with the 8-inch hinges, so that they are centered over the compartments. Use eye screws to attach a chain to the bottom of the lids of the two end bins. Attach the chains on the inside edge at about the middle of the boards, on the side near the center partition. Attach chains underneath both sides of the lid of the middle bin. Mount snap hooks on the ends of the chains. Use pliers to attach eye screws to the bin partitions.

Build a Combo Composter

Barbara Pleasant

This easily assembled compost bin gives you a place to throw withered plants and food scraps, *and* you can use it to store your digging fork, spade, and other tools you reach for every day. Sturdy enough to resist invasions by the family dog, the Combo Composter is made from wooden pallets—also called skids—which are usually free for the asking at lumberyards or home improvement stores. Open spaces between the pallets' slats allow air to circulate freely, and the front comes off in seconds for easy access. By orienting the pallets so that the outer slats are parallel to the ground, you can slip tool handles through the open spaces at the top edge—or use them to hold one of the Easy Aerators. The finished bin is quite heavy, so it's best to assemble it near its permanent location. To get this bin to perform a fast disappearing act, paint it dark green or brown, and locate it in a shady spot.

You Will Need

Tools: Work gloves, marker, drill and bits, screwdriver, hammer, measuring tape

4 wooden shipping pallets

6 galvanized corner brackets

Twenty-four 1-inch wood screws

Four 4-inch-long pieces of scrap wood or furring strips

Eight 2-inch nails

Two 12-inch bungee cords (utility tie-downs)

1. Place the pallets that will be the sides of the bin on the ground, with the outer slats horizontal.

2. Attach a corner bracket to the edge of the top cross-board, another to the middle cross-board, and another to the second board from the bottom. To attach each bracket, hold the bracket in place with the bend in the bracket aligned with the outside edge of the pallet. Mark the screw holes, drill guide holes, and then screw the brackets in place. Repeat this procedure as you attach 3 brackets to the other side.

3. To attach the sides, rest the back pallet against a wall or tree, or have a helper hold it for you. Beginning with the center bracket, attach the side pallets to the back pallet the same way you did in Step 2.

4. To make compartments for tools, nail short pieces of scrap wood across the top of the back pallet at 6-inch intervals.

5. Position the bin in its permanent location. If necessary, dig out or add soil beneath the base to make the bin sit solidly on the ground.

6. Fill the bin with kitchen scraps, yard waste, and refuse from your garden. When you are not working the heap, close up the bin by securing the fourth pallet to the front with the bungee cords.

Make a Flip-Flop Compost Corral

Barbara Pleasant

This circular compost corral is incredibly easy to put together, yet it still gives you the versatility of a two-compartment bin. Gradually fill one wire-enclosed side with compostables, and when you're ready to dig in and begin some intensive turning to finish off the composting process, simply flip the bin to the other side of the central post, and start all over again.

The most challenging part of this project is installing the post. As long as the soil is moist, you should be able to pound a metal fence post into the ground by placing a piece of scrap lumber over the top and pounding away. If you prefer, install a wood post in a narrow posthole dug 18 inches deep. When installing either type of post, make sure there is 2 feet of free space on both sides. You can use the leftover lawn fencing for other projects, such as the Portable Trellis on page 761.

You Will Need

Tools: Wire snips, staple gun, hammer, pliers

1 roll of 3-foot-wide vinyl-coated 2 x 3-inch mesh lawn fencing

Two 48-inch-long 1 x 2 furring strips

One 6-foot-long metal fence post

1 small piece of scrap lumber

8 to 10 plastic cable ties

Two 6-inch lengths of 2-inch-diameter PVC pipe

1 thick rubber band

1. Use the wire snips to cut one 6-foot-long piece of fencing. To keep the fencing from rolling up as you try to cut it, it helps to have a helper hold the roll. Snip off protruding pieces of wire to create clean edges.
2. Use the staple gun to attach the furring strips to the cut ends of the fencing. Center the fencing so that about 6 inches of wood extends beyond the top and bottom of the fencing.
3. Cover the top of the fence post with the piece of scrap lumber, and pound it into the ground until the protruding metal wings near the base of the post are just below the soil's surface. To land sound blows, you may want to stand on a sturdy stool.
4. Using the plastic cable ties, attach the midpoint of the fencing to the fencepost at several points, with the bottom of the fencing flush with the ground.
5. On one side of the post, form a circle with the two sides of the fencing and mark the ground where the furring strips meet. Pound one of the pieces of pipe 5 inches into the ground, and then use pliers to pull it back out. Push a stick through the plug of soil to clear the center of the pipe, and then pound it back into the hole again, leaving the top ½ inch above the soil line. Install a second pipe sleeve the same way on the other side of the post.
6. On the first side you want to fill with compost, bring the two furring strips together and insert the bottom ends into the PVC pipe sleeve. Secure the top ends of the furring strips together with a thick rubber band.

Construct a Garbage Can Compost System

Barbara Pleasant

Contained compost systems are more challenging to manage compared to open piles. They are harder to aerate; they tend to be smaller (and thus slower to decompose); and it's easy to overwater the materials, so they become slimy. But if your town requires closed compost containers—or your dog likes to dig in an open pile—an enclosed system may be your best choice.

This easy system consists of two modified garbage cans with snap-on lids—an upright can for collecting materials, and a second can that sits on rolling casters for easy turning. To facilitate drainage, the bottom is removed from the collecting can. The rolling can includes interior baffles that help to mix the materials each time the can is turned. Having two containers that serve differing purposes helps to avoid the most common pitfalls of closed compost systems, and it makes the composting process more enjoyable, too. A bag of packaged compost is used to help get the compost off to a good start, or you can use compost you have made yourself.

You Will Need

Tools: Drill with bits, utility knife, hammer, measuring tape, screwdriver, adjustable wrench, garden hoe
Two 32-gallon plastic garbage cans with locking lids
One 20-quart bag of finished compost
Sixteen 2-inch nails
Two 36-inch-long pieces of 2 x 4 lumber
Two 15-inch-long pieces of 2 x 4 lumber
Two 18-inch-long pieces of 2 x 4 lumber
4 heavy-duty casters with wood screws
Four 30-inch-long pieces of 1 x 2 furring strips
Twelve 3-inch-long bolts with washers and nuts
One 18-inch bungee cord (utility tie-down)

1. To enhance aeration and drainage in the collection can, drill approximately 30 holes all over the sides of the can. Turn the can upside-down, and use the utility knife to cut out the bottom, leaving the curved bottom edge and 1 inch of the can's bottom intact.
2. Set the can in place and fill the bottom 6 inches of the can with loose material such as straw, pruned branches, or spent plants pulled from your garden. Cover with a 2-inch layer of damp, finished compost. Close the can and lock on the lid. You can now begin using the can to collect kitchen trimmings and yard waste, alternating with 1-inch layers of finished compost.
3. To make the base for the rolling bin, build a frame by nailing the 36-inch-long 2 x 4s and the 15-inch-long 2 x 4s together into a rectangular frame. Place the frame on a level surface, and nail the two 18-inch-long 2 x 4s over the top, with their outer edges 12 inches in from the edge of the assembled frame. Mark the centers of each crosspiece, and make four more marks 6 inches from the center marks. Use wood screws to attach the casters to the cross-pieces at each mark.
4. Turn the second can on its side. Hold one of the 1 x 2 furring strips against the outside of the can, and use the drill to make 3 guide holes for the bolts that go through the furring strip and the can. Switch the furring strip to the inside of the can, and install the bolts by threading on washers, inserting the bolts from the outside so they go through the can and the furring strip and extend into the interior of the can. Then screw on and tighten the nuts. Repeat with the 3 remaining furring strips.
5. Use the drill to make approximately 30 aeration holes in the sides and bottom of the second can. Snap on the lid, and place the can on the casters.
6. Whenever the collection can is halfway full, transfer its contents to the rolling can. The easiest way to do this is to lay the collection can on its side, and pull batches of material into the lid with a hoe. Then dump them into the rolling can.

Continued ➔

7. Secure the lid of the rolling can with a bungee cord. Roll the can several times to mix the materials, and add water if needed to lightly dampen the contents. Roll the can every few days. In 3 to 5 weeks, the compost should be ready to use in your garden.

Make an Indoor Worm Farm

Barbara Pleasant

Remember the ant farm you had as a kid? You can have as much fun growing worms, which will reward you with rich fertilizer for your garden. Specifically, the worms create worm castings—excretions high in nitrogen, phosphorus, and potassium, as well as micronutrients and enzymes. Castings are slightly more acidic than garden compost and are a more concentrated source of plant nutrients. You can add them directly to the garden, sprinkle them over the soil's surface of your potted plants, or mix them into potting soil.

Vermicomposting can be done indoors year-round, and it is not stinky when you have the right balance of bedding, water, worms, and food scraps. Bad odors are a sign that you're overfeeding or the bedding is too wet. Fortunately, vermicomposting is easy to do correctly, and it gives you an alternative use for kitchen scraps in winter, when outdoor compost often freezes. It also makes a great science project for kids.

For best results, use red worms (*Eisenia foetida*), which are also known as red wrigglers. They are raised commercially for fishing bait, so you often can buy them by the pint at fishing supply stores. For this project, you will need 1 pound of worms, which is roughly equal to 3 pints of fishing worms. The worms can process about 3 pounds of kitchen waste per week.

This project uses a plastic storage bin, modified to meet the needs of the worms. Keep the bin in a dimly lit place where the temperature stays between 55°F and 77°F. Place it on bricks above a sheet of plastic, and use newspapers to catch any liquids that drain from the bottom. Newspapers enriched with "worm juice" make great garden mulch.

You Will Need

Tools: Drill and ¼-inch drill bit, bucket, pump spray bottle, hand trowel

One 12-inch-deep 50-quart plastic storage bin with lid

Shredded paper for bedding; enough to fill the bin ¾ full

1 quart peat moss

1 cup cornmeal

1 pound of red worms (*Eisenia foetida*)

1. Drill 30 evenly spaced ventilation holes in the bottom and sides of the bin.
2. Place the bedding material and peat moss in the bucket and moisten it uniformly until it is as damp as a wrung-out sponge. Mix in the cornmeal. You may need to prepare the bedding in bucket-size batches.
3. Dump the prepared worm bedding into the plastic bin. Fluff the bedding gently to create air pockets. Mist bits of paper that remain dry.
4. Add the worms to the top of the bedding. Begin adding small amounts of food scraps at first, burying them just beneath the surface. Increase the amount of food as you learn how much your worms can consume.
5. Mist the bedding as needed to keep it slightly damp. Soggy bedding causes odors.
6. After 2 to 3 months, when the worms have converted most of the bedding to castings, use a hand trowel to move the compost and worms to one side of the bin. Add fresh bedding and food scraps to the empty side of the bin. Give the worms a few days to move to the fresh side and then remove the compost. Fill the empty side with fresh bedding.

Make These Nifty Sifters

Barbara Pleasant

Soil sifters separate the big stuff from the little stuff, whether that stuff is the rocks from your garden soil or undecomposed broccoli stalks from your compost. Use different sifters for different jobs; the Rock-Removing Roll is great for sifting out rocks, while the Cheap Seat Sifter will make quick work of turning chunks of compost into fine crumbles.

ROCK-REMOVING ROLL

You Will Need

Tools: Heavy-duty gloves, wire snips, pliers, wheelbarrow

One 6-foot-long piece of 36-inch-wide chicken wire (poultry netting)

6 feet of insulated wire

1. Cut the chicken wire to length, and roll it into a cylinder. Crimp and fold the side edges to close it.
2. Close one end of the cylinder by bending in 12 inches of the chicken wire on all sides. Thread the insulated wire through the side edge seam and through the closed end to keep them closed. Use pliers to wrap the ends of the insulated wire through the mesh to keep them from coming loose.

3. Fill the wire roll with rocky soil, and shake it vigorously to remove soil while retaining rocks. Dump the rocks in the wheelbarrow, and use them for another garden project.

CHEAP SEAT SIFTER

You Will Need

Tools: Utility scissors, staple gun, bucket

One 14-inch-wide cardboard box

One 16-inch square of aluminum window screening

1 old wood chair without seat

Duct tape

1. Remove the flaps from one end of the box, and cut two of them into 1-inch-wide strips.
2. Place the screening over the seat area of the chair, and trim the edges if needed to make them the proper size. Staple the edges in place, sandwiching the cardboard strips between the staples and the screening.
3. Open out the flaps on the other end of the cardboard box, and place it over the screening. Tape the opened flaps to the chair.
4. Place a bucket of compost in the cardboard hopper, and then place the bucket under the Cheap Seat Sifter. Use a hand trowel or gloved hand to stir and scrape the compost across the screen.

Make Straw Bale Beds

Barbara Pleasant

Raise your garden to new heights and get an up-close experience with direct-sown seeds by planting lettuce, bush beans, and trailing flowers in a straw bale bed. You won't have to bend far to tend your plants or contend with weeds, and at the end of the season you can use the decomposing straw as mulch. Get extra mileage from this project by positioning three beds in a semicircle, which creates a protected pocket for hardening off tender seedlings started indoors. If you have a new bed planned for the next season, the bale beds will smother weeds and grasses, so the spot will be ready to dig by fall.

The decomposing straw creates gentle bottom heat, so straw bale beds also are a good way to get a head start on spring. On cold nights, simply cover them with plastic or old blankets, held aloft with sticks stuck into the bales. Bale beds need frequent watering, so keep a hose or watering can handy. In rainy weather, don't be surprised to see mushrooms sprouting from the bottoms of the bales. These "weed" mushrooms are not edible, but their appearance is evidence that naturally occurring fungi are busy promoting decomposition within the bales.

Bale Bed Banquets and Bouquets

You can grow any plants that are not heavy feeders in a straw bale bed. If there is still time left in the growing season, follow lettuce and bush beans with quick crops of fall radishes, turnips, or baby bok choy. If you'd rather grow flowers, stud the middle of the bale beds with upright zinnias, and flank them with cascading petunias. For fall, fill bale beds with bright chrysanthemums, and add a few pumpkins, gourds, or winter squash to complete the display. Keep in mind that wet bales of straw are heavy, so it's best to put them in their permanent places before you plant them. They also become fragile as the straw begins to decompose, so the bales should not be moved until you're ready to tear them apart to use the straw as mulch.

You Will Need

Tools: Scissors, garden hose, handheld digging fork

3 bales of wheat straw

20 yards jute or hemp string

Water-soluble organic all-purpose plant food

Three 20-pound bags of compost

1 packet each bush bean, lettuce, and nasturtium seeds

Continued →

1. Place the straw bales in a sunny spot, with the cut ends of the straw facing up. The bailing twine or wire should be parallel to the ground. To reinforce the baling twine, tie string around the sides of each bale to help hold them together as the straw begins to decompose.
2. Thoroughly dampen the bales, which may require you to water them 3 days in a row. On the third day, drench the moistened bales with plant food, mixed according to label directions.
3. Wait 1 week. Wet down the bales again, wait a few hours for the straw to soften, and then use the small digging fork to chop into the top of the bales. Leave a 2-inch margin of intact straw around the edges. Pry out enough straw to create 6-inch-deep bowls inside each bale.
4. Place half of the compost in the hollowed-out bales, and lightly chop it in with the digging fork to sift it down into the straw. Spread the rest of the compost over the top.
5. Nick the nasturtium seeds with a nail clipper. Soak the nasturtium and bean seeds overnight. Plant the beans 1 inch deep down the center of each bale, and water well. Scatter lettuce seeds down either side of the bean row, and firm them in by patting lightly with the palm of your hand. Poke the nasturtium seeds into the compost 2 inches inside each corner.
6. Keep the compost moist until the seeds germinate, and then thin the seedlings if they are too crowded. Every 2 weeks, give your straw bale beds a thorough drench with liquid plant food.

Grow a Wagon Garden

Barbara Pleasant

That little red wagon that's a little too unsteady for the children or grandchildren is great for moving seedlings indoors and outdoors, so it makes hardening off a breeze. When most of your seedlings are in the ground, use the wagon as a novel container for a compact patio tomato, grown in the company of robust nasturtiums. In the fall, simply clean out the wagon and put it back to work moving plants or other gardening supplies. You can use an old wheelbarrow for this project, too.

You Will Need

Tools: Hammer and nails, tape measure, wood saw, watering can, garden trowel, strips of stretchy cloth

An old child's wagon

One 48-inch-long wood tomato stake

Newspapers

One 20-pound bag of potting mix (more for a large wagon)

1 patio tomato plant

1 packet of nasturtium seeds

All-purpose water-soluble organic plant food

1 stout stick, 2 inches longer than the width of the wagon (optional)

1. Wash and dry the wagon, and use the hammer and a nail to make 10 drainage holes in the bottom of the wagon.
2. To prepare a stake to support the tomato, measure the width of the wagon between the inside edges. Use the saw to cut off the bottom of the tomato stake at exactly this length. Place the long piece of the tomato stake on a flat, solid surface, and center the short piece across the bottom edge to form a T. Nail the two pieces together.
3. Cover the bottom and sides of the wagon with 4 thicknesses of newspaper. Twelve inches from the front of the wagon, install the stake by pushing the base inside the wagon. If it fits very tightly, use the hammer to tap it into place. If the fit is so loose that the stake falls over, shim the ends of the base with squares of folded newspaper.
4. Thoroughly dampen the newspapers before filling the wagon with potting soil. Plant the tomato near the base of the stake, laying its roots and lowest section of the stem at a diagonal angle. Nick the nasturtium seeds with nail clippers before planting them 4 inches apart in the rest of the wagon. Water well, and move the wagon to a place that gets at least 6 hours of full sun each day.

Play It Again

Creative Containers

From old work boots to discarded Easter baskets, perhaps your storage room is a treasure trove of whimsical containers for just the right plants. When using boots or shoes as planters, use a hammer and nail to make a few drainage holes in the soles, and stick with plants that don't mind dry conditions, such as sedums or other succulents. To turn porous baskets into containers, simply line them with a piece of cloth before filling them with soil.

Look for ways to use old pieces of furniture, too. The phrase "garden bed" takes on a whole new meaning when an old bed frame is sunk into the garden and filled with colorful pansies or petunias. And few planters are more charming than an old seatless wooden chair that's been retrofitted to hold a large container of small-fruited cucumbers, or a frothy pot of verbena. Making a sturdy platform for the container is usually a simple matter of cutting two wood slats that can be laid over the chair's rungs.

5. To keep the soil from drying out, cover the soil's surface with damp newspapers until the nasturtium seeds germinate. After the nasturtium seeds sprout and begin to grow, thin them to 4 plants. If desired, lift the extra seedlings and transplant them to your garden.
6. Water your garden as often as needed to keep the soil lightly moist. Topping the soil with mulch will help retain moisture. Every 2 weeks, give the soil a deep drench with a water-soluble organic plant food, mixed according to label directions.
7. As the tomato grows, tie it loosely to the stake with strips of stretchy cloth. When the tomato vine becomes heavy with fruit, reinforce the upright stake by placing a stout stick across the top edges of the wagon, if necessary. Tie it snugly to the stake.

Build a Simple Potting Bench

Vicki Mattern

Planting doesn't happen only in the garden. Most gardeners also plant flowers, veggies, and herbs in pots for the deck or patio or to enjoy year-round as houseplants. This easy-to-build portable bench is perfect for all of your potting, transplanting, and seed-starting work. Because it's made from cedar, it looks good, weathers well, and is naturally rot-resistant. You can set up the bench wherever you need it—it's lightweight and easy to carry. When you're not using the bench, just fold it and hang it on a wall in a shed or the garage.

Materials

1" x 3" x 8' cedar boards (11)
5/16" x 3" carriage bolts (4)
2" galvanized deck screws (40)
¼" galvanized deck screws (12)

1. Cut seven of the 8-foot 1 x 3 boards to the following lengths: eight 48-inch pieces; two 42½-inch pieces; two 20-inch pieces; three 18½-inch pieces; and two 10-inch pieces.
2. Form a 42½-inch x 20-inch rectangle by fastening two of the 18½-inch lengths between both 42½-inch pieces with the 2-inch screws; this is the apron.
3. Use the 2-inch screws to fasten the third 18½-inch piece between the sides in the center of the rectangle; this is the center batten.
4. Fasten the two 20-inch pieces across the ends of the rectangle, using the 2-inch screws at the ends and the 1¼-inch screws in the middle.
5. Fasten the 10-inch pieces in opposite corners of the rectangle, using the 1¼-inch screws; these are the spacers that allow the legs to fold properly.
6. Fasten the eight 48-inch pieces to the top of the apron, using 2-inch screws, to complete the tabletop.
7. Turn the tabletop over and attach the 18½-inch center batten to it with 1¼-inch screws.
8. To make the legs, cut two 8-foot 1 x 3 boards into four pieces, 29½-inches long and tapering from 3 inches at one end to 1½ inches at the other. Round off the wide end and drill a 5/16-inch diameter hole through the center point at that end.
9. Drill four 5/16-inch diameter holes through the apron and spacers, then bolt the legs to the tabletop.
10. For leg braces, cut the remaining 8-foot boards into two 20-inch and two 17⅝-inch pieces. With the legs open slightly past 90 degrees, use 2-inch screws to attach the 20-inch braces to them so that the braces act as stops against the apron.
11. Fold the legs up against the table and attach a 17⅝-inch brace across each pair of legs at the point where they just clear the opposite legs when folded; use 2-inch screws.

Build a Raised-Bed Hoop House

Vicki Mattern

Materials

Frame: Untreated 6" x 6" landscape timbers (two 8' pieces and two 4' pieces)

Hoops: ¾" diameter flexible conduit (four 10-inch pieces)

Ridgepole: One 8' 2 x 2 stud

Cover: One 10 x 25' roll of 6-mil greenhouse-grade plastic (cut four 52"-square pieces and one 8½ x 12½" piece)

Side anchors: Two 8' 2 x 2 studs

Also: Small wooden stakes, staples, sheet metal screws, cardboard

A hoop house is an inexpensive, portable structure for extending the growing season. For extra frost protection, you can cover it with an agricultural foam "blanket" on cold nights. Here's how to build a simple 4-foot-high hoop house:

Continued ➔

1. Build a raised-bed frame (about 4 feet wide x 8 feet long) using untreated landscape timbers. Drill four equidistant 1-inch-diameter holes into the tops of both long sides, drilling all the way through the wood. These holes will anchor the hoops.
2. Create a template for the hoops by driving wooden stakes into the ground, forming a 4½-foot-high arch. The two bottom stakes should be about 4 feet apart, with the curved section beginning about 21 inches from the bottom of each side. Arch and form the hoops using the ¼-inch-diameter metal conduit sold to protect electrical wires. Gently bend the conduit around the stakes.
3. To raise the roof, drill four equidistant 1-inch-diameter holes in the ridgepole to match the four pairs of holes in the frame. Run each hoop through a hole in the pole, securing it by running a sheet metal screw down through the pole and into the hoop. Insert the hoops into the frame.
4. Trim the plastic squares to be about 1 inch bigger all around than the area of the end hoops. At each end, put one piece on the inside of the hoop and one on the outside, then staple the edges together all around the hoop.

   Center the large piece of plastic over the ridgepole, then staple it to the pole. (To keep the plastic from tearing, cut thin cardboard into long strips and place these over the plastic before stapling.)

   On each side, anchor the plastic by stapling the bottom to the two remaining pieces of lumber. When ventilation is needed on warm days, simply roll up the sides.

Greenhouse Seed Starting

To start seeds in a cool, unheated greenhouse, use a germination mat—a rubber heating pad that provides consistent (and in some models, adjustable) bottom heat. Stack your seed-starting flats so that heat-loving seeds, such as hot peppers, are on the bottom, closest to the heat. Put cool-loving germinators, such as lettuce, above them, where temperatures will be 5° to 10°F cooler.

Or, simply germinate the seeds in your house, where it's already about 70°F. After the seeds sprout, transfer the flats to the greenhouse, where the light is brighter.

Get a Greenhouse

Vicki Mattern

Want to extend your growing season to include all four seasons? Buy or build a greenhouse. Many sizes and styles are available, ranging from simple, unheated structures that you fit on a porch or patio to freestanding, climate-controlled conservatories. No matter what type of greenhouse you use, paying attention to these factors will maximize your chance of success:

1. Get the light right.
The quantity and quality of the light that enters a greenhouse from the outside can vary tremendously depending on the type of see-through material—known as *glazing*—that is used for the ceiling and walls. Corrugated polyvinyl chloride (PVC), for example, lets in 84 percent of the available light, while Plexiglas lets in 93 percent. That may not seem like a big difference, but it is to your plants!

As a rule of thumb, every 1 percent increase in light transmission of your glazing material increases plant growth 1 percent during winter. So, that 9-percent difference between PVC and Plexiglas could well prove to be the difference between success and failure—especially if your greenhouse will be located in an area with a lot of winter cloud cover. There, greenhouse owners need to make the most of every bit of sun they get.

Cleanliness counts, too. If your greenhouse covering is dirty or dusty, wash it. Then establish a regular schedule of window washing.

If your greenhouse is covered with a flexible plastic film that has yellowed, replace it with a greenhouse-grade plastic designed to take the sun (available from greenhouse supply companies). The newer greenhouse plastics contain ultraviolet inhibitors that can extend the life of the plastic 4 years; infrared inhibitors, which reduce heat loss at night; and wetting agents so that condensation runs down the sides of the greenhouse instead of dripping onto your plants.

How you arrange plants inside the greenhouse can make a difference too. The area of brightest light is next to the glazing. At the end walls, where the framing interferes with light transmission, the lower light levels are better for shade-loving plants like impatiens.

2. Keep it hot, hot, hot.
Greenhouses are like growing zones. They contain micro climates of cold and hot spots. If you learn where these areas are, you can satisfy the needs of both heat lovers (such as tomatoes, peppers, eggplants, and cucumbers) and cool-clime plants (such as lettuce)—all in the same greenhouse.

Place several thermometers throughout your greenhouse to learn the best place for growing specific plants. Shade-tolerant azaleas, for instance, may do best under the bench, where the temperature is a bit cooler and the light is indirect. Tropical

orchids and bougainvillea are likely to thrive near the ceiling, where it's hotter and brighter.

Just be aware that the warmest spot by day—next to the glazing—becomes the coldest spot at night. You can stabilize indoor temperatures by incorporating heat-storing masses, such as brick floors and water barrels, in your greenhouse's design.

You may also want to add some supplemental heat to your greenhouse. If the greenhouse is attached to your home, you can tie it into your home heating system. If you choose to use a natural gas or propane heater, be sure to spend the extra money to vent the heater outside. Both of these gases produce sulfur dioxide and ethylene gas, which can harm plants. The sulfur dioxide, for instance, combines with the water that condenses on the inside of glazing to form sulfuric acid (acid rain!). Be careful, though, that you don't melt the glazing with the heater's surface.

3. Keep the air moving.
Warming a greenhouse is important, but keeping it cool can be crucial! In many parts of the country, too much heat is the biggest problem greenhouse growers must prepare for. As the sun beats down on your greenhouse during the unpredictable weather of spring, the air trapped inside can quickly heat up to 110°F or more. Ceiling vents that let hot air escape from the top of the greenhouse are the best protection, particularly in hot or sunny climates. Second best are vents and fans located on the end walls to bring in cool air from outside.

If you aren't around during the day to control the ventilation yourself, spend a bit more to get automatic vents. Most are gas-filled cylinders that push the vent open as rising heat expands the gas inside. You also can get thermostatically controlled exhaust fans that run when the mercury reaches a preset temperature.

Air circulation is important even when you aren't venting excess heat. Having a fan running continuously inside a sealed greenhouse, for instance, is nearly a necessity. It can lessen the chance of plant diseases taking hold and help prevent depletion of the carbon dioxide (CO_2) that plants need for photosynthesis.

Individual plants tend to totally deplete the CO_2 in a tiny envelope of air that surrounds each leaf. But the CO_2 in these tiny pockets can be replenished somewhat by simply moving the air around with a fan. To completely replenish the CO_2, you'll need to open a vent to bring in fresh air.

4. Gauge the humidity.
Buy a humidity gauge (you can find them in hardware or home supply stores) so that you can maintain a relative humidity level of 40 to 50 percent inside your greenhouse. Most times, this means adding a little moisture to the dry winter air. In that case, either run a humidifier or try venting your electric clothes dryer into the greenhouse.

But you could need to *lower* the humidity, instead. If you overwater (especially in winter), the excess will go right into the air, raising the humidity level to as high as 95 percent. And high humidity coupled with poor air circulation can set off an explosion of root rot or powdery mildew on your plants.

To prevent such problems, water only when the soil in your greenhouse containers is dry—and watch that humidity gauge. You can also run an exhaust fan or just open a window on a warm winter day to decrease the humidity.

Stoop-Free Potting Bench

Roger Yepsen

You can make this potting bench in about a weekend, if you have basic woodworking skills. If not, show the drawings and general construction steps to a carpenter or woodworker and have them do the job. This design includes a few optional features: a tool shelf below the work surface, and a seed packet shelf and herb-drying bar above. The bench is made from 5/4 pine, which typically measures just over 1 inch thick. You can paint, stain, or varnish the piece, or leave it unfinished.

A standard height for a work surface is 36 inches, but that may not be right for you. If your kitchen counters are comfortable to work at, measure their height and use this dimension for the bench. Overall, the bench measures 72 inches high, 48 inches wide, and 28 inches deep.

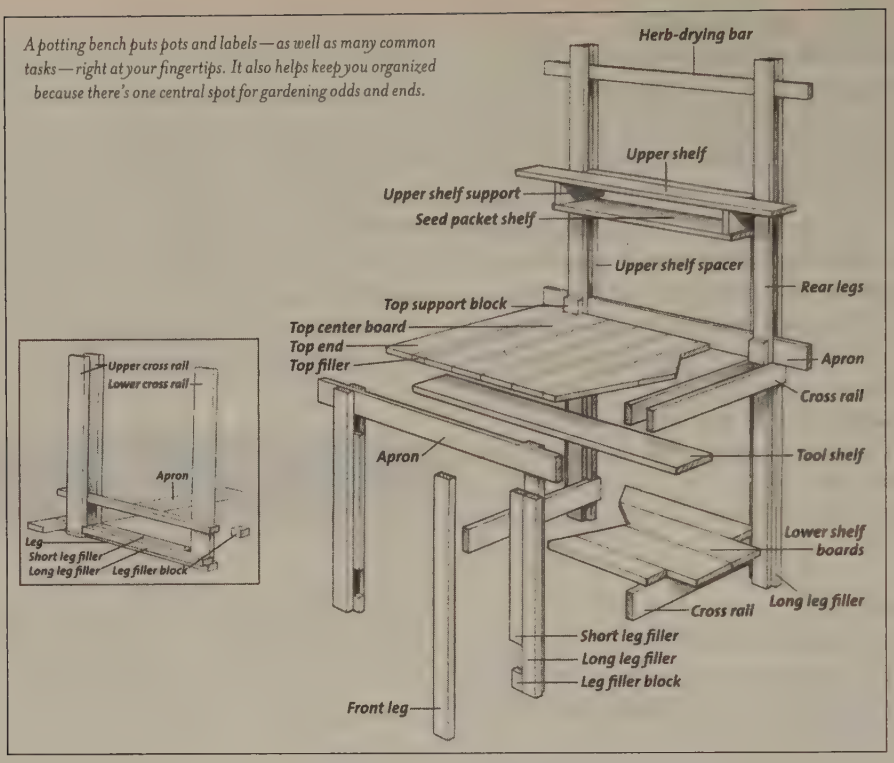
The bench is put together with both screws and water-resistant polyvinyl acetate glue (such as Titebond II). Parts are assembled with glue on their mating surfaces, then clamped before driving the screws.

What You'll Need

96 feet 5/4 x 6 pine
#6 x 2-inch galvanized screws
#8 x 3-inch galvanized screws
2½-inch galvanized finishing nails

1. The legs are "sandwiches" of several pieces, which allows you to make sturdy joints without the need for tricky cuts. Assemble them as shown in the detail view, together with the apron and cross rails.
2. Construct the rear legs, attaching them to the cross rails and then slipping in the rear apron.
3. Nail the boards for the lower shelf, with a little space between them to allow the wood to expand and contract. Attach the

Continued ➔



A potting bench puts pots and labels—as well as many common tasks—right at your fingertips. It also helps keep you organized because there's one central spot for gardening odds and ends.

narrow tool shelf to the underside of the cross rails with screws.

4. Make the tabletop, with the boards running front to back rather than the usual lengthwise configuration. This allows you to make use of short scrap pieces and also will make it easier to brush off the surface. Attach the small support blocks to the rear legs, then nail the narrow fillers. Next come the end boards, and finally the boards in the middle. Nail the boards into the aprons.

5. Assemble the upper shelves, fitting the upper shelf spacers into the slot between the rear legs. Attach the upper shelf supports to the rear legs with screws. Trim the back of the upper shelf to fit between the rear legs, then nail it in place. Nail the upper shelf front onto the supports. Also nail the seed packet shelf onto the bottom of the shelf supports, and the herb-drying bar between the rear legs.

Fashion Your Own Fence

Roger Yepsen

You can buy all sorts of fencing material at a home and garden center, including preassembled panels in various woods or plastic. To set your garden apart, give some thought to designing your own pickets. The least expensive option is to saw them to length from bundles of 1 x 3s. You can even cut decorative top ends on each picket—a time-consuming project, but one that will set your garden apart. A few ideas are shown here. Make straight cuts with a circular saw or saber saw; a saber saw will negotiate any curves; and a drill will make the holes. To drill the half-circle cutouts in adjacent pieces, place them side to side in a simple jig that, along with a couple of clamps, will hold them securely. A *forstner* bit in an electric drill will make a neater bore. If you put a sharp point on the pickets, the fence will be that much more formidable to climbing and leaping animals.

Make a Planting Bar

Barbara Pleasant

When you're planting lots of garlic or onions, or dropping large seeds into the ground, a planting bar can save time and help you get spacing perfect. When you're not using the planting bar for planting, hang it from a wall and use it to hold bunches of herbs or flowers as they dry.

You Will Need

Tools: Measuring tape, handsaw, pencil, drill with ½-inch bit, hammer

One ½-inch-diameter wooden dowel

One 36-inch-long piece of 2 x 4 lumber

Five 2-inch-long finishing nails

Creative Fence Posts

As you plan a garden fence, consider having at least a couple of posts extend higher than usual. These extra-tall posts can do double duty, providing a place to hang a birdhouse where you can enjoy the occupants (as they help you control plant-eating worms). Shy birds might not take to such a public spot, but wrens seem to put up with having humans nearby, even though they show their irritation by chattering a good deal. Or, string wire between a pair of tall posts for training sweet peas, runner beans, or honeysuckle.

1. Use the saw to cut five 3-inch pieces from the dowel.
2. Mark 6-inch increments down the middle of the broad side of the 2 x 4.
3. Drill holes through the board at each mark. Insert a piece of dowel into each hole.
4. Place the assembled planting bar on a solid surface, narrow edge down. Nail through the edge of the bar and into each dowel piece to secure them in place.
5. To use the bar, place it on prepared soil and jiggle it back and forth to make 5 perfectly spaced planting holes. When planting a broad bed, pick up the planting bar and, with the end dowel still in the first planting hole, pivot the bar to make a perpendicular set of holes. Then make a row at each end hole, and so on down the row.

Make a Handy Sink Screen

Barbara Pleasant

On busy gardening days when you're constantly washing out pots or grooming plants, you will spend less time cleaning up after yourself with the help of a sink screen. Keep your sink screen in a cabinet between uses, or let it do double duty as a drying rack for kitchen herbs. This 12 x 12-inch version fits perfectly into a standard-size kitchen sink.

You Will Need

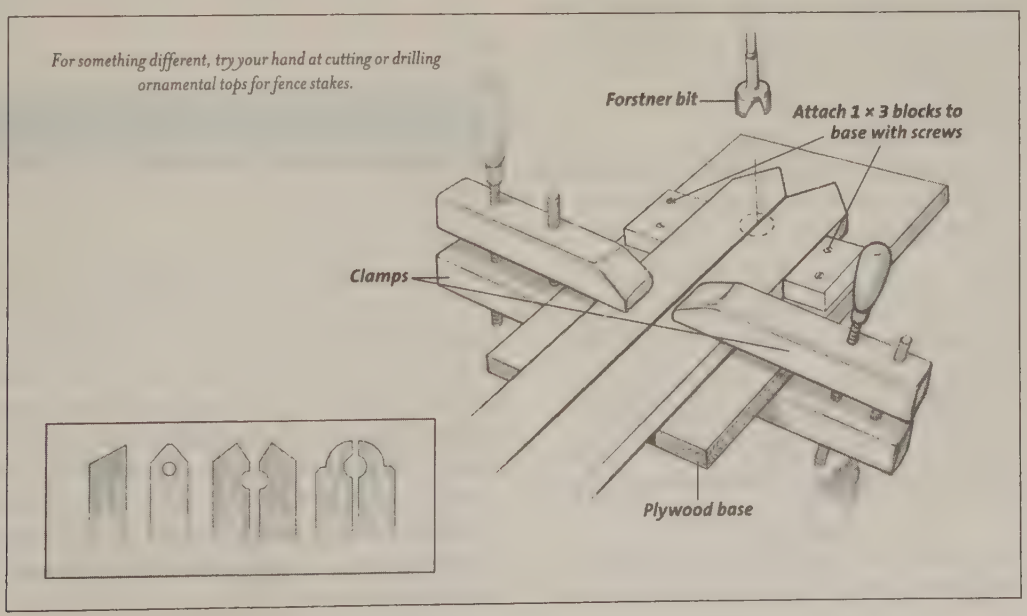
Tools: Tape measure, handsaw, hammer, scissors, staple gun

One 6-foot-long 1 x 2 furring strip

Sixteen 1½-inch nails

1 small roll of polyester window screening

1. Cut the furring strip into six 12-inch-long pieces. Place two of the cut pieces on a flat surface, broad side down, and partially drive 2 nails into each end, ½ inch from the outer edge. Position two pieces at right angles to the first two, overlapping the corners, and nail them together to form a box.
2. Cut a piece of screening 12 inches wide and 12 inches long. Staple it to the frame.
3. Place the remaining two pieces of 1 x 2 along the high sides of the frame, flat side down, so they cover the edge of the screening. Nail them in place.



For something different, try your hand at cutting or drilling ornamental tops for fence stakes.
Forstner bit
Attach 1 × 3 blocks to base with screws
Clamps
Plywood base

Build a Propagation Bed

Barbara Pleasant

The more you garden, the more you need a holding bed for plants you're not quite ready to plant, as well as those that need some growing time before they are set out in the garden. As temporary quarters for perennials you've divided, or plants given to you by a generous friend, a quickly constructed propagation bed is hard to beat. Locate it in a spot that gets afternoon shade, so plants with skimpy roots won't have to struggle against the demands of hot sun. Reinforced by a sturdy plywood bottom, this bed can be moved if needed to give plants exactly the exposure they prefer. When the bed is left situated in one place, the bottom serves as a barrier to tree roots and soil-dwelling insects, and keeps the propagated plants from settling in too deeply as well.

This bed measures 2 x 4 feet, which is the same size as a quarter sheet of plywood. Most home supply stores carry precut pieces, so the only sawing required is cutting the frame pieces, which can be done with a handsaw. The light, loose texture of the sand–peat moss mixture promotes fast root development, discourages soil-borne diseases, and makes it easy to lift plants when their new homes are ready. You also can sink container–grown plants into the propagation bed to help keep their roots cool and moist.

You Will Need

Tools: Tape measure, pencil, handsaw, hammer, drill with ¼-inch bit, garden spade, wheelbarrow, garden hose

12 feet of 1 x 8 pine or cedar lumber

Thirty-four 2-inch nails

One 2 x 4-foot piece of ¼-inch plywood

One 6-foot-long 1 x 2 furring strip

One 50-pound bag of play sand (1 cubic foot)

One small bale of peat moss (1 cubic foot)

1. To make the frame, measure and cut the 1 x 8 boards into two 4-foot-long pieces and two 2-foot-long pieces. Nail them together at the corners to form a box.
2. Place the plywood over the assembled frame, and nail it in place. Use at least two nails for each short side, three nails for each long side, and one nail at each corner.
3. Cut the furring strip into three 2-foot-long pieces. Nail one to each end of the frame, broad sides down, sandwiching the plywood between the furring strip and the frame. Nail the remaining piece across the center of the frame.
4. Use the drill to make 12 evenly spaced drainage holes in the plywood. Move the bed to its permanent location.
5. Use the spade to thoroughly mix the sand and peat moss together in a wheelbarrow. Dump the mixture into the assembled bed, and drench with water. Wait a few minutes for the peat to absorb the water, stir the mixture, and water it again. Repeat if necessary until the peat particles appear dark with moisture.
6. To use the bed, simply sink plants into the sand–peat moss mixture and keep them moist until you are ready to lift them out and plant them in your garden.
7. To move your bed, remove some of the sand–peat moss mixture, and allow the rest to dry out. Get a helper to help you move the dry, partially filled bed.

Make a Double Pot Propagator

Barbara Pleasant

This easy system, which makes use of the porous nature of inexpensive terra-cotta clay pots, sets up in a snap and always gives good results. Water poured into a sealed small pot is slowly absorbed by the rooting medium, and a plastic tent provides the humidity needed by rootless cuttings. A half-and-half mixture of sand and peat moss makes a good medium for rooting cuttings, or you can use damp seed-starting mix or perlite. Regardless of which medium you choose, start over with a fresh batch for each new crop of cuttings. Develop your propagation skills with fast-rooting cuttings such as chrysanthemums, or coleus, before moving on to woody plants, which need more time to develop new roots.

You Will Need

Tools: Bucket, hand trowel, measuring cup, pump spray bottle

One 8-inch-wide clay flowerpot

One 4-inch-wide clay flowerpot

One 6-inch clay pot saucer

1 quart clean sand (such as play sand)

1 quart pulverized peat moss

Two 1-inch-square pieces of duct tape

1 cup small, clean pebbles

4 chopsticks or wood skewers

8 to 10 prepared stem tip cuttings

1 opaque plastic produce bag

1. Thoroughly clean the pots and pot saucer. If you are using new ones, place them in a tub of clean water to soak for 10 minutes, and then allow them to drip dry.
2. Place the sand and peat moss in a bucket, and use a hand trowel to mix them together. Add 2 cups of lukewarm water, mix, and then add another 2 cups of water. Mix again, and allow the mixture to sit for 10 minutes. If pieces of the peat moss still appear dry, add more water until the mixture is the consistency of raw cookie dough.
3. Cover the drainage hole in the bottom of the 4-inch pot with the pieces of duct tape. Place one on the inside of the pot, and the other on the outside.
4. Place the pebbles in the bottom of the 8-inch pot. Add a 2-inch layer of the sand/peat moss mixture. Set the 4-inch pot in the center, and press lightly. Add more of the sand/peat moss mixture if needed to raise the top rim of the smaller pot ½-inch above the top rim of the larger pot.
5. Fill the space between the two pots with the sand/peat moss mixture. Spray lightly with water, and add more sand/peat moss mixture if needed until the space is filled to within ½-inch of the top of the 8-inch pot. Gently lift and rinse out the smaller pot, and then put it back into place.
6. Use one of the chopsticks or skewers to make 8 to 10 evenly spaced holes in the sand/peat moss mixture for cuttings. Stick the prepared cuttings into the holes, and use your fingers to make sure they are in firm contact with the rooting medium.
7. Insert the chopsticks or skewers along the outside of the 4-inch pot. Place the Double Pot Propagator on the saucer, and position it in a warm place out of direct sunlight. Pour 1 cup of lukewarm water into the small pot, and then cover the Propagator with the plastic bag, arranging the folds so the plastic is held above the cuttings by the chopsticks or skewers.
8. After 2 days, remove the plastic bag and use your finger to see if the sand/peat moss mixture is still moist. If it feels dry, add ½ cup water to the small pot. Replace the plastic cover.
9. Check the moisture level again every other day, and add ½ cup water to the small pot whenever it becomes empty. Remove any cuttings that have wilted. Leave the plastic cover off at night, but put it on during the day.
10. Three weeks after setting the cuttings to root, pull gently on cuttings that show evidence of new growth. If you feel slight resistance, use a fork to lift them and transplant them to small individual pots. Keep the transplanted cuttings in a shady place outdoors, or indirect light indoors, and keep moist. Increase light as new growth appears.

Make a Portable Trellis

Barbara Pleasant

As handy as a pocketknife, a portable trellis made with chicken wire attached to 1 x 2s can work as a freestanding support in an open vegetable or flower garden, or you can place it next to a wall or wood privacy fence. You can change its shape, too, so the same trellis that supports a straight row of peas in spring can be changed into a circular cage for summer tomatoes. When winter arrives, simply pick off the dead vines and roll up the trellis like a scroll for storage, or use it as a collection bin for leaves. Best of all, this trellis comes together so quickly that you can make several in one afternoon.

Farm supply stores often stock chicken wire (also called poultry netting) in 36-inch or wider widths, but most home supply stores sell the 24-inch-wide version. Plain galvanized wire is fine, but many gardeners prefer chicken wire that has been covered with a vinyl coating because it looks better and is easier to clean at the end of the season. Both types are inexpensive to buy, and you will find plenty of uses for small leftover pieces. A 12-inch square piece, crumpled into a ball and placed in a teapot, is a flower arranger's best friend.

You Will Need

Tools: Thick gloves, tin snips, staple gun, hammer, spade, scissors, carpenter's level

10-foot roll of 24-inch-wide 20-gauge chicken wire (poultry netting)

Four 5-foot-long pieces of 1 x 2 cedar lumber

Eight 1½-inch galvanized finishing nails

Cord, twine, or wire for use as guy wires

Four 18-inch-long wood stakes

1. Wearing gloves, use the tin snips to cut two pieces of chicken wire 4 feet long.

Continued ➔

2. Set two of the 1 x 2s on a flat surface, 4 feet apart, with their broad sides down. Use the staple gun to attach the chicken wire to both 1 x 2s, beginning at the top edge and allowing a ½-inch margin between the outer edge of each 1 x 2 and the chicken wire. Attach a second piece of chicken wire below the first one.

3. Top each 1 x 2 with another, sandwiching the edges of the chicken wire between them. Nail them together with the finishing nails.

4. Dig two 12-inch-deep holes for the trellis legs. Set the trellis in place, and refill the holes. Firm in the soil around one leg, and stabilize it with two guy wires attached to two stakes. Use the level to make sure the trellis stands up perfectly straight.

5. Adjust the position of the second leg, stretching the trellis tight as you work, before installing the last two stakes and guy wires. Check to make sure the trellis is straight before firming the soil around both legs.

A Trellis That Suits to a "T"

Barbara Pleasant

The T-bar trellis offers grapes and other fruiting vines what they need for better health and higher yields—maximum exposure to light and a permanent place to ramble. You can use it for hardy kiwis or long-handled dipper gourds, too, or make a shorter version for raspberries. Consisting of two T-shaped posts set 12 feet apart and connected with three runs of galvanized wire, this trellis is meant to last for many years, so the posts are permanently set in concrete. This is a heavy trellis that requires the joint efforts of two people to build and install.

If you dream of a shady sitting place near a too-sunny garden, you can use two T-posts to support a small pergola. Set the posts 6 feet apart and top them with wood slats or a panel of cedar or redwood lattice, nailed into place.

T-trellises do not have to work in pairs. To use a single T-trellis to support a vigorous climbing rose, install diagonal wires between the ends of the crosspieces and the base of the post, and tie new canes to these wires with strips of soft, stretchy cloth. A single T-trellis also makes a great structure for supporting a collection of hanging baskets, which can be hung from the crosspieces as well as the main post.

You Will Need

Tools: Measuring tape, power saw, drill with ¼ -inch extension bit, ratchet wrench, posthole digger, level, wheelbarrow, spade, wire snips

One 6-foot-long 4 x 4

Two 8-foot-long 4 x 6 posts of rot-resistant wood (cedar or locust)

Two 5-foot-long 4 x 6 crosspieces

Four 10-inch-long ⅜-inch-diameter lag screws

20 flat metal washers

Eight 5-inch-long ⅜-inch-diameter lag screws

Eight 7-inch-long ⅜-inch-diameter lag screws

6 large screw eyes

2 bags premixed concrete

42 feet of galvanized, high-tensile, 12-gauge wire

Three 5½-inch turnbuckles

1. To make the braces, measure and saw four 16-inch pieces from the 6-foot 4 x 4. Then cut 45-degree angles at the ends of each piece.

2. Lay the two 4 x 6 posts on a flat surface, broad sides down. Place 5-foot-long crosspieces at the tops of each post, measuring to make sure they are perfectly centered. Drill guide holes for two 10-inch lag screws 2 inches apart on the tops of the crosspieces. Thread washers onto the 10-inch lag screws. Use the ratchet wrench to attach the crosspieces to the posts with lag screws.

3. To attach braces to each T-post, position the braces and drill guide holes at each junction for one 5-inch and one 7-inch lag screw. Install the screws with washers as you did in Step 2, placing them at horizontal and vertical angles.

4. Mark the center of each crosspiece. Then mark spots 4 inches inside each outside edge. Drill guide holes for the screw eyes, and securely screw them into place.

Get Creative with Cloches

The historical version of a garden cloche was a glass bell jar, but in more recent times, resourceful gardeners turned to cloches made from plastic milk jugs with their bottoms removed. To help hold a milk carton cloche steady in the wind, push a stick through a V-shaped cut made in the top of the handle. Leaving the top off of a milk jug cloche creates an instant vent.

To cloche a plant that's too big for a milk carton, use bubble wrap to make an insulated teepee. Place four or more 24-inch-long sticks around a plant, tie them together at the top, and enclose the base of the teepee with a 16-inch-wide band of bubble wrap (available in the office supply section at discount stores). Secure the wrapping in place with clothespins, and be sure to leave an opening at the top through which hot air can escape.

5. Dig 24-inch-deep postholes 12 feet apart. Set each assembled T-section in the holes, and use a level to make sure they are plumb. Mix concrete according to label directions, and shovel it into the holes. Allow the concrete to set for at least 48 hours.

6. Cut three 14-foot lengths of the 12-gauge wire. Screw a turnbuckle to its maximum length, and hook one end into a screw eye. Thread the end of a piece of wire into the other end of the turnbuckle, loop the end through the eye twice, and then loop it around itself. Attach the other end of the wire to the opposite T-post, stretching the wire as tightly as you can. Twist the turnbuckle to further tighten the wire. Cut off the excess wire, leaving a 3-inch-long tail.

7. Repeat Step 6 to install the remaining 2 wires.

Make a Tube Hoop Cloche

Barbara Pleasant

If you want to get a head start growing widely spaced hills of potatoes, squash, or melons, or protect a drift of flowers from late freezes, you need a cloche that can cover some ground. A Tube Hoop Cloche covers a 20-inch-diameter circle, and it's easy to move from place to place. Made from easily scavenged materials, this cloche looks like a giant shower cap. An opening in the top makes it easy to vent on sunny days, or you can close it up tight when the weather turns cold. When the vent is open, a coat hanger attached to the stake keeps the plastic from falling down onto the plants below.

You Will Need

Tools: Heavy-duty scissors, measuring tape, utility knife, office stapler, felt-tip marker, pliers

1 bicycle inner tube

One 7-foot-long piece of old garden hose

One 4-foot-square piece of 4- or 6-mil clear plastic

1 wire coat hanger

One 20-inch-long piece of ½-inch PVC pipe

2 thick rubber bands

1. Use the scissors to remove the air valve from the inner tube by cutting across the tube on either side of the valve. Use the utility knife to trim the garden hose to 2 inches shorter than the length of the tube, or about 70 inches.

2. Slip the hose inside the tube. Overlap the ends of the tube about ½ inch. Pinch together the overlapped edges of the tube on the outside of the hoop, and staple them together.

3. Spread out the plastic, and lay the prepared tube on top. Use the scissors to cut a circle of plastic 12 inches wider than the hoop on all sides (about 46 inches in diameter). Make 8 equally spaced marks along the outside edge of the plastic circle with a felt-tip marker.

4. Pull the loose plastic up through the center of the hoop, and staple the edge of the plastic to the outside of the hoop at equal intervals by pinching the inner tube, folding the edge of the plastic over the pinched rubber, and stapling it in place. Using the marks on the plastic as guides, begin by stapling 4 opposite points around the edge of the tube. Then install staples at midpoints between the first 4 staples. Between the 8 stapled points, gather the loose edges of plastic into pleats. Fold the pleats over and staple them to the tube.

5. Use the pliers to bend down the hook of the coat hanger. Hang the coat hanger in the top of the stake, and secure it in place with a rubber band. Push the PVC pipe stake into the ground near the plant you want to protect, and center the Tube Hoop Cloche over the stake.

6. Use scissors to cut a 6-inch-wide X in the top of the plastic. Hold the cut edges together above the top of the stake and secure them with a rubber band. On sunny days, remove the rubber band so hot air can vent out of the top of the cloche. When open, the top edges of the plastic will be supported by the clothes hanger.

7. To move the cloche, secure the top edges of the plastic to the top of the pipe with a rubber band, grasp the pipe firmly just above the coat hanger, and pull it up. Place the cloche in its new place, and push the pipe into the ground.

Build an Isolation Box

Barbara Pleasant

If you want to protect an individual plant from insect or animal pests, a simple frame that can be covered with rowcover or another lightweight fabric will do the trick. This is a great way to keep Japanese beetles away from a treasured rose during their 6-week feeding period, or to safeguard a tomato from the moths whose larvae become tomato hornworms. An isolation box can serve other purposes as well:

- If you plan to save seeds from a certain plant, you can use your isolation box to exclude pollinating insects (unless the plant is self-fertile, you will need to distribute pollen between different flowers by hand).
- When you decide that you must use an organic pesticide, you can use the box to exclude beneficial insects for a day or two after the plant is sprayed.
- Use the frame to support bird netting if berries or tomatoes need temporary protection.
- Cover the frame with an old sheet to turn the box into a shade cover for seedlings set out in hot weather or for

Continued ➔

newly seeded beds of slow sprouters such as carrots, parsley, or onions.

This lightweight model goes together in minutes, and because the joints are not glued together, it can be taken apart and stored when not in use. Simply pop the pieces apart, hose them down, and bind them together with string or a large rubber band. Don't hesitate to alter the size of the frame to fit your needs. To raise the frame's height, simply attach additional pieces of PVC pipe to the legs.

You Will Need

Tools: Measuring tape, handsaw, pruning shears or loppers

Two 10-foot pieces of ½-inch PVC pipe

Four ½-inch-diameter 3-way (90 degree) elbow connectors

Four ½-inch-diameter male connectors

Four 18-inch-long straight sticks or bamboo stakes

One 10-foot-square piece of rowcover

1. Saw the pipe into four 30-inch-long pieces—four for the top of the frame and four for the legs.
2. Arrange four of the cut pieces into a square on a flat surface. Firmly push the ends into the elbow connectors to form a box. With the open ends of the connectors facing up, screw in the male connectors until tight. They may not screw in all the way. Firmly twist the legs into the open end of the connectors.
3. Carry the frame to where you want to use it, and adjust the position of the legs to make the frame square. Mark the places where the legs touch the ground.
4. Use the pruning shears to trim sticks or stakes. Push the sticks or stakes into the ground 10 inches deep at the places marked for the legs, making sure they are perfectly straight. Lift the frame, and slip the legs over the sticks. Push the legs into the soil 3 inches deep.
5. Cover the frame with rowcover, and secure the bottom edges with bricks, stones, or pieces of scrap lumber.

Rowcover Alternatives

Rowcover fabric made for home gardens doesn't have holes in it, so it blocks only a little light, and tiny flea beetles can't get through to damage plants. There are other fabrics that make good stand-ins for purchased rowcover fabric, such as flexible polyester window screening, discarded sheer draperies, or mosquito netting. Another great option is tulle, the polyester net fabric used to decorate ballet tutus, bridal veils, and party tables. Inexpensive and widely available at fabric and craft shops, tulle even comes in festive colors. The openings in the net are less than 1/16-inch wide, so tulle is best used as a barrier for medium to large-size insects, such as various beetles and moths.

Tulle is usually 59 inches wide, which is not wide enough to completely cover a tunnel or box. When using any alternative material that's too narrow to give good coverage, simply sew pieces together with a needle and thread, or use a sewing machine. Rowcover can be cut and sewn, too. If you know how to sew, try creating unique garden fashions from rowcover or alternative fabrics, such as a quick slipcover, for the Isolation Box.

Fashion a Flashy Scarecrow

Barbara Pleasant

Most gardeners enjoy the sight and sound of birds in the landscape—until those feathered friends take a liking to newly planted seeds, tender seedlings, and just-ripened berries. Songbirds are most likely to visit the garden in search of caterpillars and other tasty bugs, but crows, mockingbirds, jays, and a few other species sometimes become "beaks gone bad." Before these clever creatures learn that your garden is a great place for lunch, put a scarecrow or two on patrol.

Anyone who's ever done battle with crows or jays knows that the term "bird-brained" is less of an insult than most people think. These birds are bold and intelligent, and they quickly recognize the difference between genuine threats and our feeble attempts to chase them off. You can make a traditional scarecrow stuffed with straw, but this flashier version is more likely to do a good job of spooking birds. Birds quickly become accustomed to stationary stuffed scarecrows and will eventually use them as perches. They are much less likely to cozy up to a scarecrow that flashes in the sun, flaps in the wind, and has brightly colored dangling hands. A successful scarecrow may not win a prize in the fall porch-decorating contest, but its features will make it scarier to birds than any benign straw-stuffed dummy.

You Will Need

Tools: Wood saw, scissors or wirecutters, pliers, stepladder, rubber mallet

1 sturdy bamboo pole or tall fence post

3 yards of string or thin, pliable wire

1 metallic compact disc (or aluminum pie pan)

1 wire clothes hanger

Two 18-inch-long wood stakes

8 wood or plastic clothespins

1 suit of old clothes, including a long-sleeved shirt and pair of baggy pants or billowy skirt

1 pair of brightly colored rubber gloves

1. Use the saw to cut a shallow 1-inch-deep V-shaped notch in the top of the bamboo pole or fence post. Use string or thin wire to hang a shiny compact disc or a pie pan from the top of the pole, running the string through the notch to keep it from slipping. This forms the scarecrow's "head." If desired, use a waterproof marker to draw eyes on the scarecrow's face.
2. Attach a second piece of string or wire to the top of the pole, and pull a loop through the center hole of the disk (or through a hole punched near the lowest rim of the pie pan). Hook the clothes hanger through the loop. Use pliers to close the hanger's hook to help keep it on the loop.
3. Use the rubber mallet to drive the prepared pole in place in your garden. Pound 2 stakes into the ground on either side of the pole, and secure it with guy wires tied or wired to the stakes.
4. Use clothespins to fasten the pants or skirt to the hanger's cross bar. Slip the shirt over the hanger. Don't worry about stuffing the clothes—it's better if the scarecrow's "body" flaps in the slightest breeze.
5. Fasten the rubber gloves to the ends of the sleeves with clothespins. If the weight of the gloves makes the sleeves too heavy to move freely, slip a long branch, a straight piece of wire, or a yardstick into the sleeves to hold them out from the scarecrow's "body."
6. Let your scarecrow blow in the breezes. If necessary for stability, use string or fine wire to loosely attach the clothing to the pole. Keep birds guessing by moving your scarecrow around in the garden. The best time to change its location is in the evening. The next morning's early birds will be surprised to find it in a different spot.

Weave a Rustic Homegrown Fence

Barbara Pleasant

Kids and dogs rarely mean to trample the dahlias or break the begonias, but the damage they cause while chasing errant balls or neighborhood cats can be severe.

Here's a pretty yet practical handmade fence that can save your garden from destruction and save your family from stressful discord.

This version is 12 feet long and 3 feet high, but you can make a smaller version if you want to create a low edging around flower beds. If you live near woods, you can gather your materials as you thin out unwanted undergrowth. Or, grow your own wood for weaving. If your own property lacks a supply of wattle-worthy wood, check with a local tree-trimming business or your local parks department to see if you can acquire what you need from them. The misguided pruning practice of "topping" trees causes them to produce a gold mine of growth that's perfect for wattle fence construction—loads of long, straight, whippy branches. If your neighbor is inclined to this type of arboreal abuse, offer to prune the afflicted tree of its resulting suckers (those long, straight stems) and put them to good use in your fence.

You Will Need

Tools: Pruning saw, loppers, pruning shears, hatchet, measuring tape, hammer, scissors

One 18-inch-long rebar stake

Small piece of scrap lumber

Five 4-foot-long, 2-inch-diameter posts

Thirty-two 4-foot-long flexible branches

Jute or twine

1. Use the pruning saw and loppers to gather your materials. Trim off stubs and leaves with pruning shears. Shape one end of each post to a point with a sharp hatchet.
2. Mark places for posts 3 feet apart. Use the rebar stake, topped with a piece of scrap lumber, to make guide holes for the posts. Pound the posts into the guide holes 12 inches deep. They may be slightly wobbly.
3. Starting at each end, weave flexible branches between the posts, alternating the position of each branch on either side of the posts. Use at least four horizontal rows of branches to make the fence sturdy enough to work as a barrier. As you weave, adjust the posts as needed to keep them upright. The fence will become sturdier as each row of horizontal branches is added.
4. When you are satisfied with the woven pattern of the branches, use jute or twine to tie the ends of protruding branches to adjacent horizontal branches to hold them in place. Trim off any awkward ends.
5. Weave jute or twine through the ends of the horizontal branches on both outside edges of the fence, lashing them to the outermost posts to keep them from sliding up and down. Trim the ends of the branches on the outside of the fence to make them even.

Grow a Living Fedge

Barbara Pleasant

What do you get when you cross a fence with a hedge? The answer is a fedge, which you can make by weaving fresh willow branches together, with their bases nestled into moist soil so they take root and grow. You can start a fedge with willow or other woody cuttings gathered from woods or roadsides. Or, use whatever

Continued ➔

green branches you have on hand, including those pruned from fruit trees, grapes, or forsythia or other flowering shrubs. As long as you make the fedge in spring, when deciduous plants are just emerging from dormancy, many of them will take root and leaf out.

In traditional fedges, branches are arranged diagonally, so they cross each other within the structure. However, you also have the option of setting branches into the ground vertically, so they grow straight up. A fedge can be temporary—lasting only a few years—or you can make it a permanent part of your landscape. If your goal is to establish a permanent coppice plot, you can plant your first cuttings in a fedge, and then cut all of the plants back to the ground after 2 years. In subsequent seasons, the plants will regrow into a hedge that will produce a steady supply of young branches to use in garden projects made of weavable woods.

You Will Need

Tools: Spade, handsaw, wire snips, staple gun

Three 5-foot-long wood posts

30 feet of 10-gauge wire

Twelve 8-inch-long willow stem tip cuttings (or cuttings from other deciduous plants)

Mulch for a 12-foot-long row

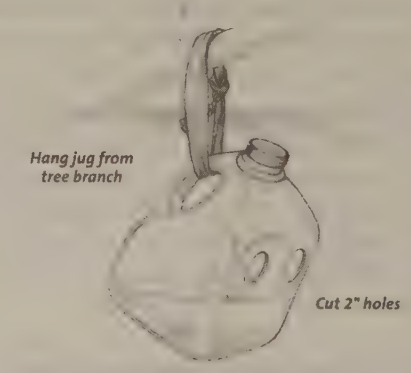
1. Prepare the soil in a 12-foot-long row by digging in organic matter and removing weeds, roots, and rocks. Set the posts in the ground, 12 inches deep and 4 feet apart.
2. Install 2 tiers of wire between the posts, with the bottom tier 12 inches from the ground and the top tier 36 inches from the ground. Wrap the ends of the wire around the end posts before snipping off the ends. Staple the wire to all three posts.
3. Push half of the cuttings into the ground 2 feet apart and 3 inches deep, setting them at a diagonal angle. Push the remaining cuttings into the soil 6 inches from the first set, crossing the cuttings so they form right angles. Water well.
4. As the cuttings begin to leaf out, remove any weeds and then mulch over the soil. Train the new growth to twine in and out between the wires.

Sweet 'N' Sour Codling Moth Trap

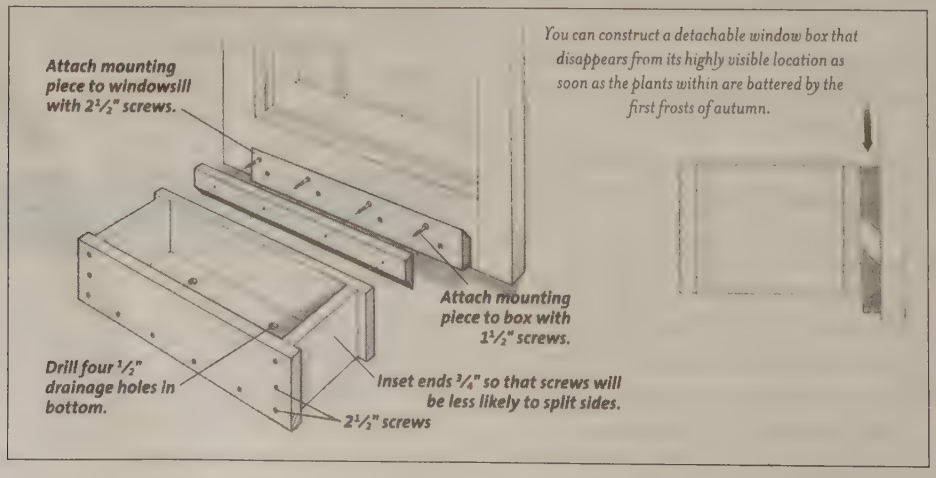
Roger Yepsen

For a nontoxic way of catching codling moths around fruit trees, mix up a brew of household ingredients.

1. Pour 1 cup of cider vinegar, 1/3 cup of dark molasses, 1/8 teaspoon of ammonia, and 5 cups of water into a plastic gallon jug. Put on the cap and shake well to mix.
2. Cut two or three 2-inch holes just below the shoulders of the jug.
3. Hang the jug from a fruit tree, passing a strip of cloth through the handle so that the holes are canted downward and won't admit rainwater.
4. Monitor the trap and replace the brew from time to time.



You can mix up your own attractant to lure codling moths to their deaths in this trap.



Attach mounting piece to windowsill with 2½" screws.
Attach mounting piece to box with 1½" screws.
Drill four ½" drainage holes in bottom.
Inset ends ¾" so that screws will be less likely to split sides.
2½" screws

You can construct a detachable window box that disappears from its highly visible location as soon as the plants within are battered by the first frosts of autumn.

A Detachable Window Box

Roger Yepsen

Winter weather is tough on wooden window boxes, shortening their serviceable lives. In particular, the planting medium will expand as it freezes, possibly causing the joints to fail. This design is easy to build, is light enough to manage easily, and can be lifted off of its support come cold weather. There's no need to paint (and scrape and repaint) the box because it's made of cedar and assembled with stainless-steel screws.

1. From 1 x 6-inch cedar boards, cut the sides, ends, and bottom to length. You'll also need to cut two mounting pieces, one that will be attached permanently to the windowsill and the other for the box itself. Note that one long edge of each piece has a 45-degree angle; you can make both pieces with a single angled cut down the middle of a 1 x 6.
2. Assemble the box by drilling pilot holes, then driving the screws. Drill the drainage holes in the bottom. Attach the other mounting piece to the windowsill, bevel side up as shown.
3. Line the box with a piece of plastic sheet, tucking in the corners. Punch drainage holes through the plastic over the holes in the bottom.
4. Mount the window box and either add a potting mixture or use individual potted plants.

A Bitter Pill for Cabbageworms

Some gardeners swear by tansy, a bitter herb long used medicinally as a vermifuge. Tansy has fallen out of popularity as a human tonic, but studies have shown that it also can cause imported cabbageworms to lay fewer eggs and to develop more slowly. Process 1 cup of tansy in 3 cups of water in a blender, filter through cheesecloth, and then spray on vulnerable plants.

Make a Plant Rack

Barbara W. Ellis

If you're sold on the benefits of starting seedlings under lights but need to conserve space in your basement or plant room, building a plant rack may be the solution. Ours is inexpensive and relatively easy to build.

TOOLS REQUIRED

Electric drill

Saw (circular saw or handsaw)

Hammer

Pliers

MATERIALS

Lumber-Shopping List

4 pcs. 2 x 4 x 8'

3 pcs. 2 x 3 x 8'

5 pcs. 1 x 3 x 8'

1 sheet (4 x 8') ½" A-C grade exterior plywood

Lumber-Cut List

You'll need to cut the lumber you've bought into the following lengths.

4 pcs. 2 x 4 x 63½" (vertical supports)

4 pcs. 2 x 4 x 18" (horizontal supports)

6 pcs. 2 x 3 x 48" (cross supports)

3 pcs. ½ x 3 x 47¾" plywood (tray bottoms)

6 pcs. 1 x 3 x 47¾" (tray sides)

6 pcs. 1 x 3 x 16½" (tray ends)

Hardware

2 dowels, 5/16" x 48"

3 double-tubed, 48" fluorescent light fixtures with hangers

12 lag bolts 5/16" x 3½" with flat washers

3 broom handles or 1" dowels, 48" long

6 finishing nails 3d

2 pcs. window sash chain, 4' each

2 screw hooks

36 pcs. 1½" #6 flathead wood screws

4-mil plastic sheeting

1. Drill 5/16-inch holes for the lag bolts in the vertical supports, making sure they are spaced evenly so the trays they support will be level.
2. Drill holes for dowels in the ends of the vertical supports and corresponding holes in the horizontal supports as shown in the illustration on the next page. Cut dowels to 4-inch lengths and glue the assembly together.
3. Drill ¼-inch pilot holes that are 2 inches deep in the ends of each cross support. Bolt the rack together with the lag bolts and washers.
4. To make the tray bottoms, drill and countersink pilot holes through the tray bottoms into the tray sides and ends. Fasten tray bottoms to sides with flathead wood screws. For a waterproof liner, spread 4-mil plastic on the tray bottoms

Continued ➔

and up the sides, and staple or tack it in place. Slide the finished trays onto the rack.

5. To mount the fluorescent lights, first twist screw hooks into the underside of the horizontal supports at the top of the rack. Hang a 4-foot piece of window sash chain from each hook. Drive finishing nails partway into the ends of three broom handles, slip the broom handles through the hangers on the light fixtures, and insert the nail ends into loops of the sash chain. Adjust the lights up or down by moving the nails to higher or lower loops.

The three lights combined use about 260 watts per hour (40 watts per tube plus ballast).

For quick germination, start your seeds on the rack's top level, where the soil can be warmed by heat rising from the lower lights. Once the seedlings have sprouted, move them to a lower level and start a fresh seed tray on top.

Making a Portable Cold Frame

Barbara W. Ellis

This simply designed cold frame is tried and true—as well as easy and inexpensive to build. Its dual window-positioning system is a convenient feature; rods attached to both sides of the frame can be raised to any of three positions to hold the glazing open wide when full ventilation is desired or while tending the plants inside. When only a small amount of ventilation is needed, wooden cams attached to the front adjust to hold the lid open from 1 to 3 inches.

This frame is designed to use an old storm window measuring 32¼ by 62⅜ inches as the glazing. If you have a window with different measurements on hand, adjust the width and length of the frame accordingly. The width of the frame should be 1 inch less than the width of your window; the length of the frame should be 1⅛ inches less than the length of your window. When adjusting the design, retain the height of the front and rear walls used here, but allow the slope of the window and the width of the box to change as necessary.

This frame can be easily dismantled for storage. The only maintenance it should need is periodic repainting and caulking.

TOOLS REQUIRED

Electric drill

Saw (table or circular)

Hammer

Pliers

Screwdriver

MATERIALS

Lumber-Shopping List

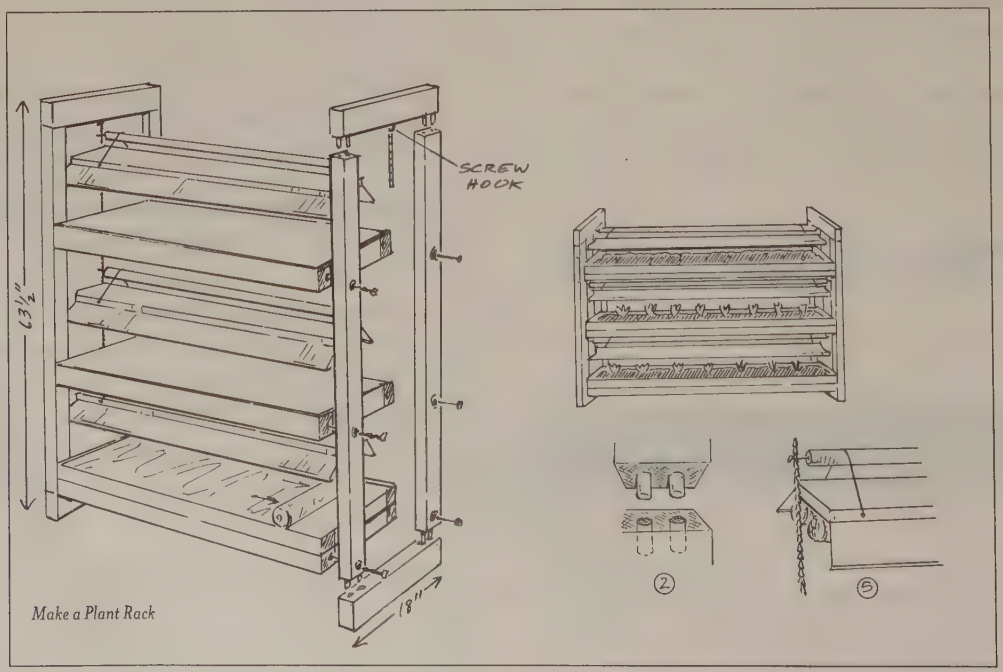
1 pc. 1 x 4 x 10'

1 pc. 1 x 2 x 5'

1 sheet (4 x 8') ½" A-C grade exterior plywood

Lumber-Cut List

You'll need to cut the lumber you've bought into the following lengths. Use pressure-treated lumber or untreated pine painted



Make a Plant Rack

with a preservative. It's best to measure and then cut the pieces as you assemble them to be sure they fit together correctly.

2 pcs. 1 x 2 x 18½" (rear vertical cleats)

2 pcs. 1 x 4 x 58¼" (front and rear horizontal cleats)

2 pcs. 1 x 2 x 6" (front vertical cleats)

Hardware

2 hardwood dowels 5/8" x 36"

1 wood-frame storm window 32¼" x 62⅜"

10 pcs. 1½" #8 flathead wood screws

2 carriage bolts 5/16" x 2" with flat washers and wing nuts

3 pcs. 3" tee hinges with fasteners

4 pcs. 1½" eye screws

12 finishing nails 4d

1¼" aluminum nails

½ pint waterproof glue

1 quart exterior-grade primer/sealer

1 quart exterior-grade enamel

1 quart copper naphthenate wood preservative

1. Lay out the front-, rear-, and side-wall panels on the sheet of plywood. Cut out all four pieces. The rear-wall panel will be ½ inch wider than its final size, so its upper edge can be beveled (see step 4).
2. Fasten the vertical cleats across the ends of the rear-wall panel using waterproof glue and 1¼-inch aluminum nails. Avoid nailing at the three points on each end where screws will be inserted to hold the side panels in place in step 7.
3. Fasten the horizontal cleat to the upper edge of the rear-wall panel, between the two vertical cleats and flush with the top of the rear wall, using waterproof glue and 1¼-inch aluminum nails. Avoid putting nails in areas where hinges will be attached in step 9, or near the upper edge of the panel, which will be trimmed away in step 4.
4. To bevel the top edge of the frame, start by laying the rear-wall panel down with the cleats facing up. Position one of the side panels against it, overlapping the edge and making sure the bottom and back edges of each panel are aligned flush. Scribe or draw a line across the end of the rear-wall panel and vertical cleats where they are crossed by the upper edge of the side-wall panel. Do the same using the other side-wall panel on the opposite end. This establishes the angle of the bevel. Now connect the two slanted lines by scribing or drawing across the length of the rear-wall panel on the front and back. Using a table saw or portable circular saw, rip and bevel the top edge of the rear panel.
5. Attach the front vertical cleats to the front-wall panel using waterproof glue and 1¼-inch aluminum nails. Avoid nailing where screws will be inserted from the side in step 7.
6. Attach the front horizontal cleat to the front-wall panel, flush with the upper edge of the panel, using waterproof glue and 1¼-inch aluminum nails.
7. Temporarily fasten the side-wall panels to the rear- and front-wall panels using 4d finishing nails or small brads. Drive the nails only partway into the wood for easy removal later. Drill a pair of 3/32-inch-diameter pilot holes centered 13/16 inch from the front edge of each side panel. Drill the first hole 1½ inches above the base of the panel and the second 5 inches above. Center and drill three pilot holes of the same diameter through the back edge of each side panel. Install 1½-inch #8 flathead wood screws in the holes; then remove all temporary fasteners.
8. Cut the two window-positioning cams out of ½-inch plywood. Drill a 5/16-inch-diameter hole through each cam. Center and drill two 5/16-inch-diameter holes each 4¼ inches above the bottom edge of the front panel and 15 inches from the ends to accept the bolts for fastening the cams. Attach the cams to the outside of the front panel, using 5/16-by-2-inch carriage bolts with flat washers and wing nuts. Install the bolts from inside the panel.
9. Position the window on top of the cold frame so the rear edges of each are flush. Center the window over the frame so both edges hang slightly over the outer edges of the frame sides. Fasten the window to the frame using three 3-inch tee hinges. Attach a hinge 4 inches from each end and one in the center. Check to make sure the window opens and shuts properly.
10. To attach the dowel support rods, fasten the 1½-inch eye screws into two linked pairs. Install one end of each pair into a front panel vertical cleat, 4¼ inches above the base of the cold frame. Then drill a ⅛-inch-diameter pilot hole into one end of each 36-inch wooden dowel. Screw the remaining eye screws into the dowels to fasten them to the frame.
11. Drill six 1 1/16-inch-diameter holes into the window frame, on the underside about halfway through the wood. You'll need three holes on either side. Locate one pair of holes 16 inches from the rear edge of the window; space the other two pairs on 4-inch centers toward the front. Drill the holes at an angle (approximately 65 degrees) to accommodate the dowel support rods when the window is in the open position.
12. Dismantle the cold frame to prepare it for planting. Sand all sharp edges and coat all bare wood surfaces with copper naphthenate wood preservative. After allowing the preservative to dry completely, paint the entire frame and, if necessary, the window frame with an exterior-grade primer/sealer.
13. Reglaze the window if the glazing is loose. Fill in any cracks or holes in the window or frame with caulk. Paint the wooden parts of the cold frame with two coats of good-quality exterior-grade enamel. Reassemble the cold frame when you are ready to use it.

Build a Planter

Barbara W. Ellis

This 8-cubic-foot planter is versatile, durable, portable, and protective for both ornamentals and container food crops. It can be used to grow a tree rose, a dwarf fruit tree, or a mixture of vegetables and flowering annuals on porch, patio, balcony, or deck. Fitted with casters, it can easily be rolled indoors in the fall to grow by a bright kitchen window or in a greenhouse over the winter, and then rolled back outdoors in the spring. It will last for many years.

TOOLS REQUIRED

Screwdriver

Electric drill

Miter box and saw

Saw (crosscut or electric)

Paintbrush

MATERIALS

Lumber-Cut List

Use redwood, cedar, or pressure-treated wood.

6 pcs. ¾ x 7¼ x 21¾" (base)

12 pcs. ¾ x 7⅜ x 23¾" (side slats)

4 pcs. ¾ x 1½ x 25¾" (band)

4 pcs. ¾ x 2 x 26¾" (cap)

16 pcs. ¾ x 1½ x 22¼" (battens)

Hardware

#6 x 1¼" galvanized wood screws

12 to 16 pcs. #6 x 1⅝" galvanized wood screws (for side corners only)

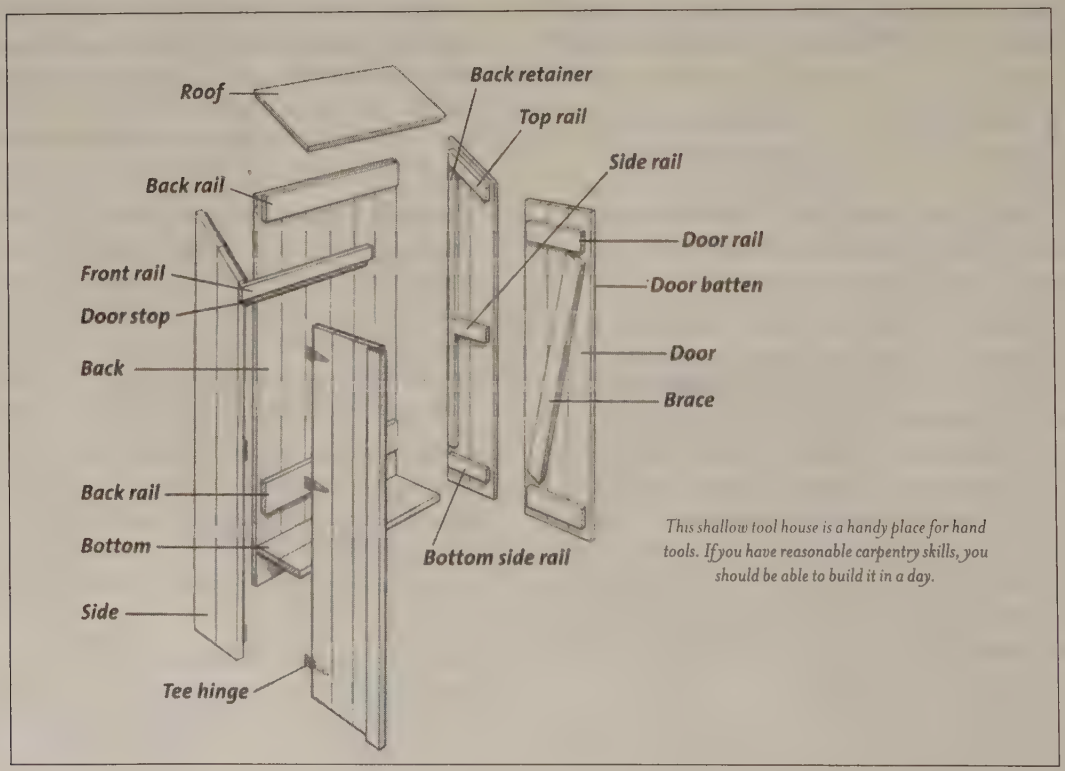
4 pcs. 3½" corner braces

4 heavy-duty casters

Clear wood finish for exterior wood or other ultraviolet inhibitor

1. **Base.** The 22¾-inch-square base consists of two layers, with three boards per layer, running in opposite directions. The ½-inch gap between each board allows for drainage; four drainage holes are created in the center of the planter, as well as a hole near each of the four corners. To assemble the base, screw the two layers together, drilling from the bottom layer of boards into the top layer. Attach the casters to the base. Throughout the construction, predrill all holes.

2. **Sides.** Screw individual side slats into the base, allowing the sides to completely cover and extend about ½ inch below the base, depending on the size of the casters. The sides of the



This shallow tool house is a handy place for hand tools. If you have reasonable carpentry skills, you should be able to build it in a day.

planter should be 1¼ inches above the ground. For added strength, use three or four #6 1⅝-inch screws on each side corner.

3. **Band**. Use the miter box to cut the ends of the four band pieces to join at corners. Notch corners of the four pieces 1/16 x 3½ inches to accept corner braces. Screw the bands into the sides. Attach the corner braces to band corners at top.

4. **Cap**. Use the miter box to cut the ends of the four cap pieces. Screw the cap pieces into the top of the planter so the cap covers the top edges of the side slats and braced band. The inside edge of the cap is flush with the inside of the planter. The outside edge of the cap extends slightly beyond the band. Predrill all holes.

5. **Battens**. Screw the battens into the sides, four battens per side, so the side slat seams are covered. The corner battens are flush with the side edges. Stagger the screw holes on either side of the seams.

6. **Finish**. If you've used redwood or cedar, paint the outside of the planter with a clear finish. It is not necessary to paint the inside of the planter. Add 1 inch of gravel to the inside bottom of the planter for additional drainage. Indoors or on a wooden deck, be sure to use a drip tray beneath the planter.

A Tool House

Roger Yepsen

WHAT YOU'LL NEED

32 feet 1 x 2 pine
16 feet 1 x 4 pine
16 feet 1 x 5 pine
96 feet 1 x 6 pine
1/6 sheet ½-inch CDX plywood
#6 x 1¼-inch galvanized screws
#6 x 1⅝-inch galvanized screws
#6 x 2-inch galvanized screws
Six 4-inch galvanized tee hinges
One 3-inch barrel bolt

Gardening requires enough labor without making repeated trips between wherever you stash implements and the garden itself. An attractive tool house, just deep enough to hold a row of commonly used hand tools, can be a great convenience. The structure is just a box, basically, with a little shed roof. It can be attached to the wall of your house or garage, or anchored to a sturdy garden post. To keep the wood from rotting at the lower edge of the tool house, the sides rest on either bricks or concrete blocks. The inside of the structure measures 9 inches deep, 34 inches wide, and 6 feet high. Although you can make all the cuts needed for the project with a handsaw, the work goes much more quickly with a circular saw. The construction is of solid wood, capped by a plywood roof, and assembled with both screws and water-resistant polyvinyl acetate glue. Parts are put together with glue on their mating surfaces, then clamped before driving the screws. Each door is hung with three tee hinges, and they are secured with a barrel bolt.

The instructions and drawing given here offer general ideas on how to go about building a tool house. If you don't have basic carpentry skills and tools, you can ask a carpenter to do the work.

1. To limit waste, buy 6-foot or 12-foot boards for the 1 x 6s used to make the sides, back, and doors—not 8-footers.

2. Begin by constructing each side, attaching the three rails to its inside surface. Cut the roof pitch at the top of the side, using the top rail as a guide. Attach the back retainers to each side, placing one above and one below the middle rail.

3. Make the back, attaching its two rails to the back boards. Leave a little space between each of the back boards to allow them to expand and contract with changes in the weather.

4. Attach the back to the sides.

5. Make the bottom by attaching two boards into the bottom side rails.

6. Make the front rail, which ties the top of the tool house together.

7. Add the roof, attaching it by driving screws into the pitched sides.

Basic Paving Installation

Paving materials vary a great deal from region to region, based on what's available, but installation techniques for most materials are very similar. In areas where the ground freezes in the winter, lay paving on 2 inches of leveled sand over a base of 4 to 6 inches of tamped gravel. Where the ground does not freeze, you can install paving on a layer of leveled sand without the layer of gravel beneath it. Pour concrete directly on sand, eliminating the gravel. Stone patterns, tiles, and edgings are usually set in a 1-inch-deep mortar bed over sand.

Continued →

8. Make each door from three boards, attaching its two rails and the diagonal brace to the back surface.
9. Hang each door with three tee hinges, then make the door stop, which closes the gap at the top of the doors and gives you a place to mount the *strike* (or top component) of the barrel bolt. Attach the door stop to the back of the front rail.
10. Make the door batten and attach it to the outside edge of one door. The batten acts as a lip to hold the other door closed.
11. Mount the barrel bolt at the top of the door with the batten. Mount the strike on the door stop.

Pave the Way to Garden Pleasures

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

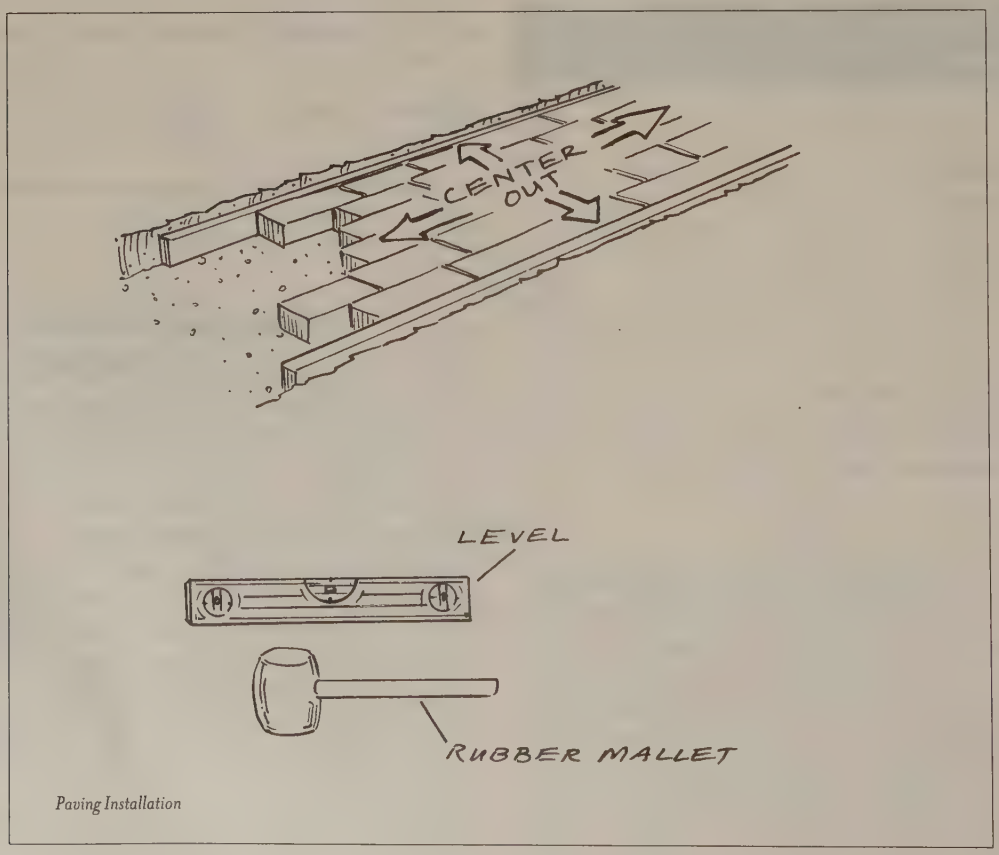
Although most gardeners prefer plants to paving, there are many places in the landscape where paving is useful, appropriate, and labor saving. Installing a paved path once, for example, is a much better use of your time than repeatedly working to maintain part of your lawn that's trampled by traffic.

Find the Right Paving for Your Project

Start your paving project with a mental design. Consider how you'll use the paved area. As a patio? A lightly traveled path? How big is the area you want to pave? Choose paving that harmonizes with your home and is appropriate for the intended uses. You can install some paving materials, such as bricks, in different ways to create varying visual effects. For a large paved surface, you might choose to combine different materials to make it look more interesting.

Asphalt, bricks, concrete, stones, tiles, and wood are all types of paving that may find a place in a home landscape. While you can install most paving options yourself, you may choose to hire a contractor to install some types, such as asphalt and large-scale concrete projects. One advantage of brick and precast concrete pavers is that you can install paving at your own pace. You can finish your project in a day or gradually, as you have time to work on it.

Concrete. Concrete is a familiar and inexpensive paving. It is durable, needs little or no maintenance, and is more versatile than most people realize. You can vary its color, or seed it with stones to change its texture. It is unforgiving, however, and preparation before pouring is critical since you can not stop once you have begun.



Paving Installation

Concrete requires sturdy forms to hold its weight in place while it hardens, and you must have tools, such as edgers and floats, to give the surface the proper finish. You can mix concrete in a wheelbarrow or trough, or you can rent a portable motorized mixer.

Brick. Brick paving is one of the best choices for do-it-yourself home projects. Bricks come in a variety of colors and textures, and they are easy to plan with. Brick paving absorbs moisture so it dries quickly after a rain, doesn't become slippery, and stays cool in summer.

It is relatively simple to estimate the amount of material and cost because of the uniform size (about 2 x 4 x 8 inches), which is compact and easy to handle. You can lay bricks in many patterns; mixing patterns adds interest to large paved areas and helps define borders.

Precast pavers. Precast concrete pavers offer another easy-to-install paving option. They come in many colors and shapes, and are dense, durable, and of uniform size. Some styles fit together in interlocking geometric patterns. Install precast pavers on a base of sand over gravel, with sand joints between pavers. Some styles are shaped with holes in them that allow you to grow grass or other groundcovers over the paved area.

Add a Layer of Prevention

If you're laying pavers over sand rather than setting them in mortar, it's worth your time to put a weed-blocking barrier over the sand. You can use landscape fabric, cardboard, layers of newspaper, or any other light-excluding materials, as long as you keep the surface level. Although it adds a step to your paving installation, it will keep weeds from coming up through your pavement for years to come.

Paving Installation: Careful Planning Smooths the Way

1. **Outline the area you plan to pave.** Use a string stretched between stakes to outline the area and serve as a digging guide. It also will help you determine the amount of material you'll need. Use a hose to design curved edges or draw them on the ground with lime or bonemeal. Measure frequently with your tape measure to maintain equal distances between edges.

   If you're installing a walkway, skip to Step 5 and install edging strips to serve as your digging guide.

2. **Stretch a string as a reference point.** Stretch your string a few inches to a foot above the ground and use a line or carpenter's level to level it. The string will serve as a reference point as you dig out the bed for your paving and base materials. If you're installing a paved area next to your house, slightly slope the strings away from the house for drainage—about 1½ inches for every 8 feet.

3. **Excavate the site.** Measure down from your strings to help keep the bed level as you dig. Remove enough soil to accommodate the depth of your base materials plus your paving. Stretch a string diagonally across the area and measure down from it to check the depth of the bed in the middle of the site. Add more stakes and stretch more strings as needed.

4. **Level the bed and add gravel.** Use a rake to level the bed, then add gravel. Use a hand tamper or mechanical compactor to firm it and remove air pockets.

5. **Add sand and level it.** Lay 2 inches of coarse sand over the gravel and level it with a *screed*, a straightedge that you pull across the sand at a constant height. It knocks down high spots and lets you see where to fill in low spots.

   Screed bars work like rails that the long, straight screed slides over. For wide areas like patios, lay lengths of 2 x 2s on the gravel base to provide screed bars for the sand. If you are installing a path that has an edging, it can serve as the screed bars. Nail a board that fits between your edgings to a longer board that will lay across them to smooth the sand base in a path.

6. **Set the pavers.** Once the sand is level, begin setting your pavers, leaving about ⅛ inch of space between each of your bricks, precast concrete pavers, or tiles. Work the pattern from the middle out toward the edges, so any discrepancies are less noticeable or can be accounted for if cutting is necessary. Measure frequently to ensure the pattern is straight. It's easy to pry up stones, bricks, or pavers and reset them as needed. A rubber mallet for easing the pavers into position and a level for ensuring their evenness are handy at this stage.

7. **Install edging.** An edging will hold your paving in place and define the paved area. You can use a redwood 2 x 4 set on edge and staked firmly in place, a row of bricks set on edge, or heavier paving units made specifically to serve as edging. The edge paving can be set in a mortar base to help hold the entire project together.

   Edging usually completes the installation, but for a walkway it may come at the beginning. Set with the top at final grade, it serves as both a digging guide and as screed bars for leveling the sand. Maintain exact measurements between edgings in this case so paving units fit. A temporary, moveable edging set on grade can also serve as screeding.

8. **Spread fine sand over the finished paving.** Sweep it into the cracks until they are full. Sprinkle the paving with a garden hose, then repeat with more sand.

Continued →

TOOLS NEEDED FOR PAVING INSTALLATION

- Broom
- Rubber mallet
- Carpenter's level
- Saw
- Hammer and nails
- Shovel
- Hand or machine compactor
- String and stakes
- Rake
- Tape measure
- Wheelbarrow

Step-by-Step Steps

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

To transform a slippery slope into easy-to-use steps, you'll first need to know the rise and run of the slope. To measure the *rise*, hold a 2 x 4 or a long pole horizontal and level, with one end resting at the top of the slope. Measure the distance straight down from your pole to the bottom of the slope. To measure the *run*, place a pole upright and level at the bottom of the slope, and measure the horizontal distance to the top of the slope.

Now do some simple math to see how many steps you'll need. Divide the rise of the slope by the desired height of each step. The result is the number of steps. Now divide the run of the slope by the number of steps to find the length of each tread. Check the table to see if your treads and risers are properly proportioned; if not, adjust your numbers until you achieve the right balance.

Tread-to-Riser Relationships

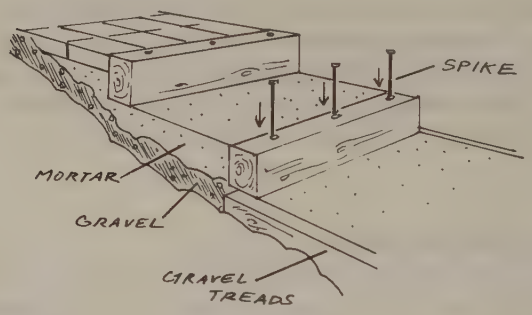
Use these recommendations to design steps that will be easy to negotiate.

Tread (inches)	Riser (inches)
19	4
18	4½
17	5
15	5½
14	6
13	6½
12	7

Steps Can Ease Your Ups and Downs

Steps add an inviting aspect to the landscape and create transitions from one part of your yard to another. They also save you the hassles (and hazards) of scrambling up and down slopes and offer a solution for steep, hard-to-mow areas. Well-planned steps are safe and easy to use because they maintain the right proportions between treads (the part you walk on) and risers (the vertical parts). Steps on gentle slopes work best with low risers and wide treads, while steeper slopes need taller risers and narrower treads. Use the method shown on this page to find the total rise and run for your slope. With that information, you can work out how many steps you need and how much material it will take to build them.

Let your steps conform generally to the slope rather than trying to shape the slope to fit the steps. It means less work for you and a more comfortable climb. To make your steps easier to use, plan for a width of at least 4 to 5 feet, if your site and materials will allow it. Be flexible with your design, letting the treads extend over flat areas to form short pathways where the slope flattens, then rises again.



1, 2, 3, Basic Steps

1, 2, 3 Basic Step Installation

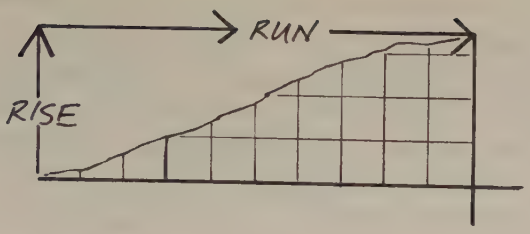
Follow these steps to install yours.

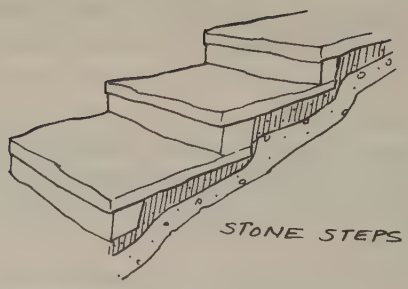
1. **Mark the risers.** Use stakes to mark both ends of each riser. Use a shovel to shape the slope into rough soil steps, using the stakes as guides. You may need a pick or mattock to accomplish this task.

   The tread of each step is just a short section of paving. Leave enough space between risers for the necessary gravel and/or sand base, in addition to the depth of the tread material.

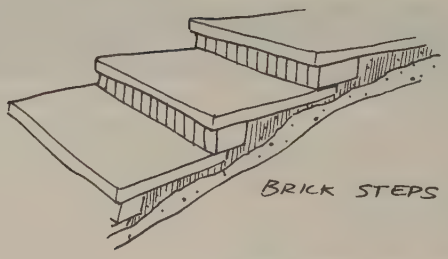
2. **Install the steps.** Work from the bottom to the top of the slope. Alternately set risers and treads in place. Use a carpenter's level to keep them horizontal.

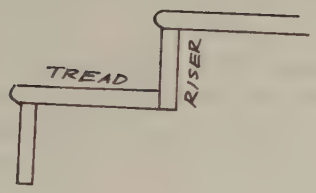
3. **Grade the site.** After the steps are installed, grade the soil on either side to slope naturally down to the steps. Border your steps with stones or plantings of perennials, herbs, groundcovers, or low shrubs to give them a finished look that's easy to maintain.





Step Options





Step-By-Step Steps

Step Options

Timber steps. Steps constructed with 4 x 6 timbers for risers are the simplest to build. You can stack two 4 x 4 timbers together to make risers for steeper slopes. Drill into the timbers and tie them to the soil with galvanized metal stakes or spikes (basically huge nails).

Brick or concrete steps. You could also make the risers from bricks or from concrete poured into simple forms. Pave the treads with brick, gravel, wood chips, or groundcovering plants. If you choose to make brick treads, set them in a base of 1½ to 2 inches of mortar over 3 to 4 inches of gravel. Treads of gravel and other loose materials will require edging to keep them in place.

Stone steps. Fieldstone steps with risers of smaller stones look natural in informal landscapes. This type of step can wind more easily because of the varying size of the components. To make wider steps, set two or more fieldstones side by side on a wider bed of small stone risers. For stability, set the small stone in a mortar bed with at least ½ inch of mortar between the small stones and the fieldstone cap. As with brick treads, lay the mortar on top of 3 to 4 inches of gravel. If you don't want to see the mortar, rake it from the face of the joints before it sets completely. You could also use bricks to form the risers for these steps, or stack two fieldstones with mortar beneath and between them. Set the bricks and slate in mortar beds underlaid with gravel.

Do a Little Make-Sure Math

Make certain the layout of your deck is rectangular. From one corner stake (stake A), measure 3 feet out along the outlining length of string toward another stake (stake B); fold a piece of masking tape over the string to mark that point. From stake A, measure 4 feet along the string toward the stake at the other corner (stake C); mark that point with a second piece of tape. Measuring from tape mark to tape mark across the hypotenuse of the triangle, the distance should be exactly 5 feet. If it is not, adjust the position of stake B or C until the measurement is 5 feet and your deck is a true rectangle.

Low-Care, Easy-to-Build Deck

Barbara W. Ellis, Joan Benjamin, and Deborah L. Martin

Building a deck is not automatically a major investment involving a contractor. You can add a simple deck to your landscape in about a weekend, using tools you probably have

Continued ➔

at home. Size and place the deck to suit your needs—since it's freestanding, it can go anywhere. Precast concrete piers support the deck's 4 x 4 beams; these are topped by a deck of 2 x 6s.

Begin by deciding where you want your deck. Check the site for sun, drainage, and slope of the land. It's okay if the site slopes slightly, but the more level it is the better. If you're building your deck next to your house, any slope should be away from the house.

Decide on the size of your deck and make a plan to help you figure out how many beams, piers, and deck boards you need. Space your beams (the distance the deck boards must span) no more than 3 feet apart on center (from the center of one beam to the center of the next). Keep the space between the piers, along the length of beams, no more than 5 to 6 feet on center. If your deck is next to your house, leave a ½- to 1-inch gap between the deck and the house.

Simple Steps to an Easy Deck

1. **Lay out your deck with stakes and string.** Use two stakes to mark each corner; place one about 6 inches out on a straight line with one side and the other stake 6 inches out on a line with the other side. When you stretch strings between the stakes, the strings will cross at the corners of the deck and form its outline.

   Stretch string between the stakes and level it with a carpenter's level or, preferably, a line level. The string helps you visualize the deck, determine where you need to add or remove soil, and level the piers. Remove all sod in the deck area.
2. **Lay out the piers.** Working from your drawing, measure in from the strings and lay out the piers. Drive a stake to mark the center of each pier position. Set the piers back from the edges of the deck to keep them out of sight.
3. **Dig a hole for each pier.** Dig deep enough to accommodate a 6- to 8-inch gravel base plus most of the height of the pier. Stretch additional strings, as needed, to help you position your holes and measure the depth to dig. Remove the soil in a wheelbarrow, add gravel to each hole, and tamp the gravel to remove any air pockets. If you don't have a good tamper handy, use the end of one of your 4 x 4 beams. In areas where the ground does not freeze in the winter, you can set your piers in smaller holes with just a 2-inch layer of sand in the bottom.
4. **Set the precast piers onto the gravel.** Adjust the height, level, and exact alignment according to string lines and a carpenter's level. Backfill with soil around the piers. Check the accuracy of your work with a tape measure from time to time to make sure the piers are spaced properly.
5. **Spread landscape fabric.** To prevent grass and weeds from growing up between the deck boards, spread landscape fabric or other light-blocking material over the area. Cut an X in the fabric over each pier and pull it down snugly around them.
6. **Saw the 4 x 4 beams to length.** Lay them across the piers and nail them in place. Each pier will have a wooden nail block or metal hardware precast in it for nailing the beam. Align the ends of the beams with a string or a straightedge, or by careful measurement.
7. **Nail on the decking.** Laying out the decking can be tricky, but with a small deck you can lay out the boards before nailing them. Snap chalk lines as nailing guides, then attach each 2 x 6 deck board to the beams with two 16d galvanized nails at each beam. You can use ring-shank or twist nails for stronger hold. Use a 16d nail to space between the boards as you nail them. Let the first and last deck boards overhang the ends of the beams about an inch. You can adjust this somewhat, or adjust the spacing between the boards to make them fit evenly. If necessary, you can narrow the width of one board to fit the width of the last space.

As you work, use a straight edge to align all the deck boards on one end; let the other end extend slightly long. After all the boards are nailed in place, measure from each side of the deck and snap a chalk line to mark the edge of the boards. Cut along this line with a portable circular saw to even the ends. Soften up this hard edge with a rasp. Stain and/or seal the cut ends and your deck is complete.

Barbara Pleasant

When gathering vines from wild or cultivated grapes for making wreaths, use pruning shears to nip off the leaves (save pretty young leaves for cooking). Leave the curled tendrils intact. If you will not be using the vines right away, wind them into a coil in a large washtub or laundry basket, and cover them with a wet towel.

You can make grapevine wreaths freehand, but it's easier to use a form made from a piece of scrap plywood. Decorate your wreath after it has dried.

You Will Need

Tools: Measuring tape, pencil, hammer, pruning shears

One 2-foot-square piece of scrap plywood

Four 4-inch nails

4 or more pieces of grapevine at least 4 feet long

Several 8-inch-long pieces of string

1. Draw an 18-inch-wide circle on the plywood, and hammer four 4-inch nails at equal intervals around the circle. Hammer them only as deep as needed to hold them secure.
2. Holding the thickest end of a cut piece of vine, wind it loosely around the nails, and then tuck in both of the ends. Repeat with as many vines as you like.
3. To help hold the wreath tight, tie it together with pieces of string before slipping it off of the form.
4. Lay the wreath on a flat surface to dry, and expect it to shrink a little. Should a wreath begin to warp as it dries, weight it with a board held in place with a brick.

Make a Woven Wheat Good Luck Charm

Barbara Pleasant

For thousands of years, people in different parts of the world have captured and preserved the fertility of summer by making woven wheat charms, which were hung in the kitchen through winter as a blessing for the house. The following spring, many rituals involved burying the woven wheat in the garden as a good luck charm for a bountiful season.

You Will Need

Scissors

9 stems of wheat, with the seed heads intact

Three 10-inch-long pieces of waxed dental floss

2 heavy books

1. Gather almost-mature wheat stems, with the whiskered heads attached, and hang them upside down in a bundle to dry. If you don't grow your own wheat, ask permission to gather some stems from a farm field, or look for dried wheat stems in craft stores.
2. When you're ready to weave, soak 9 dried wheat stems in warm water for 15 to 30 minutes to make the stems pliable.
3. Working on a flat surface, tie the wheat stems together with dental floss just below the seed heads. Separate the stems into three sections. Tie the middle three stems together three inches below the cluster of tops.
4. Braid the 3 stems on one side of the cluster, and then braid the other 3 stems. Curve the ends of the braids together to form a heart shape, and tie them tightly to the center bunch of stems. Trim off the ends.
5. Arrange the seed heads the way you want them, and place the weaving between two books to dry for at least 3 days. Hang your finished weaving on a wall or over your kitchen door.

Make a Broomcorn Whisk Broom

Barbara Pleasant

Making a perfect broom requires practice, but anyone can make a pretty yet primitive whisk broom. The secret is to bind the stems together as tightly as you can, which is best done with the help of a handy doorknob. You can use a straight stick or dowel for the handle, or turn your broom into an art piece by using a curved branch of rhododendron or other gnarled wood.

You Will Need

Tools: Ruler, drill, hammer, wire snips, scissors

About ½ bushel of cleaned broomcorn tops

One 18-inch-long stick, 1 inch in diameter, or an old wooden broom handle

One 2-inch-long finishing nail

One 36-inch-long piece of flexible wire

One 24-inch-long piece of cotton string

1. Harvest the seed-bearing tops from mature broomcorn, and hang them in small bundles to dry for several days. To remove the seeds, lay several stems on a flat surface and pull a ruler over them until the seeds break free.
2. Drill a small hole through the handle, one inch from the end. Tap the finishing nail through the hole, so that ½ inch (or more) of the nail extends on either side of the handle. Attach one end of the wire around one end of the nail, leaving 3 inches of wire extending outward from the nail. Attach the other end of the wire to a post, doorknob, or other stationary fixture.
3. Arrange a handful of broomcorn stems around the nail, with the tops of the stems one inch above the nail. Pull the wire taut, and rotate the broom to wrap the wire around the stems.
4. Repeat Step 3 twice, until the broom is full and tight and the nail is completely covered. Wind the two wire ends together tightly, and trim the ends.

Continued →

5. Tie the string around the bundle, just above the nail. Wind it around the bundle tightly several times, and tie off the ends. Use scissors to trim the tops and bottoms of the broomcorn stems.

Make a Batch of Potpourri

Barbara Pleasant

Why spend money on artificial air fresheners when you can create your own right at home? Making potpourri is a great way to use up odds and ends of dried herbs and flowers, and you can add little pinecones, seeds, or even dried bits of fruit if you like. There's no one set recipe for potpourri, so it's easy to tailor the look and fragrance of each batch to make one-of-a-kind creations.

To pump up the fragrance of potpourri, you will need one or more small bottles of pure, organic essential oil—highly concentrated extracts made from fragrant plants, which are available at health food stores. Most retail displays include tester bottles, so you can sniff before you buy. If you can't decide, choose essential oils based on where you plan to use your potpourri. Lavender oil is quite popular for closet sachets and active living areas; some people like rose oil for potpourri kept on bedside tables; and various citrus scents are always welcome in the kitchen.

Your potpourri will hold its scent longer if you use a fragrance fixative such as orris root, which is made from a type of iris. Craft stores sell other fixatives, too, such as calamus (which has a mild fruity scent) and spicy-smelling benzoin. However, orris root is widely available and works well in any type of potpourri.

You Will Need

Tools: Measuring spoon, wooden spoon, scissors

1 package of orris root crystals or other fixative

1 small bottle of pure, organic essential oil

1 pint-size glass jar with lid

6 cups of dried flowers, herbs, and seedpods

One 2-quart airtight glass or plastic container

1. Place 3 tablespoons of fixative and 15 to 20 drops of essential oil in a glass jar. Mix lightly with a wooden spoon and screw on the lid. Set aside for 2 days.

2. Select materials for your potpourri that include colors and scents to complement the room where you'll display your potpourri. Use scissors to cut them into small pieces. Place the materials in an airtight glass or plastic container.

Great Things to Do with Dried Flowers

- Press individual blossoms within the pages of a heavy book. Enclose the dried blossoms in plastic laminating sheets to create beautiful bookmarks, or glue them inside homemade greeting cards.
- Decorate a Grapevine Wreath with dried flowers and foliage; change the dried materials every few months to fit the seasons.
- Make a seasonal table display by combining dried flowers, seed heads from grains and grasses, and ornamental gourds in a large oval platter.
- If dried blossoms break off from their stems, use a hot glue gun to attach them to gift-wrapped boxes, baskets, wreaths, and other decorative objects.
- Turn a perfect dried blossom into a unique accessory by tucking it into your hair barrette or ponytail holder.
- Use short-stemmed dried flowers to make a tiny arrangement in a pretty teacup. Place an inch of dry sand in the teacup to help hold the stems in place.

Making More Light

The more seedlings you grow indoors, the more light you will need. Ordinary fluorescent shop lights work well and are widely available in 24- and 48-inch lengths. Look for a model that includes a reflective hood, and suspend it from the ceiling with hooks and chains. In addition to providing the light your plants need to grow, an illuminated group of seedlings brings a cheery note to any room.

3. Add the infused fixative to your dried materials, and toss everything together lightly with the wooden spoon. Put on the lid, and place the container in a dry, dark place for 2 weeks.

4. Place your finished potpourri in an open bowl to use as an air freshener, or tuck it into cloth pouches to use it as drawer or closet sachets.

Make a Bottle Gourd Candle Holder

Barbara Pleasant

You can make a candle holder from any size of bottle gourd, but it's a great use for very small ones. Remember that gourds are flammable, so do not leave your candle holder unattended or allow the candle to burn very low.

This is a good starter project to introduce you to gourd crafting. Be as creative as you like with the outside finish. Plain shoe polish or furniture wax are all you need to give your gourd a natural finish, or you can use paints, leather dye, or a coat of clear polyurethane.

You Will Need

Tools: Pencil, dust mask, craft saw, knife, sandpaper, paint and paintbrushes, brown shoe polish

1 small bottle gourd, cured and cleaned

1 broad candle

12-inch piece of velvet ribbon that matches the candle

1. Place the gourd on a soft surface, such as a foam pad or old pillow, and use the pencil to mark 2 parallel cutting lines on either side of the gourd's waist. One will be the bottom of the candle holder, and the other will be the top.

2. While wearing the dust mask, use the craft saw to remove the top and bottom from the gourd. Scrape away loose material from inside the gourd with the tip of the knife. Sand the cut edges and inside surfaces until they are smooth.

3. Paint the interior surfaces of the gourd, allow them to dry, and then apply a second coat.

4. If desired, paint the outside of the gourd. If you prefer a natural look, finish the gourd with two coats of brown shoe polish.

5. Set the candle holder on a level surface and insert a candle. If needed, use the knife to shape the bottom of the candle so that it sits firmly in place. Tie the velvet ribbon into a bow around the middle of the candle holder.

Make a Light Box from a Drawer

Barbara Pleasant

Providing ample light is often the most challenging aspect of growing your own seedlings. An inexpensive fluorescent light can do the job—provided you keep the bulb 2 to 3 inches from the seedlings' topmost leaves, and paint all nearby surfaces bright white to reflect every last light ray. This light box, made from an old drawer, can accommodate about a dozen seedlings at a time, and you can raise or lower the lights in keeping with the size of your plants. Between seed-starting seasons, simply take it apart for easy storage.

To make sure seedlings get as much light as they need, leave the lights on for about 14 hours a day (fluorescent lights give off very little heat, so don't worry about "cooking" your plants). If you like, add a timer to turn the lights on and off automatically. If the seed-starting mix dries out quickly (indoor air in late winter can often be quite dry), cover the box and lights with a sheet of clear plastic at night, after the lights are turned off. Be sure to remove it before turning the light back on, because it could pose a fire hazard.

You Will Need

Tools: Measuring tape, handsaw, drill, marking pencil, screwdriver

1 wood dresser drawer at least 19 inches wide

One 24-inch-long piece of poplar, ¼-inch thick and 4 inches wide

One 24-inch-long piece of poplar, ¼-inch thick and 3 inches wide

1 can of bright white spray enamel paint

Four 32 x 1 bolts with matching wing nuts

One 18-inch-long under-counter fluorescent light fixture

8 small ½-inch screw eyes

1. To make the frame for the lights, measure the exact width of the drawer between the outside edges. Cut the 4-inch-wide piece of poplar to this length to form the top piece. For the sides, cut the 3-inch-wide piece of poplar into two 12-inch-long pieces.

2. In a well-ventilated place or outdoors, paint the cut pieces and the inside of the drawer with white enamel paint.

3. Drill 2 holes in the lower section of each side piece for the bolts, with the holes about 2 inches apart and diagonal rather than straight across. Check to make sure the bolts will barely pass through the holes. Center one of the side pieces upright against the outside of the drawer, and use the pencil to mark

Continued →

where you should make matching holes in the side of the drawer. Drill holes through the pencil marks, and loosely attach the side piece to the drawer with bolts and wing nuts. Repeat on the other side.

4. Check to make sure the top piece fits correctly between the two side pieces. Follow the manufacturer's directions to attach the light fixture to the top of the light frame.

5. Unscrew the wing nuts to disassemble the sides. Use a small drill bit to make guide holes for the screw eyes in matching sets of two, which will support the lights at two different heights. Install one set of screw eyes 2 inches from the tops of the side pieces, and another set 2 inches below the first set.

6. Reassemble the side pieces, and firmly tighten the wing nuts. Slide the top into place at either of the two heights, so the ends rest on the screw eyes. Plant your seedlings in the drawer, and turn on the lights. Or, place seedlings started in small containers inside the drawer.

WEEDS

An Overview of Weeds

Jill Jesiolowski Cebenko and Deborah L. Martin

What makes a weed a weed? For some people, it's a plant out of place or a plant that competes with crops. Some weeds are poisonous or may cause allergies in livestock or people, while others may harbor insect pests and plant diseases.

But weeds can also be beneficial. Many weeds are excellent food sources for butterflies, bees, and the many beneficial insects that control pests. Handled correctly, they can make good green-manure crops. Some break up heavy soil and otherwise improve soil texture, and others bring up nutrients from the subsoil. Many birds and other wildlife depend on weedy areas for food and shelter. Some weeds are beautiful, some protect soils from erosion, some stabilize steep banks, and some are good food in their own right. As indicator plants, weeds can also tell you about your soil and growing conditions.

Weed Seeds

Soils contain millions of weed seeds. Researchers in England once sifted through the top few inches of soil on a hectare (2.47 acres) of land. They counted 1.33 million prostrate knotweed seeds, 1.73 million shepherd's purse seeds, 3.21 million chickweed seeds, and 16.6 million annual bluegrass seeds. This isn't surprising when you consider the number of seeds a single weed plant can produce. For example, curly dock sets an average of 29,500 seeds per plant, purslane sets 52,300, and redroot pigweed sets 117,400.

Not all seeds survive, of course, and many are eaten by birds and other animals. The ones that do survive don't germinate all at once. In many cases, environmental conditions inhibit sprouting and growth. The seed may be buried so deeply that the level of oxygen in surrounding soil is too low or the level of carbon dioxide too high to allow them to germinate. Temperature, light, day length, or moisture levels may not be

Continued ➔

right. Seeds can remain dormant for many years, waiting until conditions become right for germination (for example, being brought up to the surface when the soil is disturbed). Some seeds are "innately" dormant. They must go through the alternate freezing and thawing cycles of winter or some other process to break their dormancy.

Annual, Biennial, or Perennial?

Annual weeds live only one season. They usually germinate in spring, grow to maturity, produce seed in summer, and die in fall. They guarantee their survival by producing a significant number of seeds. Most weeds in your garden are annuals. They generally sprout quickly and grow rapidly. Common annuals include chickweed, knotweed, lamb's-quarters, pigweed, purslane, ragweed, and smartweed.

Winter annuals act almost like biennials (see below). They usually germinate in late summer and grow into a small rosette of leaves on the soil surface during their first year. The leaves may die back with heavy frosts, but they grow again in spring of the following year along with the flowering stalks. Flowering and seed production occur in spring or early summer, then the plant dies. Shepherd's purse is an example of a winter annual.

Biennials live for two seasons, producing leaves the first year—typically in the form of a low-lying *rosette* of leaves—and flowering and setting seed in the second year. Common biennials are burdock, mullein, Queen-Anne's-lace, and teasel.

Perennials have lifespans of 3 years or more. They produce seeds, and they also spread by their roots or bulbs. Many grow long, tenacious *taproots* that make them almost impossible to pull out. Some have long runners or underground roots that can send up new plants yards away from the parent plant. Common perennial weeds are bindweed, chicory, dandelion, goldenrod, and plantain.

Some of the most invasive and troublesome weeds are *woody perennials*. These include Japanese honeysuckle, kudzu, multiflora rose, and poison ivy. Birds enjoy the nutrient-rich seeds of woody perennials and are one of the main ways these noxious weeds spread—they ingest the seeds and deposit them elsewhere in their droppings. The stems of some of these plants can root wherever they touch the soil, so they multiply rapidly.

Grasses may seem like the worst weeds because they produce so many seeds and the plants are hard to uproot. Some perennial grasses, such as quackgrass, can produce new plants from underground stems yards away from the original plant. Most perennial grasses reproduce from rhizomes (creeping underground roots) as well as from seeds. Even some annual grasses, such as crabgrass, can send up new plants from stem joints that contact the soil.

7 Secrets of Weed Warriors

Vicki Mattern

Experience is often the best teacher, as every gardener who has ever let a weed go to seed knows. To find out the very best ways to prevent and eliminate garden weeds, the editors of *Organic Gardening* magazine asked readers for their most successful weed-beating strategies, tips, and techniques. Here are their top secrets:

1. **Timing is everything.** Don't think that you have to eradicate each and every weed the moment you see it. If weeds are too small, you may not be able to grasp them well enough to pull them out completely. On the other hand, waiting until weeds mature to control them isn't effective, either. By then, the wind may have carried their seeds throughout your garden, or their roots could have grown deeper than your cultivation tools will reach.

   Each weed has a certain size that's most responsive to your tug. When the soil is slightly moist and friable and the weed reaches that ideal in-between size, give a pull—it should come out with little resistance and without snapping off.

2. **Hot water works.** Many gardeners say that pouring boiling water on weeds is the most foolproof eradication method. Most weeds are killed within a day of receiving such treatment. Thistle and other tenacious types, however, may need to be scalded several times before they'll surrender.

3. **A little sodium may do the trick.** To keep weeds from growing between the paving stones of walkways or patios, *Organic Gardening* readers often pour ordinary table salt (sodium chloride) in the cracks. Weeds rarely grow back, they report.

   As an alternative to using salt, one reader sprinkled baking soda (sodium bicarbonate) directly on several weeds in his lawn. He found that the baking soda was more effective than hand pulling at killing such deep-rooted species as hairy cat's ears, dandelion, and broadleaf plantain.

   After experimenting with various application methods and amounts, he came up with the following recommendations:

   - Apply 1 teaspoon of baking soda per weed. Using less than a teaspoon won't kill the weed, but using more than that isn't necessary.
   - Sprinkle the baking soda over the entire weed. Placing the whole dosage on the center of the stem of each plant is less effective than covering the leaf surface.
   - Apply a second dose, if necessary. Although a single application of baking soda killed about 80 percent of the cat's ears plants, a second application was needed to control the plantain.

- Apply the baking soda at any time during the growing season. It seems to be equally effective whether applied in wet spring weather or during a summer drought.

Note: If you live in a dry climate where the soil may be naturally high in salt, be careful about using salt or baking soda to control weeds. Too much sodium could kill not only your weeds but also your garden plants.

4. **You can sprout them out . . .** If removing weeds one by one is too big a task in your garden, try managing their life cycle to suit your plans. In Europe, some gardeners and farmers spray beer on newly tilled land to stimulate the germination of weed seeds in spring. Two weeks later, the farmers till again, turning the weeds into instant green manure.

5. **. . . or crowd them out.** Speaking of green manure, be sure to try cover cropping, a classic technique for controlling weeds organically. One *Organic Gardening* reader moved to a new home that had no mulch materials for blocking weeds, so she planted a mixture of soybeans and buckwheat in vacant garden beds. The cover crops grew beautifully, shading out all but the most stalwart weeds. And because the soil was moist beneath the crops' leafy canopy, the surviving weeds came out with ease. As a bonus, the cover crops enriched the soil when she turned them under.

   Buckwheat is an especially appealing cover crop because it grows fast and matures in just 30 to 50 days. What's more, its white flowers attract pollinating bees to your garden. You might also consider one of the many types of vetch or clover, both of which help increase the soil's nitrogen content while they shade out weeds. Cover-crop seeds usually are sold at farm supply stores.

6. **When in doubt, mulch.** Mulch is a very effective way to control weeds, as many gardeners have known for years.

   Newspaper mulch makes a particularly good weed barrier. Here's what to do. When your plants are at least 2 or 3 inches tall (or just after you have transplanted them to the garden), surround them with a layer of newspaper, two sheets thick, and cover the paper with grass clippings. The clippings will keep the soil moist, while the paper prevents light from reaching weed seeds waiting to germinate. The newspaper and clippings will even yield benefits for your garden long after the weeds cease to be a threat. By fall, the paper will decompose and you'll be able to turn everything into the soil.

   If you'd rather leave those clippings right on the lawn to fertilize the grass, use a thicker layer of six to eight sheets of newspaper and anchor it in place with pine needles, bark chips, or another organic mulch.

7. **Action must follow planning.** Armed with the previous ideas, you might be tempted to lay back and contemplate which approach is best for your garden. Before you do, consider this caution sent by another reader: "Every year I plan to conquer the weeds in my garden, but that's about as far as I go. I'm sorry to say that my method of planning—without follow-through—has proven ineffective. I don't recommend it to amateurs."

10 Easy Ways to Beat Weeds

Vicki Mattern

A single weed has as many as 250,000 seeds. Though some seeds are viable for only a year, others can lie dormant for decades, just waiting for their chance to grow. Buried several inches deep, the lack of light keeps them from germinating. But bring weeds to the surface, and they'll germinate right along with your flower and vegetable seeds.

Even if you're diligent at hoeing and pulling weeds, more seeds arrive—by air, by water runoff, and in bird droppings. You may accidentally introduce weeds by bringing seeds in on your shoes, clothing, or equipment or in the soil surrounding the roots of container-grown stock.

If you had more weeds than seedlings last year or are already feeling defeated by the number of weeds choking out your favorite plants, don't worry! These surefire tips will help you keep down weed populations during the growing season:

1. **Know your enemy.** Before you can determine your best defense strategy against weeds, you need to know what you're up against. Some weeds, such as miner's lettuce, chickweed, purslane, and dozens of grasses, are shallow-rooted annuals. Others, such as dock, comfrey, thistles, and certain runner grasses, are deep-rooted perennials. The two types require different control methods. Arm yourself with a good field guide, then identify and inventory your weeds. After that, you can . . .

2. **Assault annual weeds when it's dry.** Wait for the weather to be hot and dry for several days, then attack young annual weeds with a rake, hoe, or trowel. That way, the drought-stressed weeds are sure to shrivel and die, even if your cultivation doesn't remove the entire root of the plant.

3. **Give perennial weeds a shower.** The long taproots of perennial weeds cannot be pulled out when the soil is dry. To remove these weeds, wait for wet soil—either from rainfall or from your hose. If the soil is wet and loose, even pesky thistles should come out with their roots intact—which means they won't grow back!

4. **Comb that grass right out of your beds.** If invasive grasses, such as Johnsongrass or bermudagrass, threaten your garden, use a pitchfork to "comb" your beds before you plant in spring, suggests an *Organic Gardening* reader. Work the

Continued ➔

soil until it's sufficiently loose for planting, then go over the entire area with a pitchfork, stabbing into the ground and levering it back toward the soil's surface. The tines of the fork will catch any buried grass roots, which you can then remove by hand. This technique has removed about 90 percent of the grasses from a reader's market garden in Texas.

5. **Become a mulching maniac.** Deprive weeds of the light they need by covering bare soil with a thick layer of grass clippings, shredded leaves, pine needles, or other organic mulch. Any survivors that do manage to penetrate the mulch usually are so weak that you can easily remove them by hand.

6. **Cook 'em.** If you've got a large-scale weed problem, bake the plants beneath a sheet of clear plastic. For best results, wet the soil before you cover it with the plastic. Leave the plastic in place for at least 3 weeks—ideally, when the weather is hot and sunny. This method is especially effective against cool-season weeds and annual grasses.

7. **Let lettuce help your peas.** Peas and other shallow-rooted crops can be damaged easily by cultivating the surrounding soil. That's why broad-leaved weeds can easily overtake them. So why not establish an edible, living mulch to fight the weeds and provide an extra early-season crop? Sow seeds of a fast-growing leaf lettuce thickly between young pea plants. The lettuce will outperform the weeds, and you can harvest the lettuce thinnings as you pick your peas.

8. **Squash pigweed.** If you're faced with a pugnacious patch of pigweed, fight back by planting a mixture of squash and buckwheat. The vigorous squash and quick-growing buckwheat will easily overtake the weeds. At the end of the season, harvest the squash, pull out the vines, and turn under the buckwheat. The buckwheat will add organic matter and nutrients to the soil for next year's crops.

9. **Berry your weeds.** Use strawberries to smother weeds! These perennial fruits spread by runners and are vigorous enough to overcome many weeds—even in light shade. In mild-winter areas, such as Zone 9, they'll grow (and hold off weeds) all year long. Try growing them as a groundcover beneath blueberries and roses.

10. **Till 'em two times...** In Maine's chilly Zone 5, organic market gardener Eliot Coleman uses a tiller to battle redroot pigweed, the seeds of which can remain viable in the soil for years. Coleman runs the tiller through his beds as early as possible in the spring to bring the weed seeds closer to soil's surface, where they can germinate. That's right: Coleman encourages the weed seeds to sprout! Then, a week or two later, he tills a second time to clear the area of the young weeds before he plants his vegetables.

Rules for Reading Weeds

Vicki Mattern

Before you draw any conclusions about what your weeds say about your soil, consider the following.

- Look for large populations of the same weed rather than just a few individual plants.
- Look for more than one type of "indicator weed." Two or more weeds that like the same conditions are stronger evidence that your soil provides those conditions.
- Consider the health of the weeds. Robust plants are good indicators; weeds that look pale or weak don't tell you much about your soil.
- Weeds that keep coming back year after year are especially good indicators of soil conditions. Their environment must be hospitable for them to survive (or reseed) from one year to the next.

Spring Ahead in Fall

Never allow weeds to set seed, or you'll face an even bigger weed problem next year. It pays to be especially vigilant in late summer to fall, when daylight-sensitive annual weeds mature and produce seeds before they are killed by frost. No matter how busy you are with the harvest, take the time to pull out those weeds *before* they set seed—or you'll be hoeing forever next spring.

Outsmart Lawn Dandelions

If you see dandelions in your lawn, it probably means that the surface soil has become too acidic due to a loss of calcium through the removal of grass clippings. Under these conditions, dandelions get a foothold because their long taproot can reach into the subsoil for calcium, while the short roots of lawn grasses cannot. With the grasses too weak to crowd out the dandelions, the resourceful weeds thrive.

What to do? First, contact your cooperative extension office and find out how to have a soil test taken. (It usually costs less than $10.) Then, if the soil test confirms your suspicions, dust your lawn with lime according to the recommendations on the test. In milder cases you can use compost to replace the calcium. Also, set your lawnmower to cut the grass 3½ inches high (no lower), and allow the clippings to remain on your lawn. By taking these simple steps, you'll deprive dandelions of their competitive advantage.

Weeds Can Be Good Guys, Too

You may find it hard to believe, but having a few weeds here and there is actually good. Weeds can attract and provide shelter for beneficial insects (those that eat the pesky insects that damage plants). Weeds can help protect gardens and especially lawns from disease attacks, too. Because many diseases attack particular plant species, having more than one species of grass in the lawn ensures that your entire lawn won't succumb to a single disease. And some weeds offer other benefits: For example, dandelions are edible, and white clover provides nutrients for the soil.

Guide to Weeds

Jill Jesiolowski Cebenko and Deborah L. Martin

Weeds in this section are listed alphabetically by common name within groups divided according to their growth habits. They are grouped into annuals, biennials, perennials, woody perennials, and grasses. Scientific names are also given.

Prevention and Control

Weeds must be controlled in gardens because they compete for light, water, and food with desired plants. It's most important to keep weeds down when crop plants are small. Later, however, when crops are well established, an understory of low-growing weeds usually doesn't harm the crops. Crops may even benefit if the weeds attract beneficial insects or make it harder for pests to find their food plants.

Whether or not you should try to control weeds in nearby areas around the garden depends on the situation. Weeds that produce windblown seeds and those that are spread by birds feeding on the fruit have the potential to spread the farthest. This means that preventing them from going to seed in nearby areas could help reduce the number of weeds falling on your garden. For common weed species, however, there are usually so many growing in the area that it would be impractical to try to control them. Also, because many weeds are important food plants for bees, butterflies, and other beneficial insects as well as birds and other wildlife, it might be more important to leave the weedy hedgerows and ditches undisturbed. Where a new, invasive species is showing up, controlling the weed as it appears can be an effective way to slow its spread.

Learning about the life cycles of weeds can help you manage them effectively and can stop you from unintentionally making a weed problem worse. For example, tilling up quackgrass only makes it multiply faster. In general, annuals are managed by preventing them from setting seeds, whereas managing perennials means you also need to remove or kill the roots. It may take 3 years or more to completely eradicate some woody perennials.

Because many garden weeds are most simply dealt with by hoeing or pulling them as early as possible before they flower, the hardest part can be to tell weed seedlings from crop seedlings. With experience you'll be able to recognize younger weeds. At first, however, you may want to sow seeds in rows (rather than broadcast them randomly over a bed) so that you can safely pull plants that grow between the rows. A trick that helps is sowing a few radish seeds in each row—these germinate quickly, marking the row before the intentionally planted crop and weeds come up.

PREVENTION

Soil conditions. Although many weeds seem to be able to grow anywhere, some thrive only in certain conditions. By altering the conditions, you can make it harder for the weeds to grow, while at the same time improving conditions for garden plants. Examples include remedying poor drainage, which would inhibit the growth of weeds that like wet conditions, or adding lime to correct a low soil pH, which would discourage weeds that like acidic soils. In heavy soils, weeds are difficult to pull; but if you add compost and turn in organic matter, the soil becomes lighter, and weeds are easier to pull when they do sprout up.

CULTURAL CONTROLS

Smother crops. Growing green-manure crops can be used to smother some types of weeds while also benefiting the soil. Sow the smother crop thickly, and turn it under before any weeds that might have sprouted have a chance to set seed. When using green manure to control weeds, it's better to turn under two or three crops in quick succession during the season than to leave the cover crop to grow longer.

Closely seeded garden crops, such as leaf lettuce and other leafy greens, can also smother weeds or prevent their germination by shading the soil. Interplanting tall crops, such as corn, with crops that run over the ground, such as squash, can also reduce the amount of light reaching the weeds.

BIOLOGICAL CONTROLS

Research into biological controls for weeds has resulted in economical, long-term control of various introduced weeds. Most such weed control programs involve finding insects that fed on the weeds in the region they originally came from. The insects are extensively tested to make sure that they don't eat any desirable plants, and then they're released to attack the target weed.

Biological control insects have been released in North America for purple loosestrife, tansy ragwort, spurges, St.-John's-wort, various thistles, and others. Some plant disease fungi have also been developed as biological controls. Government agencies usually release these controls to benefit a whole region; they aren't something a home gardener would buy. An exception to this would be several fungi that are being developed to control dandelions in lawns.

Continued ➔

PHYSICAL CONTROLS

Simply hoeing and pulling weeds are tried-and-true weed-control methods that most gardeners use. Many well-designed weeding tools are available to help make this task easier and more efficient. Most annual weeds, if pulled before they flower, can be left in the garden to mulch the soil or can be composted. Annuals that readily sprout roots from stem joints and most perennial weeds should be removed from the garden and allowed to dry thoroughly before being composted. Here are a few more ideas for physical controls:

Cultivation. Repeated cultivation can greatly reduce the number of weed seeds in the soil. Allow the weeds to germinate, then destroy them by tilling or cultivating the soil. Allow the weeds to germinate for another 2 weeks, then cultivate again. If you have time to allow several cycles of germination and cultivation before sowing garden plants, you can considerably reduce the number of weeds that come up later in the crop.

Mulches. With respect to managing weeds, mulches have several advantages. First, the soil under mulches stays moist and loose, so it's easier to pull any weeds that grow. The thicker the mulch is, the more it will shade the soil and smother germinating weed seedlings. A 2- to 4-inch layer is usually enough to control most annual weeds if applied early in the season. Make sure the mulch is free from weed seeds, however, so that it doesn't cause more weed problems. Shredded leaves, clean straw, compost, and other organic materials help suppress weeds as well as provide other benefits to garden plants.

Extremely dense, light-excluding materials—such as black plastic, landscape fabric, or thick layers of newspaper or cardboard—can be used to smother all vegetation under them. These are commonly used to kill sod or smother established patches of weeds so that the soil can be used for a garden the following season. The heavy mulches may be needed for several years to control extremely vigorous woody perennials.

Mowing. For annual weeds, periodically mowing or cutting off the tops so they can't set seed will eradicate them in 1 year because the roots die in fall. For perennials, close cutting or mowing at 2- to 4-week intervals can also eventually kill the plants, because the roots become exhausted from sending up shoots.

Applying heat. There are several ways to apply heat to weeds to kill them—but heat is more useful for weeds on driveways, patios, and sidewalks than in gardens because the heat can also kill the garden plants. Pouring boiling water on weeds is an effective control for seedlings growing in crevices in bricks and pavement. Soil solarization (described on page 337) can heat the soil enough to kill weed seeds in the top layer of soil. Handheld flamers and infrared weeders can also be used to control weeds.

HERBICIDES

Although home recipes using salt, vinegar, or other household substances can be used to kill weeds, they're also very harmful to other plants and organisms in the soil. Salt, for example, is highly soluble and moves through the soil, damaging roots of trees and other desirable plants. In the garden setting, there's little use for herbicidal products because of the risk of harming desirable plants. Two organic herbicides that have some limited uses are as follows:

Fatty acids. A commercial nontoxic herbicide (Safer's) is made from fatty acids, which are naturally occurring ingredients used in making soap. It kills the leaves of plants but not the roots; therefore, it's most effective on annual weeds and on seedlings of perennials. Because a fatty-acid spray can also kill garden seedlings, it's best used in hard-surfaced areas or in garden areas before seeds are sown. There's no residual effect, so seeds can be planted immediately after using the fatty acids.

Corn gluten meal. A substance in corn gluten meal (a byproduct of animal feed) has been found to suppress germination of seeds without affecting growing plants. Several products are available for use on lawns, where they can both prevent weed seeds from germinating and provide some nutrients such as nitrogen. Corn gluten meal can also be used in garden areas where transplants, not seeds, are being planted.

ANNUALS

Sow Thistle

Sonchus oleraceus

Range: Throughout the United States and southern Canada; particularly troublesome in coastal regions.

Description: Plants grow 1 to 6 feet (30.5 to 183 cm) tall. Stems are erect and branched and ooze a milky sap when cut. Leaves are alternate on the stem and more numerous toward the base of the plant. The largest leaves are deeply cut into irregular lobes on each side, with an arrow-shaped tip and toothed, spiny leaf margins. Flower heads are pale yellow and rounded and resemble dandelions. Seeds have tufts of long hairs that allow them to be carried on the wind. Blooms June to October.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Hoe or pull plants or apply a thick mulch to prevent germination and to smother seedlings. Watch waste places for blooming sow thistles, and mow them before seedheads begin to form.

Notes: Sow thistles are common in both cultivated and uncultivated areas with good light exposure. Perennial sow

thistle, a troublesome weed in northern areas, looks like annual sow thistle, but the leaf is less prickly, and the flower is a more vivid yellow. The perennial species spreads from both the rootstock and the seeds and must be dug up to be eradicated. Both sow thistles are a source of food for hoverflies and other beneficial insects.

Black Nightshade

Solanum nigrum

Range: Eastern half of the United States and southeastern Canada.

Description: Plants grow 1 to 2 feet (30.5 to 61 cm) tall. Plants are low and spreading and branch prolifically. Leaves are alternate on the stem and are wide at the base of the leaf and narrow at the tip, with wavy edges. The star-shaped, five-petaled flowers are white and grow in clusters. Small green berries turn black upon maturity and contain numerous seeds. Seeds are wrinkled, flattened, and a dull yellow to brown color. Blooms from July to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Nightshade is rarely present in large numbers, so it's effective to pull or hoe any plants that take root in the garden. Prompt removal is advisable because nightshade can host pests that attack other tomato-family crops, such as Colorado potato beetle, and the bacteria that cause blackleg of potato, which survives on nightshade roots.

Notes: Nightshade is especially common in disturbed soils.

Carpetweed

Mollugo verticillata

Range: Throughout the United States (except north-central areas) and southern Canada.

Description: Stems grow to 1 foot (30.5 cm) long. Plants are bright green and prostrate and spread outward from a central taproot. They branch profusely at the base, making a flat, carpetlike mat. Leaves are smooth and narrow and taper to a point. They grow in clusters of five or six leaves in whorls from stem joints. Two to five small, white, five-petaled flowers also grow from stem joints. Seed capsules are tiny and three-lobed and hold numerous orange-red, ridged seeds. Blooms from June to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Pull carpetweed immediately because it grows, flowers, and sets seeds rapidly. Hoeing it off just below the soil line is effective. Apply dense mulches to smother seedlings.

Notes: Carpetweed tolerates a wide range of soil conditions.

Catchweed Bedstraw, Cleavers

Galium aparine

Range: Throughout the United States and southern Canada.

Description: Stems grow from 8 to 60 inches (20.3 to 152 cm) long. They lie on the ground or over other plants and are jointed, slender, and tough, with four lengthwise ridges. Short, downward-pointing bristles grow along the ridges. Leaves are lance-shaped, with a central vein and sharp bristles on the top surface and edges; they grow in clusters of six to eight leaves in a whorl at each stem joint. Flowers are small and white with four lobes joined into a tube; they grow in groups of one to three, on stalks that arise from leaf axils. Seedpods are round and bristly and are divided into two chambers. Blooms from May to July.

Life Cycle: Annual, reproducing by bristly seeds that stick to passing animals and people.

Prevention and Control: Hoeing and pulling will eradicate bedstraw from the garden. When removing the weed, dig down to get all roots because it readily sprouts again. Apply dense mulches to smother seedlings. Remove seeds from shoes and socks after working in infested areas, such as along edges of fields and pastures.

Notes: Catchweed bedstraw prefers moist, rich soils with moderately good drainage. It's commonly found in soils that once formed creek or river beds, on the edges of woodlands, and in slightly shaded areas formed by hedgerows and fences. Flowering occurs fairly early in the season, so remove plants as soon as you notice them.

Common Chickweed

Stellaria media

Range: Throughout the United States and southern Canada.

Description: Stems usually grow 4 to 12 inches (10.2 to 30.5 cm) long, but they can reach up to 18 inches (45.7 cm) long. Plants are bright green and grow in a loose mat on the soil surface. Stems branch profusely from the central crown, which grows from a fibrous, shallow root system. Leaves are small and oval, are pointed at the tip, and are opposite each other on the stem. Flowers are white, with five split petals, giving the appearance of ten petals. Sepals are green and hairy and extend beyond the petals. Seed capsules are oval and hold many red-brown, ridged seeds. Blooms from early spring to early winter.

Life Cycle: Annual or winter annual, reproducing both by seeds and by rooting along stems. Typically sets seed in fall and can grow vigorously during winter in mild climates.

Prevention and Control: Pull or hoe plants before they set seed. Because stems root easily, remove plants from the garden, and allow them to dry in the sun before composting them. Use dense mulches to smother seedlings.

Continued →

Notes: Though this plant likes rich soil, it tolerates high acidity. It makes the most vigorous growth during cool weather when soil moisture is high and can serve as a protective groundcover over garden soils in areas with mild winters. Edible.

Common Cocklebur

Xanthium strumarium

Range: Throughout the United States and southern Canada (except in Quebec and northern New England).

Description: Plants grow 1 to 4 feet (30.5 to 122 cm) tall. Stems are erect, ridged, and hairy, some with reddish spots; stems are so branched that established plants look like a bush. Leaves are large, triangular to heart-shaped, and slightly lobed, with toothed edges. They're alternate on the stem and rough on both sides. Male flowers grow in short terminal spikes and drop soon after the pollen has been shed. The female flowers grow in clusters in leaf axils. Burs develop from the female flowers; they have two larger, sharp, incurved hooks at the top and are covered with hooked bristles, which attach to passing people or animals. Burs are light green, turning brown and woody as they mature. Blooms in August and September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Hoe or pull plants in the garden. Use dense mulches to smother seedlings. In fields, mow before the plants flower, repeating as needed during the season to prevent plants from flowering.

Notes: Cocklebur seedlings are poisonous to livestock. Cocklebur grows well in wet soils. Cocklebur can be confused with common burdock, but the former has elongated burs, whereas burdock has round burs.

Common Mallow

Malva neglecta

Range: Throughout the United States and southern Canada.

Description: Stems grow 4 to 12 inches (10.2 to 30.5 cm) long. They branch at the base, appearing nearly erect or spreading close to the ground. Leaves are wide, rounded, slightly hairy, and sometimes slightly lobed, with softly toothed edges and long, slender petioles. Flowers are white to pale purple, have five petals, and are borne singly or in clusters from leaf axils. Seedpods are round and flattened and split into many pie-shaped segments. Blooms from April to October.

Life Cycle: Annual or biennial, reproducing by seeds.

Prevention and Control: Pull or hoe plants in the garden. Apply dense mulches to smother seedlings. Mow or cut larger plants in nearby areas to prevent them from setting seed.

Notes: Common mallow will grow in a wide range of soil conditions.

Common Ragweed

Ambrosia artemisiifolia

Range: Eastern and north-central United States, and central and eastern Canada.

Description: Plants grow 1 to 3 feet (30.5 to 91.4 cm) tall. Stems are erect, unbranched or branched toward the top. Leaves are smooth, deeply lobed, and fernlike. They're sometimes opposite on the stem at the base of the plant, but they're more commonly alternate for the entire length of the stem. The flower heads are greenish spikes that grow at the tips of the branches and from the leaf axils. Seeds develop inside a brown woody husk with spines along the top. Blooms from July through September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Because ragweed is shallow-rooted and reproduces only by seed, hoeing and pulling are effective. Use dense mulches to smother seedlings. Mow nearby roadsides and other weedy spots before the plants bloom to prevent flower and seed formation.

Notes: Ragweed is a source of irritating pollen and is the most common cause of hay fever in fall. In some states and provinces, ragweed is considered a noxious weed and falls under weed-control ordinances. Ragweed grows in poor, dry soils but is adaptable to a wide range of conditions.

Corn Cockle

Agrostemma githago

Range: Throughout the United States and southern Canada.

Description: Plants grow 1 to 3 feet (30.5 to 91.4 cm) tall. Stems are erect, are covered with soft hairs, and bulge slightly at the leaf joints. Leaves are lance-shaped, hairy, and opposite on the stem. Flowers are purplish pink and 1 to 2 inches (2.5 to 5.1 cm) wide, with five petals that have dark veins; they're borne one per stem and have long, narrow, green sepals. Seed capsules are puffy, with the sepals at the top; they hold many small, black, spiny seeds. The stems grow from a shallow taproot. Blooms from May to September.

Life Cycle: Winter annual, reproducing by seeds. Usually germinates in fall and sends up flowerstalks the next spring.

Prevention and Control: Pull or hoe plants before seeds set. Apply thick mulches to smother seedlings. Seed is rarely viable for more than a year if it's buried to a depth of 6 to 8 inches (15.2 to 20.3 cm).

Notes: Seeds are poisonous. Livestock and poultry must be kept off fields with corn cockle.

Corn Spurry

Spergularia arvensis

Range: West coastal United States and Canada; most of eastern United States; also Colorado.

Description: Stems are 6 to 18 inches (15.2 to 45.7 cm) high and slender and branching. Leaves are threadlike, ½ to 1 inch (1.3 to 2.5 cm) long, with grooves on the underside; they're arranged in whorls on the stems. The small, white, five-petaled flowers are carried at the ends of stems, which bend down as the seedpods ripen. The seedpods are longer than the sepals and split into five sections. The seeds are dull black, circular, and flattened, with a pale narrow wing around the outer edge.

Life Cycle: Annual; flowers all summer; spreads by seeds.

Prevention and Control: Hoe or pull plants before seeds set. Use dense mulches to smother seedlings.

Notes: Corn spurry grows best in light, sandy soils or gravelly areas. The flowers are attractive to beneficial insects such as parasitic wasps (page 844), so a moderate number of corn spurry plants among taller vigorous crop plants can be desirable.

Devil's Beggar-Ticks

Bidens frondosa

Range: Throughout the United States and southern Canada.

Description: Plants grow from 2 to 5 feet (61 to 152 cm) tall. Stems are usually smooth and are almost square; they grow in groups from a shallow, branched taproot. Leaves are opposite on the stem and are divided in three or five leaflets with pointed tips and toothed edges. They may have short hairs on the undersides but are always smooth on the upper surfaces. Flower heads are yellow-orange, with five petal-like outer flowers on each head. The seed is long and wedge-shaped, with two barbed spikes at the top. Blooms from July to October.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Hoe or pull plants. Use dense mulches to smother seedlings. Mow or cut plants in nearby areas before they set seed.

Notes: Devil's beggar-ticks prefer rich, moist soil but will grow along roadsides, in waste places, and in damp areas. Animals may carry seeds into the garden. This weed can be an alternate host for the Mexican bean beetle (page 855).

Field Dodders

Cuscuta spp.

Range: Throughout the United States south of Vermont and the Great Lakes, with the exception of much of the Pacific Coast states. Also found in prairie provinces in southern Canada.

Description: Stems may reach 7 feet (2.1 m) long, but because they grow in tangled masses on the host plant, the height is variable. Stringlike, yellowish, pinkish, or orange stems emerge from the ground. Dodders lack leaves because they don't produce chlorophyll. Instead, they have tiny suckers that attach to host plants. Once attached, the stem breaks from the root. The small, white, five-lobed flowers are produced in loose, rounded clusters. The calyx is large relative to the petals. Seeds are numerous, fairly small, and yellow to reddish brown. Blooms from July to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Dodder seeds can be spread to gardens and fields mixed in small-seeded grains, with cover-crop seed or in hay used as mulch. If flowers haven't yet formed, immediately pull both the dodder and the host plant and compost them. If flowers have formed, pull both the dodder and the host plant and burn or dispose of them in the garbage. If necessary, solarize the soil for the summer months where dodder has been a serious problem. If you can't remove the host plant, continue to remove and destroy all visible dodder several times a season for up to 2 years. If dodder is mixed in with a cover crop, keep the area mowed for the season to make sure it doesn't set seed.

Notes: Field dodder is a parasite. It prefers open, dry sites.

Giant Ragweed

Ambrosia trifida

Range: Throughout the United States, with the exception of Pacific Coast areas, and into southern Canada from southwest Quebec to British Columbia.

Description: Plants can grow to 12 feet (3.7 m) tall, but are usually 2½ to 6 feet (76.2 to 183 cm) tall. Stems are erect branched toward the top, covered with coarse hair, and rough. Leaves are hairy and divided into three or five deep lobes, with a border of leaf tissue along each side of the petiole. Flowers are greenish and grow on spikes at the tip of stems and in the leaf axils at the top of the plant. Blooms from July to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Hoe or pull ragweed that appears in the garden. Apply dense mulches to smother seedlings. Frequently mow any ragweed that's growing in waste places to prevent the formation of flowers and seeds.

Notes: Ragweed is a source of irritating pollen and is the most common cause of hay fever in fall. In some states and provinces, ragweed must be controlled by law. Giant ragweed prefers moist soils but will grow in less ideal conditions. It's common in hedgerows and along the edges of fields and roadsides.

Continued →

Jimsonweed

Datura stramonium

Range: East, Midwest, Southwest, and along the Pacific Coast of the United States and southern Canada.

Descriptions: Plants may grow to 5 feet (1.5 m) tall. They're bushy with spreading leaves, which are oval to triangular in shape with toothed edges. Stems are sometimes slightly purple. Flowers are white to pink and are a deep, funnel shape. Seed capsules are distinctly spiny and have four lobes. Seeds are kidney-shaped, flattened, and slightly pitted. Blooms from June to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Pull and compost jimsonweed before seed capsules start to form; wear gloves when handling plants because they can cause skin irritation. Use dense mulches to smother seedlings.

Notes: Jimsonweed resembles eggplant and thrives in rich soil and full sun. It can harbor diseases and pests common to other tomato-family crops. The seeds are poisonous.

Lamb's-Quarters

Chenopodium album

Range: Throughout the United States and southern Canada.

Description: Plants grow 1 to 3 feet (30.5 to 91.4 cm) tailor more in rich soil. Stems are upright and branched, typically with grooves of lighter green or red running lengthwise. Leaves are egg-shaped or roughly triangular with toothed edges. They're alternate on the stems and generally wider on the bottom than the top of the plant. Green or reddish green, petal-less flowers grow in irregularly shaped spikes at the tops of branches. Blooms from early summer through fall.

Life Cycle: Annual, reproducing by seeds. In fall, very young plants can flower and set seed before frost.

Prevention and Control: Pull or hoe lamb's-quarters when they're young because they grow rapidly. In hot dry weather, pulled seedlings can be left in the garden as mulch. Otherwise, compost them. Use dense mulches to smother seedlings.

Notes: Lamb's-quarters with a reddish purple sheen can indicate that the soil is nitrogen-deficient. Young leaves are edible, raw or cooked.

Marshpepper Smartweed

Polygonum hydropiper

Range: Throughout southern Canada and the United States (except for southern Georgia and Florida).

Description: Plants are 6 inches to 2½ feet (15.2 to 76.2 cm) tall. Stems are prominently jointed, erect, smooth, and sometimes reddish. Leaves are alternate on the stem, narrow, lance-shaped, and pointed at the tips; they're smooth to slightly hairy. Petioles are small or absent. Flowers are small, four-lobed, and greenish white with pink edges; they grow in terminal spikes that droop in arches. The calyx, which sometimes has slightly reddish margins, protects the dull brown, lens-shaped or triangular fruit that contains a single seed. Blooms from June to November.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Hoe or pull the plants. Remove pulled plants from the garden to prevent re-rooting from the stem nodes; dry in the sun before composting. Improving drainage helps to discourage the growth of smartweed.

Notes: Marshpepper smartweed prefers moist or boggy areas and is usually found in ditches, along shorelines, or in other low, poorly drained soils. Birds like the fruit and spread it to new ground. Stems and leaves are edible (they have a peppery flavor).

Mayweed

Anthemis cotula

Range: Throughout the United States and southern Canada.

Description: Plants can reach 12 to 18 inches (30.5 to 45.7 cm) tall. The multi-branched stem is erect and either smooth or covered with soft hairs. Leaves are alternate on the stem, light yellowish green, and finely divided into narrow segments. They have a distinctly bad odor when crushed. Small, white ray flowers surround a center of yellow disk flowers. Blooms from May to September.

Life Cycle: Annual, reproducing by seeds. In some climates, mayweed is a winter annual, germinating in late fall, overwintering, and sending up flowerstalks the following spring.

Prevention and Control: Hoe or pull plants in the garden. Use dense mulches to smother seedlings. Mow or cut plants in nearby areas to prevent formation of seeds.

Notes: Common names for this plant include stinkweed, fetid chamomile, dog fennel, and stinking daisy, all referring to the highly unpleasant odor that the leaves give off. Despite these names, it's attractive to beneficial insects and provides them with pollen and nectar. It's adapted to a wide range of soil conditions.

Mile-a-Minute

Polygonum perfoliatum

Range: Southern New England, New York to Virginia, and west to Ohio; it's expected to spread over a wider eastern and southern range.

Description: Plants grow as a long, trailing vine, with a delicate, reddish stem bearing hooked barbs. Leaves are light green, alternate on the stems, and nearly perfectly triangular in

shape, with hooks on the undersides. Distinctive cup-shaped, leafy structures circle the stems at intervals; this is where the small, white flowers (and later the fruit) emerge. Fruit are metallic blue and segmented; there's one shiny black seed in each segment. The vine grows very rapidly into a thick wave of vegetation that covers and smothers other plants, including trees. It produces many seeds continuously from June to October.

Life Cycle: Tender annual, killed by the first frost. Birds (and possibly other animals) feeding on the berries may spread seed over long distances. The seeds are also spread along streams because they can remain afloat in water for days.

Prevention and Control: Pull plants before flowers form. This task is easier before the barbs harden on the stems and leaves, but it can be done later (wear thick gloves and protective clothing because the tough barbs can seriously scratch skin). Check frequently for emergence of new seedlings. Repeatedly mowing or trimming plants to prevent them from flowering and setting seed will eventually control them as the vines die over the winter.

Notes: A native plant from Asia, it has been spreading from the original introduction site in Pennsylvania since the 1930s. It prefers extremely wet soils and full sun, but it can survive on drier sites and in part shade; it colonizes fields, stream banks, roadsides, and natural areas.

Morning Glories

Ipomoea spp.

Range: *I. purpurea* grows in the eastern half of the United States and Pacific Coast areas; *I. hederacea* grows in the eastern half of the United States (except in the most northern states).

Description: Stems grow from a few feet up to 10 feet (3 m) long, are slightly hairy, and twine around plants and objects in their path. Leaves are alternate on the stems with smooth edges and obvious veins arising from the midrib. Leaves of tall morning glory (*I. purpurea*) are heart-shaped, whereas leaves of ivy-leaved morning glory (*I. hederacea*) are three-lobed. Flowers are trumpet-shaped and pink, blue, purple, or white. They normally grow in groups of three to five from each flowerstalk. Blooms from July to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Morning glories can become troublesome in warm regions. Pull every shoot in and around the garden, and allow the plant material to dry thoroughly to kill the vines before composting them. Use dense mulches to smother seedlings.

Notes: Watch for bird-sown morning glory vines growing in hedges and along fencerows. Don't let plants that spring up in nearby waste places flower or set seed.

Pennsylvania Smartweed

Polygonum pensylvanicum

Lady's Thumb

Polygonum persicaria

Range: *P. pensylvanicum* is found in eastern and central United States as far west as Wyoming, and in southeastern Canada; *P. persicaria* has a similar range, including the northern half of the western United States into southern Canada,

Description: Plants grow up to 3 feet (91.4 cm) tall. Stems are erect, somewhat tough, and swollen at the stem joints. Leaves are alternate on the stem and long and pointed at both ends, and many of them have a darker splotch in the middle. The leaf has a short petiole extending from a sheath that encircles the stem. As the plant matures, lower sheaths dry and fall off; on *P. pensylvanicum* these papery sheaths have bristles. Flowers are pink or purplish, borne on short spikes, and are densely packed. Seeds are shiny and black. Blooms from late May to October.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Pulling and hoeing are effective controls for these annual plants. Apply dense mulches to smother seedlings. Mow plants in ditches and roadsides to prevent them from setting seeds near your garden.

Notes: Pennsylvania smartweed can tolerate wet or compacted soils, shade, acidity, and low-nutrient levels. If it becomes a serious pest in the garden, it may indicate poor drainage or other problems with the soil. As the soil improves, smartweed populations will decrease.

Prickly Lettuce

Lactuca serriola

Range: Throughout the United States and southern Canada.

Description: Plants may grow to 5 feet (1.5 m) tall. Stems are pale green and spiny, especially toward the bottom; they ooze a bitter, milky sap when cut. Leaves are alternate on the stem and sometimes blue-green, with short spines along the wavy or toothed margins. They clasp the stem tightly and have two lobes that project beyond the attachment point. The taproot is thick and deep. Flowers are numerous, small, and yellow. Seeds have a white tuft of hair at the end that enables them to be blown in the wind. Blooms from July to September.

Life Cycle: Annual, winter annual, or biennial, reproducing by seeds. The wind carries the seeds. Can sprout from the crown if only the foliage is removed.

Prevention and Control: Hoe or pull plants as you see them, cutting below the crown before they set seed. Apply dense mulches to smother seedlings. Prickly lettuce is rarely present in large numbers on cultivated land, but it can be a problem in

Continued →

old pastures or neglected fields. Mow or cut before flowering and again every 2 to 3 weeks thereafter to deplete the plant's reserves.

Notes: Most commonly found on light soils with good drainage. Prickly lettuce is an excellent plant for attracting beneficial insects; therefore, it could be left undisturbed in surrounding areas. However, because it can carry some of the same diseases as cultivated lettuce, it may help to remove it in surrounding areas if disease has been a continuing problem.

Prickly Sida

Sida spinosa

Range: Throughout the eastern two-thirds of the United States.

Description: Plants are 8 to 38 inches (20.3 to 96.5 cm) tall. Stems are erect, hairy, and many-branched. Leaves are alternate on the stem and lance-shaped with toothed margins. Two spiny projections grow from the base of each stem joint below the leaf petiole. The light yellow, five-petaled flowers also grow on short stalks from the stem joints. The calyx of the flower encloses the bottom of the seedpod. This also has five sections, each topped by two sharp beaks and containing a single seed. The plants grow from a long taproot. Blooms from June to October.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Prickly sida is easy to pull when it's young and small (wear gloves to protect your skin from the spines). It grows a long, tenacious taproot early in the season, so the most effective control is cutting stems from the root with a very sharp hoe. Don't let plants flower and set seed in waste areas or along fence rows or roadsides.

Notes: Prickly sida thrives in the climate and soils of southern states.

Prostrate Knotweed

Polygonum aviculare

Range: Throughout the United States and southern Canada.

Description: Stems are 6 to 24 inches (15.2 to 61 cm) long and lie flat on the soil surface, forming wiry mats. Slender, ridged stems arise from thin taproots and branch in all directions; the joints of the stems have a papery covering. The stems may rise upward slightly at the flowering tips. Leaves are alternate on the stem, smooth-edged, and elongated, with somewhat pointed tips. Flowers are small and white or yellow and bloom where they join the stem. Seeds are dull brown and triangular. Blooms from midsummer to late fall.

Life cycle: Annual, reproducing by seeds.

Prevention and Control: Pulling when the plant is young is the best control. Hoeing is effective on older plants, as long as the crown of the plant just at or slightly below the soil surface is severed from the roots. If knotweed is a serious problem, apply a dense mulch to smother weeds, and add organic matter or dig deeply, turning in compost or aged manure to aerate soil.

Notes: Prostrate knotweed grows where soils are hard and compacted. It's more likely to reside in permanent pathways than in the garden beds. Eliminate it from these areas by aerating with a spading fork and then covering with a deep mulch.

Prostrate Pigweed

Amaranthus blitoides

Range: Throughout southern Canada and the United States except the southernmost areas of Texas, Florida, and California.

Description: Stems are 8 to 24 inches (203 to 61 cm) long. Pigweed branches from the base and at nodes along each stem, spreading over the ground in a low mat. The reddish stems are smooth and commonly erect at the growing tips. Leaves are small and oval. Flowers are inconspicuous, lack petals, and are clustered in clumps that feel prickly to the touch. Seeds are lens-shaped and shiny black. Blooms from July to October.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Smother seedlings with dense mulches. Hoe or pull plants. Because seeds are so plentiful and flowers so inconspicuous, be careful to remove plants early in the season. Don't leave pulled weeds in the walkways if the plants have flowers because the earliest seeds can mature on the pulled plants.

Notes: Prostrate pigweed prefers dry, sandy soils; however, it will grow in any garden soil that has good drainage.

Purslane

Portulaca oleracea

Range: Throughout the United States and southern Canada.

Description: Stems grow to 1½ feet (45.7 cm) long, are smooth and succulent, and branch to form dense mats on the soil surface. The stems are usually tinged with red. Leaves are alternate or almost opposite on the stems and are rounded to oval in shape with smooth edges. Leaves may grow in a cluster at the tip of stems. Flowers are pale yellow and small and grow singly. The calyxes are green and enclose the petals, forming seed capsules that contain numerous tiny seeds. Blooms from July to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings as they sprout. Purslane doesn't germinate until soils have warmed, so seedlings may germinate after the garden has been cultivated in spring. Pulling and hoeing are effective

controls. Pulled plants shouldn't be left in the garden because little bits of stem can take root.

Notes: Stems and leaves of purslane are edible, raw or cooked.

Redroot Pigweed

Amaranthus retroflexus

Range: Throughout the United States and southern Canada.

Description: Plants can grow to 6 feet (1.8 m) tall, but they're usually much shorter. Stems are slightly reddish, rough or hairy, upright, but sometimes branching at the top. Leaves are alternate on stems, dull green, and oval with pointed tips. Leaf edges are slightly wavy. Flower clusters look more like green bottle brushes than blooms; they grow in spikes. Seeds are shiny black or red-brown. The tough, deep taproot is distinctly red at the soil line. Blooms from July to October.

Life Cycle: Annual, reproducing by seeds. Plants germinating in spring grow 1 to 3 feet (30.5 to 91.4 cm) tall before blooming, but plants that germinate in late summer and early fall can produce seed when they've grown only a few inches. A single plant can produce thousands of seeds, which can remain viable in the soil for years.

Prevention and Control: Apply dense mulches to smother seedlings. Pull or hoe seedlings. Remove pulled plants from the garden and dry them in the sun before composting because they root easily. For severe infestations, cultivate the soil and leave it open for up to 2 weeks to allow seeds to germinate, then cultivate to kill the seedlings; repeat the cycle several times. Heavy infestations can also be choked out by growing cover crops.

Notes: Redroot pigweed grows in any garden soil.

Shepherd's Purse

Capsella bursa-pastoris

Range: Throughout the United States and southern Canada.

Description: Plants grow 8 to 18 inches (20.3 to 45.7 cm) tall. A basal rosette of lobed leaves commonly appears in late summer or fall, but it can also grow in spring or summer. After the rosette has overwintered or is well established in spring or summer, erect stems grow from the crown. Stems are branched and typically covered with tiny, grayish hairs. Leaves growing from the stems are smaller and narrower than those in the basal rosette. They clasp the stem and have slightly toothed edges with an overall arrow shape. Four-petaled white flowers grow in long stalks at the ends of branches. Seedpods develop at the ends of the long stalks and are triangular in shape. Blooms from March to November.

Life Cycle: Annual or winter annual, reproducing by seeds.

Prevention and Control: Use dense mulches to smother seedlings. Hoe or pull plants before they flower or set seed. Shepherd's purse roots easily, so remove pulled plants from the garden and compost them.

Notes: Shepherd's purse is present in almost all gardens, fields, and roadways. Its flowers are a rich source of nectar for beneficial insects; therefore, allow it to remain in waste areas and roadsides.

Spanish Needles

Bidens bipinnata

Range: Throughout the eastern United States south of upper New York state, and west to Kansas.

Description: Plants grow 1 to 3 feet (30.5 to 91.4 cm) tall. Plants have a square stem that's sometimes hairy. Leaves are opposite on the stem and are fernlike leaflets with toothed edges. Flower heads are carried singly on long, leafless branches, toward the top of the plant. Pale yellow ray flowers surround darker yellow disk flowers in the center of each flower head. The long, slender seeds have three or four barbed spikes at the ends. Blooms from August to October.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Hoe or pull plants. Watch waste places and areas along woods, walls, fences, and hedgerows for Spanish needles, and mow before flowers form.

Notes: Spanish needles grow in sandy or rocky soils, open fields, and slightly wooded areas. The barbed seeds stick to clothing and to the fur of passing animals, ensuring seed dispersal over a wide area.

Spotted Spurge

Euphorbia maculata

Range: Eastern two-thirds of the United States, and the Pacific Coast region north of central California; also areas in the eastern half of southern Canada.

Description: Plants are 1 to 2 feet (30.5 to 61 cm) long. The purplish, multi-branched stems form a mat that lies flat on the ground. Stems have milky sap. Leaves are hairy, opposite on the stem, and oval with serrated edges. There's a reddish area near the base of the leaf that gives the plant its name. Flowers are tiny and have petals fused together to form a cup; they're carried at the tops of branches on long stalks. The seed capsule is usually three-sided and contains small, pitted, triangular seeds. Blooms June to October.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Hoe or pull plants. Spotted spurge germinates only in warm soils; look for seedlings in late spring and early summer.

Continued →

Notes: Spotted spurge can grow well in slightly dry, gravelly, or sandy soils. It doesn't grow in shade; therefore, the dense canopy of an intensively planted garden bed helps inhibit growth of any spotted spurge that germinates later in the season.

Velvet Leaf

Abutilon theophrasti

Range: Throughout the United States except northern Maine, Michigan, Wisconsin, and the southeastern states.

Description: Plants grows 4 to 6 feet (1.2 to 1.8 m) tall. Stems are erect and covered with velvety hairs. Leaves are also covered with short, velvety hairs. They're alternate on the stem and heart-shaped with tapering, pointed tips. Flowers are borne on short stalks near the top of the plant. They're cream- to yellow-colored, about ¾ inch (19.1 mm) wide, with five yellow petals and many visible stamens around the taller pistils. Seedpods are 1 inch (2.5 cm) wide and cup-shaped, with stiff, prickly spikes around the edge; each pod contains as many as 15 prickly seeds. Blooms in midsummer, and seed sets in late summer to early fall.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Pull or hoe plants. Mow plants in nearby waste places or along fencerows before seeds form.

Notes: Velvet leaf prefers rich, somewhat sandy soils in warm climates. Because the plant is so distinctive and grows only from seed, it's easy to eliminate from the garden.

Wild Mustards

Brassica spp.

Range: Throughout the United States and southern Canada.

Description: Plants grow up to 2 feet (61 cm) tall, depending on the species. Stems are erect and branched near the top. Leaves toward the bottom of the plant are lobed or deeply toothed; they become smaller toward the top. Small, bright yellow, four-petaled flowers are loosely clustered at the ends of branches. Seedpods are long and cylindrical and develop quickly. Seeds are dark brown or black. Blooms from early summer to late fall.

Life Cycle: Annual or winter annual, reproducing by seeds.

Prevention and Control: Use dense mulches to smother seedlings. Hoe or pull plants before seeds form. Seeds remain viable for many years in the soil. Mow plants along roadsides and field edges before seeds form.

Notes: Mustard flowers are an excellent source of nectar for beneficial insects, so allowing mustard to bloom in nearby areas can be useful. To avoid spreading seeds, pull plants immediately around the garden before the lower (earliest) flowers start to form seedpods; thoroughly dry the pulled plants before composting them. Leaves are edible.

BIENNIALS

Common Burdock

Arctium minus

Range: Northern two-thirds of the United States; southern Canada.

Description: Plants grow from 1 to 5 feet (305 to 152 cm) tall. During the first year, the stems are short and hairy and grow from a crown, forming a dense rosette of large, somewhat fuzzy, heart-shaped leaves with noticeable veins. The second year, the stems are elongated, erect, and branched, and the leaves are alternate on the stem. The bottom leaves can be 1 foot (30.5 cm) or more long; leaves are smaller toward the tops of the stems. Flowers are small, reddish, surrounded by spiny bracts, and clustered. Seeds are round, spiny burs, about ½ inch (12.7 mm) wide. Blooms from July to October.

Life Cycle: Biennial, reproducing by seeds.

Prevention and Control: Pull or hoe seedlings and first-year plants. Dig up second-year plants, ensuring that as much of the large, deep taproot is removed as possible; burn any plants that have developing burs. Cut or mow down flowerstalks of burdock along roadsides and nearby areas before they set seed; repeated mowing will eventually kill established plants.

Notes: Burdock prefers fertile soil in undisturbed areas such as fence rows or unused farmland. Burs stick to anything, so seed is easily spread by animals and people.

Common Teasel

Dipsacus fullonum

Range: Eastern United States, from central Maine to North Carolina and westward in a narrow strip to Utah; northern Pacific coast south to central California.

Description: Plants may grow to 6 feet (1.8 m) tall. First-year plants grow in a rosette of narrow, scallop-margined, prominently veined, spiny leaves. Second-year plants grow tall, erect stems. Stems are sturdy, angled, and prickly and usually branch toward the top of the plant. The leaves are opposite along the stems and commonly form a bowl-like structure where their bases join around the stem. Leaves are narrow, toothed, and prickly at the edges and on the underside of the midrib. Flowers are white or purple with four petals and bloom in a large egg-shaped head that later becomes a prickly brown seedhead. Sharp, long bracts extend well beyond the central flower and become stiffly hooked at maturity. Blooms from July to October.

Life Cycle: Biennial, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Pull or dig plants in the garden, taking out as much of the taproot as possible. If necessary to control plants in other

areas, cut or mow before plants set seed, repeating until no more shoots appear.

Notes: Dried flower heads of teasel were once used to card wool. Today, the distinctive seedheads are used in dried flower arrangements.

Garlic Mustard

Alliaria petiolata

Range: From eastern Canada south to Virginia and west to Kansas and Nebraska.

Description: Mature plants reach 2 to 3½ feet (61 to 91.4 cm) tall. First-year plants form a low-growing rosette of leaves that remains green during winter. In the second year, erect, flowering stems form in early spring. Leaves are triangular to heart-shaped with toothed edges; they smell distinctly of garlic when crushed. Flowers are small, white, buttonlike, with four petals and are borne in clusters at the tops of stalks. Seedpods are short, narrow, and four-sided and stand erect from the plant; they contain shiny black seeds. Blooms in early spring, with seeds forming as early as mid-May; by late June most stems have dried up; however, the seedpods remain through summer. Seeds can remain viable for 5 years or more.

Life Cycle: Biennial, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings (seedlings appear in fall). Hoe or pull plants anytime, making sure you remove the whole root because the plant can sprout from root pieces. Mow larger plants very early in the year before they set seed. Check for new shoots in a couple of weeks and mow again, repeating until no more shoots appear.

Notes: Garlic mustard tolerates poor, dry soil but thrives and is invasive in shaded and moist sites. It's commonly seen along roadsides and edges of woods. In some areas, this plant smothers native wildflowers—such as hepatica, trilliums, and wild ginger—that complete their life cycle in spring. The whole plant is edible, raw or cooked.

Henbit, Dead Nettle

Lamium amplexicaule

Range: Throughout the United States and southern Canada (except for the Dakotas, Montana, and part of Utah).

Description: Plants grow 4 to 16 inches (10.2 to 40.6 cm) tall. Stems are four-sided, branching, and upright. They tend to root where the lower joints of the stem come in contact with the soil. Leaves are opposite on the stem, hairy, and round, with deeply scalloped edges. Flowers are small and pink or purplish, with two lips and a long, tubular neck (corolla); they grow in whorls where upper leaves attach to stems. Blooms from April to June and again in September.

Life Cycle: Biennial or winter annual, reproducing by seeds and by rooting stems.

Prevention and Control: Apply dense mulches to smother seedlings. Hoe or pull plants, making sure that all pieces of roots are removed. Look for henbit early in the season, and control it before it drops seeds in the garden or adjacent areas. Remove pulled plants from the garden to prevent them from re-rooting; allow them to dry in the sun before composting.

Notes: Henbit prefers good soils and high-moisture levels. It prospers in cool, moist weather and is most troublesome in early spring and fall.

Poison Hemlock

Conium maculatum

Range: Throughout the United States and southern Canada (except for the north-central states and Canadian prairies).

Description: Plants grow to 2 to 7 feet (61 to 213 cm) tall. First-year plants form a low-growing rosette of leaves. Second-year stems grow tall, erect and branched. The stems are ridged and typically spotted with small purple splotches. More leaves appear at the base than at the top of the stems. Leaves are compound and fernlike, with finely cut leaflets arranged along a central stalk; they're triangular in overall outline. The tiny white flowers appear in umbrella-shaped heads at the ends of branches. Fruit is small and round and divides down the center into two sections, each containing one seed. The plant has a long, white taproot. Blooms from June to September.

Life Cycle: Biennial, reproducing by seeds.

Prevention and Control: Wear gloves, long sleeves, and pants while handling this plant; all parts are poisonous and can cause skin irritation. Pull or dig the plants early in the season before seeds begin to form, taking as much of the deep taproot as possible. Dispose of the pulled plants by throwing them in the garbage or by burying them deeply. Infestations on cultivated ground are rare, although the plant sometimes migrates onto the edges of fields.

Notes: It's believed that Socrates was poisoned with a tea made from the poison hemlock plant. Whether the story is true or not, all parts of poison hemlock are fatally poisonous.

Queen-Anne's-Lace, Wild Carrot

Daucus carota

Range: Throughout the United States and southern Canada (except for areas in the north-central states and Canadian prairies).

Description: Plants grow to 3 feet (91.4 cm) tall. First-year plants grow in a rosette of leaves from a white, fleshy taproot. Second-year plants grow tall, with erect, hollow stems that are

Continued ➔

ridged and hairy. Leaves are slightly hairy, compound, and fernlike. Leaves are alternate on the stems and attached to the stem by sheaths at their bases. Tiny white flowers form in flat, umbrella-shaped heads at the top of the plant. A single purplish flower commonly appears in the center of the flower head. As the flower heads mature, they cup inward. The light tan, seedlike fruits are ribbed and prickly. Blooms from June to September.

Life Cycle: Biennial, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Pull or dig plants in the garden, making sure you remove as much of the taproot as possible. Mow or cut down plants in other areas before seeds set, repeating until no more new shoots form. If the disease aster yellows has been a problem in garden plants, it may be helpful to control Queen-Anne's-lace in areas around the garden. Otherwise, it's such a valuable plant for attracting beneficial insects that it would be better to leave as much of it growing in nearby areas as possible.

Notes: Queen-Anne's-lace provides pollen and nectar for parasitic flies and wasps, minute pirate bugs, lady beetles, and many other beneficial insects that feed on pests of garden plants. The plant is common in dry soil, along roadsides and edges of fields.

Tansy Ragwort

Senecio jacobaea

Range: Atlantic coast from Maine to Rhode Island; Maritime Provinces of Canada; Pacific coast from British Columbia to northern California.

Description: Plants grow to 4 feet (1.2 m) tall. First-year plants grow in a low rosette from a taproot. Second-year plants send up tall, erect stems. Stems are coarse and usually branch only at the top below the flowers. Leaves are deeply cut and lobed, with toothed edges. At the base of the plant the leaves may be hairy on the undersides. Upper leaves are alternate on the stem but clasp the stem. Flowers are round, bright yellow, and buttonlike and up to ½ inch (12.7 mm) across; they grow in wide clusters. Blooms from July to September.

Life Cycle: Biennial or winter annual, but can be a short-lived perennial. Reproduces by seeds and by root pieces.

Prevention and Control: Dig or pull plants in the garden, removing as much of the taproot as possible. In fields and waste places, mow early and often enough to prevent flowering and setting seed. In some western and eastern regions, watch for beneficial insects that have been released as a biological control for ragwort. These include the cinnabar moth, which has yellow-and-black-striped caterpillars that feed on the foliage, and a species of flea beetle and a large weevil, both of which have larvae that bore in the roots and kill the plants.

Notes: This plant prefers dry soil. It produces an alkaloid in the foliage that's toxic to horses and cattle.

White Campion, White Cockle

Silene alba

Range: Eastern and north-central United States; Pacific Northwest United States, south to the middle of California; southern Canada from coast to coast.

Description: Plants grow 1 to 2½ feet (30.5 to 76.2 cm) tall. Stems are hairy, sticky, erect, and somewhat branching with an open habit. Leaves grow on stems in opposite pairs. They're hairy, light green, up to 4 inches (10.2 cm) long, and narrow with pointed tips. Flowers are held on long stems and are white to pink and fragrant, with five, deeply notched petals. They have a green-striped, bulbous tube below the petals. The seed capsule is toothed at the top and contains many flat, round, gray, bumpy seeds. Blooms from June to August.

Life Cycle: Biennial or short-lived perennial, reproducing by seeds and rootstock.

Prevention and Control: Apply dense mulches to smother seedlings. Hoe or pull plants, ensuring that the entire root is dug out. Mow or cut down plants before they set seed. Repeat the mowing until no shoots appear, or apply a dense mulch for one growing season.

Notes: This plant likes rich, well-drained soil and is commonly found along roadsides and bordering fields. It's an attractive plant for hoverflies and other beneficial insects, so it should be left to bloom in waste areas.

PERENNIALS

Broadleaf Plantain

Plantago major

Range: Throughout the United States and southern Canada.

Description: Plants are 6 to 18 inches (15.2 to 45.7 cm) tall. Leaves grow in a flattened rosette of rounded, waxy, green leaves, 3 to 4 inches (7.6 to 10.2 cm) long. Leaves are thick and rough, with prominent parallel veins from the tip to the base. The leaf stems are stiff and wide and cup upward into a trough shape. Stems that carry flower and seed spikes are wiry and grow from the center of the rosette of leaves. Flowers are tiny and green, and seed capsules are brown or slightly purplish. They contain as many as 15 seeds each. Plantain can be much shorter and flatter in areas where it's mowed or trampled (such as in lawns). Blooms from May to September.

Life Cycle: Perennial, reproducing by seeds.

Prevention and Control: Dig or pull plants from gardens and lawns, ensuring that the entire root is removed. Where it is difficult to remove the root, repeatedly cut off the plant at the soil line until the root stops sprouting. Where plantain continues to invade lawns it is often a sign of compacted soil;

therefore, aerate the lawn and spread a thin layer of compost to increase organic matter.

Notes: Plantain thrives in dense, compacted soils and shaded areas.

Buckhorn Plantain

Plantago lanceolata

Range: Throughout the United States and southern Canada.

Description: Flowerstalks are 6 to 24 inches (15.2 to 61 cm) tall. Stems are wiry, erect, and leafless, bearing only the flowering spike. Leaves grow in a low rosette of narrow, lance-shaped, dull green leaves up to 1 foot (30.5 cm) long. Leaves narrow at the base and have three to five prominent veins that run lengthwise. The flower spikes are oval to elongate and are held considerably above the leaves. Flowers are tiny, greenish, and numerous and have distinctive long, yellowish or pale stamens that stick well out from the spike. Seed capsules grow in rows along the spike, and each contains two smooth seeds. Plants can be much shorter where they have been mowed or trampled. Blooms from May to October.

Life Cycle: Perennial, reproducing from seeds.

Prevention and Control: Dig or pull plants from gardens and lawns, ensuring that the entire root is removed. Where it's difficult to remove the root, repeatedly cut off the plant at the soil line until the root stops sprouting. If plantain continues to invade the lawn, the soil may be compacted, so aerate and increase organic matter.

Notes: Plantains prefer dense, compacted soil. Problems with plantain decrease as hardpan is broken up and aerated.

Canada Thistle

Cirsium arvense

Range: Northern United States and southern Canada from Quebec westward.

Description: Plants grow from 2 to 5 feet (61 to 152 cm) tall. The stem is thin and erect, with branches at the top. Leaves are 4 to 5 inches (10.2 to 12.7 cm) long, alternate on the stem, and deeply lobed with toothed, spiny edges. They're silvery and hairy on the underside. Flower heads are pink to purplish, are ¾ inch (19.1 mm) wide, and are borne in loose clusters at the top of the plant. Bracts beneath the flowers have weak bristles, but there are no spines on the stems bearing the flower heads. The seeds are flattened, ribbed, and oblong, with tufts of white hairs that allow them to be carried in the wind. Roots are deep, wide-spreading rhizomes. Blooms from July to October.

Life Cycle: Perennial, reproducing by creeping roots (rhizomes) and seeds. Seeds have a long period of viability, and roots sprout prolifically.

Prevention and Control: Wear thick gloves and pull or dig plants, removing every piece of root possible. Dry out root pieces in the sun before composting. After removing plants, sow a thickly planted cover crop to smother shoots and prevent seeds from germinating; apply a dense mulch to smother new shoots, or cut down new shoots monthly. Mow or cut nearby plants in field edges or waste areas before they flower; continue mowing monthly for several growing seasons to deplete roots. (This step may not kill plants but will prevent patches from spreading.) Apply dense mulches (cardboard, newspaper, plastic) for at least one and possibly up to three growing seasons to smother shoots. Corn gluten meal herbicides are effective at killing seeds before they emerge (but not shoots or roots). Sheep and goats will eat the thistles.

Notes: In some regions, biological control insects have been released to combat Canada thistle.

Chicory

Cichorium intybus

Range: Throughout the United States (except areas south of North Carolina and the Texas panhandle, as well as portions of north-central states); southern Canada from Nova Scotia to British Columbia.

Description: Plants grow from 1 to 6 feet (30.5 to 183 cm) tall. Stems are erect, branched, and hollow and ooze a milky juice when cut. Leaves at the base of the plant form a rosette of roughly lance-shaped leaves with deeply toothed to lobed edges. Leaves are alternate on the stem, smaller and less lobed than lower leaves; toward the top of the plant, they clasp the stem. Flowers are round and blue (occasionally white), with many petals and up to 1½ inches (38.1 mm) wide. Up to three flowers appear on each long stem arising from the uppermost leaves. Two rows of bristly bracts at the flower base are quite visible. Flowers close each evening. Plants have a deep taproot. Blooms from June to October.

Life Cycle: Perennial, reproducing from seeds and by spreading roots.

Prevention and Control: Pull or hoe plants, making sure to remove as much of the root as possible. Apply dense mulches to smother seedlings or shoots sprouting from roots. Repeatedly cut plants below the crown to eventually kill established roots. If it's necessary to control chicory in nearby areas, mow or cut plants before seeds form; otherwise, leave plants growing to attract beneficial insects.

Notes: Chicory prefers soil with a neutral to slightly alkaline pH and is most troublesome in limestone areas. It's most common along roadsides, fences, and unused land. It attracts beneficial insects. Roots are used as a coffee substitute or additive.

Continued

Coltsfoot

Tussilago farfara

Range: Northeastern United States as well as southeastern Canada; eastern areas west to Minnesota as well as eastern areas in Canadian prairies.

Description: Flowerstalks reach 6 inches (15.2 cm) tall and appear in early spring. They're erect, scaly, leafless, and somewhat woolly, with a purplish tinge. Leaves are heart-shaped, are 4 to 8 inches (10.2 to 20.3 cm) wide, and appear at the end of the flowering season. They have long petioles, and the undersides are covered with whitish hairs. Flowers are light yellow and up to 2 inches (5.1 cm) wide and resemble dandelions, with many narrow petals. Seeds have a tuft of hair that allows them to be spread by the wind. Blooms from April to May.

Life Cycle: Perennial, reproducing by seeds and roots.

Prevention and Control: Apply dense mulches to smother seedlings. Pull or dig plants, taking care to follow the spreading roots and dig them out entirely. Dry them in the sun before composting pulled plants. For serious infestations, apply dense mulches for a growing season to smother plants or mow plants every few weeks until roots stop sending up shoots.

Notes: Coltsfoot is adapted to a wide range of conditions and is commonly seen along roadsides and waste areas.

Common Milkweed

Asclepias syriaca

Range: Eastern half of United States (except for the Gulf Coast); southern Canada from New Brunswick to Saskatchewan.

Description: Plants grow 2 to 5 feet (61 to 153 cm) tall. Stems are upright, stout, fuzzy, and not branched. When cut, stems ooze a milky sap. Leaves are 4 to 8 inches (10.2 to 20.3 cm) long, opposite on the stem, broadly oblong and rounded, thick, and tough, with prominent veins; they're smooth on top, downy on the underside. Flowers are borne in large clusters from the upper leaves and stem tips. The star-shaped blooms are waxy, pinkish white to darkish pink and fragrant. Seedpods are large, teardrop-shaped, green, and spiny; they ripen into dry, grayish brown husks that split down one side to release seeds. Seeds are flat, brown, and oval and tipped with many feathery, silky white hairs. Plants have an extensive creeping root system (rhizomes). Blooms from June to August.

Life Cycle: Perennial, reproducing by seeds and by rhizomes.

Prevention and Control: It's usually sufficient to pull plants found in the garden, as long as underground rhizomes are also removed. Apply dense mulches to smother seedlings or shoots sprouting from roots. Don't let pods ripen on plants near your garden. Where the caterpillars of monarch butterflies are present, manage milkweed in nearby areas by cutting off flower heads before the pods start to ripen, and leave the leafy part of the plant for the caterpillars.

Notes: Common milkweed is found in old pastures, woods, roadsides, and gardens. Milkweed grows in many conditions but is most common in drier soils. It's the only food plant for the caterpillars of monarch butterflies.

Common Pokeweed

Phytolacca Americana

Range: Throughout the United States from Maine to Minnesota, and southward, including the area between Florida and the eastern two-thirds of Texas.

Description: Plants grow 3 to 9 feet (91.4 to 274 cm) tall. Stems are thick, upright, and reddish. The stem is usually branched near the top. Leaves are alternate on the stem and oval, getting smaller toward the top of the plant. They're smooth, with alternate veins from the central midrib. The flowers grow in narrow, drooping, 4- to 6-inch (10.2 to 15.2 cm)-long strands, arising from stalks opposite upper leaves. The tiny, white flowers have five petals. They drop quickly and are followed by drooping clusters of dark purple berries, each containing 10 seeds. Plants grow from a large taproot. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds.

Prevention and Control: Use dense mulches to smother seedlings. Using gloves, pull or dig young plants before the large root develops. Large plants must be cut below the crown with a sharp spade, and as much of the root must be removed as possible. To clear ground of pokeweed, cut off and remove each group of stems, then continue to cut or mow the area every few weeks until they stop sprouting. Alternatively, after cutting down established plants, cover the entire area with a dense mulch (newspaper, cardboard, or plastic) for a growing season.

Notes: Pokeweed likes deep, rich, well-drained soils, but it doesn't survive long in a garden that's regularly cultivated. The entire plant is poisonous, except for young shoots.

Common Yarrow

Achillea millefolium

Range: Throughout the United States (except areas in the Southwest) and southern Canada.

Description: Plants grow 1 to 2 feet (30.5 to 61 cm) tall. Stems are erect and usually simple but may branch toward the top. Stems may be smooth or slightly hairy. Leaves are delicate and feathery and give off an aromatic scent when crushed. They're covered with soft gray hairs and arise almost directly from the stem. Flowers are carried in flat, compound clusters and are usually white or yellow (rarely pinkish). Blooms from June to October.

Life Cycle: Perennial, reproducing by seeds and roots.

Prevention and Control: Pull plants in the garden before they set seed, making sure that all roots are removed. Apply dense mulches to smother seedlings or shoots growing from roots. It usually isn't necessary or desirable to remove yarrow from nearby areas because the plants provide pollen and nectar for beneficial insects, particularly hoverflies, lady beetles, and parasitic wasps.

Notes: Yarrow grows in various conditions but is particularly common in thin, poor soils. Flowers dry well for winter arrangements.

Common Yellow Wood Sorrel

Oxalis stricta

Range: Throughout the United States and southern Canada.

Description: Plants grow 4 to 18 inches (20.3 to 45.7 cm) tall. Young stems are generally erect but are thin and weak. As the plant grows, the stems branch in all directions and tend to spread low over the ground. Stems are light green and somewhat hairy. Leaves grow on long, thin petioles and are divided into three, heart-shaped leaflets with an obvious vein running down the center of each leaflet. Flowers are clear yellow with five petals. Seedpods are cylindrical and slightly hairy, with pointed tips. Seeds are tiny and are ejected quite a distance from the pod when it bursts. Blooms from May to October.

Life Cycle: Perennial, reproducing by seeds.

Prevention and Control: Hoe or pull plants before they set seed, removing all of the root. Plants can root readily from joints in the stem, so remove pulled plants from the garden and dry in the sun before composting. Use dense mulches to smother seedlings or shoots from pieces of root remaining in soil.

Notes: Wood sorrel is common with acid soil and in neglected areas, dry lawns, and bare soil. It grows quite well in shade.

Curly Dock

Rumex crispus

Range: Throughout the United States and southern Canada.

Description: Plants grow from 1 to 4 feet (30.5 to 122 cm) tall. A dense rosette of thick, 6- to 12-inch (15.2 to 30.5 cm)-long leaves grows first from a thick, branching taproot. Later, flowering stalks grow from the rosette; stems are hairless and ridged, with enlarged joints; stems turn reddish brown in fall. Leaves are lance-shaped, with curly or wavy margins. Leaves growing on the stems are alternate, with short petioles growing from a papery sheath just above each leaf joint. The flower head has many branches with small, narrow leaves interspersed among the flowers. The small, greenish flowers become reddish brown as they age. The seeds are shiny, brown, and triangular, with a papery, winged covering. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds.

Prevention and Control: Pull or dig plants, making sure that the entire large, branched taproot is dug out of the soil. Removing dock is easiest when it's young, before the taproot has had a chance to grow deep. Apply dense mulches to smother seedlings or shoots arising from root pieces.

Notes: Curly dock is tolerant of poor conditions, but it's most common in moist soils. It commonly grows along roadsides and ditches, at the edges of fields, and in waste places.

Dandelion

Taraxacum officinale

Range: Throughout most of the United States and southern Canada.

Description: Flowerstalks grow to 1 to 12 inches (2.5 to 15.2 cm) high. Plants grow a basal rosette of lobed or toothed leaves arising from a deep, fleshy taproot. When leaves or stems are cut, they ooze a milky sap. Flower buds are nestled into the leaf rosettes at first, then grow above the leaves. Flower heads are bright yellow, 1 to 2 inches (2.5 to 5.1 cm) across; the flowerstalks are hollow, smooth, and pale on the outside. Seeds have tufts of hairs that allow them to drift in the wind. Plants can grow and flower as flat, low rosettes where they're repeatedly mowed or trampled. Blooms from March to December.

Life Cycle: Perennial, reproducing by seeds and from root crowns.

Prevention and Control: Where dandelions aren't desired, dig or pull plants before the seeds set, removing as much of the taproot as possible. For lawns, use a sharp, forked dandelion cutter to sever the taproot as deeply as possible, disturbing the soil as little as possible. (The larger the opening in the soil, the more likely it is that weed seeds will germinate in the opening.) Persistent plants may require digging several times to remove new shoots developing from roots. Dandelions provide a vital source of early pollen for bees and many other beneficial insects that feed on garden pests; therefore, it's neither necessary nor desirable to eradicate them from nearby areas.

Notes: Dandelion flowers can be used to make wine, the leaves can be cooked or eaten fresh, and the roots can be roasted for a coffee substitute.

Field Bindweed

Convolvulus arvensis

Range: Throughout the United States (except for Florida and the extreme southern areas of Texas and the Southwest) and southern Canada.

Continued ➔

Description: Stems are long, twining vines growing 2 to 7 feet (61 to 213 cm) long. They're smooth and thin, and they lie prostrate on the ground or climb up vegetation and objects. Leaves are alternate, simple, and smooth-edged, and many of them flare into two lobes at the base. Flowers are trumpet-shaped with a wide, round mouth; they're white or pink and 1 inch (2.5 cm) wide. The dark seeds have a rough, pebbly texture. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds and creeping roots.

Prevention and Control: Bindweed is difficult to eradicate because roots can extend for many feet in the soil. Dig or pull plants, making sure that the entire root is removed. Don't let it remain in the garden long enough to gain a foothold. For severe infestations, apply a dense mulch (newspaper, cardboard, or plastic that's well weighted down) to the area and to a wide area around the infestation to control spreading roots; leave in place for the entire season. Mow or cut plants in waste areas to prevent seeds from forming.

Notes: Bindweed likes rich soil, good drainage, and bright light conditions.

Field Horsetail

Equisetum arvense

Range: Throughout the United States (except in the Southeast) and southern Canada.

Description: Plants grow up to 18 inches tall (45.7 cm). Stems are stiff, erect, hollow, jointed, and very tough. They're either vegetative (which means they don't produce flowers) or fertile (which means they produce flowers). Fertile stems appear first in spring. They aren't branched; they have prominent, swollen joints and what looks like small oval pinecones (the fruiting heads) at the tips. The stem dies back after the fruiting heads shed their spores. Later the vegetative stems appear; these have whorls of long, thin branches arising from each leaf joint. The roots are strong rhizomes that can grow many feet deep in moist soils.

Life Cycle: Perennial, reproducing by spores and by creeping roots.

Prevention and Control: Pull or dig plants, removing as much of the root as possible; this is a temporary measure because shoots eventually grow back from the pieces of root left in the soil. Repeated removal, combined with keeping the soil cultivated and open, discourages horsetail sufficiently for the season to allow garden crops to grow. Smothering plants with dense mulches (cardboard, newspaper, or plastic) can provide temporary control; however, shoots can eventually penetrate even asphalt surfaces. Where possible, for long-term prevention of horsetail invasions, dry out the site by improving drainage, and enrich the soil with compost and organic matter; make sure that the soil is well drained over winter.

Notes: Horsetail thrives in moist, sandy, or gravelly soil, especially along edges of woods and fields and in ditches.

Goldenrods

Solidago spp.

Range: Many species throughout the United States and southern Canada.

Description: Plants grow from 2 to 5 feet (61 to 152 cm) tall. Stems are generally solitary, but they may be clustered. Leaves are numerous and crowded, especially toward the middle to the top of the plant. They're narrow and lance-shaped and have prominent, parallel veins and sharply toothed margins. Leaf undersides may be slightly hairy. Basal leaves usually die and drop as the season progresses. The many-branched flower heads are carried at the top of stems. Flowers are yellow to yellow-green and bloom on long spikes that droop in graceful arcs. Blooms from July to October.

Life Cycle: Perennial, reproducing by seeds and creeping rhizomes.

Prevention and Control: To remove plants from the garden, hoe or dig plants, removing as much of the root as possible. It may be necessary to dig established roots several times throughout the season whenever new sprouts appear. Apply a dense mulch to smother seedlings or shoots. It usually isn't necessary or desirable to control goldenrod in nearby areas and roadsides because it's an important source of pollen and nectar for bees and many beneficial insects.

Notes: Goldenrod can grow in any type of soil, but it does require good light. It's an important source of pollen and nectar for honeybees and other beneficial insects, such as minute pirate bugs and hoverflies. Contrary to popular belief, goldenrod doesn't cause hay fever; that's because it isn't pollinated by spreading pollen in the wind.

Ground Ivy

Glechoma hederacea

Range: Throughout the eastern half of both the United States and southern Canada, except for Florida and southern Georgia.

Description: Stems grow 15 to 30 inches (38.1 to 76.2 cm) long, usually spreading along the ground. Stems are four-sided and branching and commonly root at the stem joints. Leaves are round or kidney-shaped, bright green, and opposite on the stem, and they have scalloped margins. Flowers are blue or purplish and grow from the point where the leaf meets the stem on upright branches. They're small and trumpet-shaped, with two lips. Blooms from April to July.

Life Cycle: Perennial, reproducing by seeds and creeping stems.

Prevention and Control: Hoe or pull plants, making sure to take all roots and connecting stems. Remove pulled plants from the garden and dry them in the sun to prevent stems from sprouting roots when they're composted. Apply dense mulches to smother seedlings and shoots developing from fragments of stems left in the garden or to smother dense patches on lawns.

Notes: Ground ivy, a mint relative, prefers rich soils that are somewhat moist. It grows well in shade and typically tries to form a groundcover under trees.

Heal-All

Prunella vulgaris

Range: Throughout the United States (except for regions in the north-central states) and southern Canada.

Description: Stems are up to 24 inches (61 cm) long; they're four-sided and can be erect or prostrate on the soil. Leaves are opposite on the stems, hairy when young, and smooth as they mature; they have smooth or slightly toothed margins and are spaced widely along the stems. Flower spikes are thick, grow at the tips of branches, and have a pair of visible bracts below them. The small, tube-shaped flowers have two lips and are blue, purple, or pink (rarely white) with green or purplish calyxes. Where plants are mowed or trampled, they grow into dense, prostrate mats. Blooms from May to October.

Life Cycle: Perennial, reproducing by seeds and runners (stolons) that root at the joints.

Prevention and Control: Apply dense mulches to smother seedlings and young plants. Dig or pull plants, removing all of the connected above-ground runners and roots. Remove pulled plants from the garden and allow them to dry in the sun to prevent stems from sprouting roots before composting them.

Notes: Heal-all thrives in moist areas and is common in lawns and along roadsides.

Hedge Bindweed

Convolvulus sepium

Range: Eastern and northwestern United States and southern Canada.

Description: Stems grow 3 to 10 feet (91.4 to 305 cm) long and trail on the ground or twine up plants and over objects. Stems are usually smooth, but they may be covered with small hairs. Leaves are alternate on the stem and arrow- or heart-shaped, with pointed tips and squared-off lobes at the base. Flowers are trumpet-shaped, white or pinkish, and 1 to 2 inches (2.5 to 5.1 cm) wide. Roots are very long and shallow. Blooms from June to August.

Life Cycle: Perennial, reproducing by seeds and creeping underground stems (rhizomes).

Prevention and Control: Removing this invasive plant from gardens requires persistence in pulling it every time a shoot appears. Pull out roots and shoots, remove the pulled plants from the garden, and dry them in the sun before composting them. To remove a large patch of bindweed, apply a dense mulch (cardboard, newspaper, or plastic that's well weighted down) to the affected area and to a wide border around it; leave the mulch for the entire growing season and watch for roots spreading from under the mulched area. Limiting the area of moist soil in the garden by using a drip irrigation system helps prevent bindweed roots from re-colonizing garden beds because dry soil deters them. To control bindweed in hedges, cut the stems near the ground to kill tops and prevent seeds from forming.

Notes: Hedge bindweed can climb nearby plants or fences, but without a support it will trail along the ground. It's quite invasive, and it will quickly cover the edges of roadways or fields, choking out less vigorous plants. Bindweed likes rich, moist soils and good light. It grows quickly in the cool conditions of spring and fall, and in coastal areas it may continue to grow all winter.

Hoary Vervain

Verbena stricta

Range: Midwest, the Great Plains, Texas, and along the Pacific coast in the United States.

Description: Plants grow 1 to 4 feet (30.5 to 122 cm) tall. Stems are erect and simple or branched toward the top, and they're covered with soft, white hairs. Leaves are opposite on the stem and oval, with toothed edges. They have a coating of soft, white hairs that makes them look almost downy. Flowers grow in slender, upright spikes of small purple, pink, or white blooms; flowers open in succession from the bottom to the top of the spike. Seeds are dark brown. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds and by creeping underground roots (rhizomes).

Prevention and Control: Apply a dense mulch to smother seedlings. Pull or dig plants in the garden, removing the whole root system. Remove pulled plants from the garden to prevent them from rooting again, and dry them in the sun before composting. Cut or mow plants in nearby areas before they flower.

Notes: Hoary vervain likes dry, gravelly soils and grows well where fertility is low. It's unlikely to infest garden areas that are well tended and have high levels of organic matter.

Horse Nettle

Solanum carolinense

Range: In the eastern half of the United States, in the West from Idaho and Arizona to California (except the state of Washington), and in southern Canada.

Continued →

Description: Plants grow 1 to 3 feet (30.5 to 91.4 cm) tall. Stems are stout, erect, and branched or unbranched, with yellowish spines. Leaves are up to 5 inches (12.7 cm) long, alternate on the stem, and oblong or oval, with wavy or lobed edges. The leaves also have prickly, yellow spines along the veins and the leaf stem. The flowers are star-shaped, 1 inch (2.5 cm) wide, and white, pale blue, or violet. They bloom in small clusters, and each flower has a green calyx with five sepals at its base. Numerous seeds develop within a round, yellow-orange berry, which is ½ inch (12.7 mm) wide; the berries wrinkle as they mature. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds and creeping underground roots (rhizomes).

Prevention and Control: Wearing gloves, pull or dig plants before they flower and dig up the entire root system; remove the plants from the garden and dry them in the sun before composting. Cut or mow nearby plants in fields and along roadsides before they flower; repeat mowing as new shoots appear. To clear a heavily infested area, dig plants and then apply a dense mulch (newspaper, cardboard, or plastic) to smother new shoots for the growing season.

Notes: Horse nettle grows best in sandy soil in full sun. It's poisonous.

Purple Loosestrife

Lythrum salicaria

Range: Northeastern United States to Virginia and Missouri and western Washington State; eastern Canada and southern British Columbia.

Description: Plants grow 2 to 4 feet (61 to 122 cm) tall. Stems are stout and erect. Like the leaves, they may be smooth or have small, downy hairs. Leaves are opposite each other on the stem or arise in three-leaved whorls that clasp the stem. They're smaller and more lance-shaped toward the top of the plant; leaves at the base are more heart-shaped. Flowers are a clear purple color and very showy. They have six petals, grow in slender, upright, tapering spikes that are wider at the base, and are interspersed with leafy bracts. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds.

Prevention and Control: Loosestrife—along with its entire root system (which isn't extensive)—must be dug out to be eliminated, preferably before plants flower. Apply a dense mulch to smother seedlings. Cut or mow established plants and continue to mow every few weeks until plants stop sending up shoots, or mulch with newspaper, cardboard, or plastic for a growing season. Where loosestrife continues to be a problem, improve the drainage of the site if possible.

Notes: Loosestrife can grow in a range of conditions, but it thrives in moist, swampy conditions. It's an invasive weed that has become a serious pest in wetlands, where it chokes out native plants needed to sustain wildlife. The seeds float and are readily carried by flowing water to new sites. Although once considered an ornamental, it's now recognized as a serious problem and shouldn't be planted.

St.-John's-Wort

Hypericum perforatum

Range: Throughout the eastern half of both the United States and southern Canada; also southern British Columbia and Pacific Northwest states.

Description: Plants grow 1 to 2 feet (30.5 to 61 cm) tall. Stems are smooth, erect and multibranched with a woody base. The numerous leaves are each 1 inch (2.5 cm) long, oblong, and dotted with tiny pinhole spots that let light through. They're opposite on the stem and attached directly to the stem. The stems carrying the blooms are quite leafy. Flowers have five yellow-orange petals with dark dots at the edges of the petals. The flowers are 1 inch (2.5 cm) wide and have noticeable, long stamens growing in three distinct groups. The seedpods are round with pointed tips and contain three chambers with numerous seeds. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds and creeping roots.

Prevention and Control: Apply a dense mulch to smother seedlings. Using gloves, pull or dig plants, removing the entire root. To clean a heavily infested area, cut or mow the plants and continue to mow every few weeks until the roots stop sprouting, or apply a dense mulch (cardboard, newspaper, or plastic).

Notes: St.-John's-wort prefers dry, gravelly, or sandy soils; it won't grow in damp areas. It contains a compound that irritates the mouths of livestock that graze on it. It can also cause an allergic reaction and severe burns on skin with exposure to sunlight. In some regions, insects that eat St.-John's-wort are being released as a biological control.

Sheep Sorrel

Rumex acetosella

Range: Throughout the United States and southern Canada.

Description: Plants grow up to 6 to 18 inches (15.2 to 45.7 cm) tall. Young plants form a rosette of leaves, which are 1 to 3 inches long (2.5 to 7.6 cm) and arrow-shaped. Thin, erect, flowering stems grow from the center of the rosette; they branch toward the top of the stem. Leaves growing from stems are narrower than those in the rosette and have two distinct basal lobes. Stems and flowerstalks are reddish. Small, red or yellowish flowers grow on branching, upright spikes. The fruit is shiny, triangular, and yellow or reddish brown. Plants have widely spreading root systems. Blooms from May to October.

Life Cycle: Perennial, reproducing by seeds and extensive creeping roots (rhizomes).

Prevention and Control: Apply a dense mulch to smother seedlings. Pull or dig plants, along with the roots. Remove plants from the garden to prevent them from rooting, and dry them in the sun before composting. Improve soil fertility and add lime to raise the soil pH, which inhibits the growth of sorrel.

Notes: Sorrel typically indicates poor fertility. It grows on acidic, shallow, dry, or gravelly ground.

Stinging Nettle

Urtica dioica

Range: Eastern half of the United States (except Florida), eastern Washington State, Idaho, Colorado, northern Texas, and southern Canada.

Description: Plants grow 2 to 6 feet (61 to 183 cm) tall. Stems are erect and ridged and covered with hairs that sting bare skin, leaving red welts. Leaves are also covered with stinging hairs; they're opposite on the stem, rough, dark green, oval to heart-shaped with coarsely toothed margins. Tiny green flowers bloom in clusters on drooping spikes originating from points where leaves meet the stem and at the tips of stems. Fruits are tiny, grayish brown, and lens-shaped. Blooms from June to September.

Life Cycle: Perennial, reproducing by seeds and creeping roots (rhizomes).

Prevention and Control: Wear boots, thick pants, and tough gloves, and use a sharp spade to dig stinging nettles. Follow the spreading roots through the soil and lift them. Let the plant dry in the sun before composting (continue to wear gloves when handling the wilted plant material). Cut or mow plants and continue to mow every few weeks when shoots reappear, or apply a dense mulch (cardboard, newspaper, or plastic) for a growing season.

Notes: The leaves are edible as steamed greens.

Tall Ironweed

Vernonia altissima

Range: Eastern half of the United States south of Vermont and New Hampshire.

Description: Plants may reach 10 feet (3.1 m) tall. Stems are smooth and branch widely toward the top. Leaves are alternate on the stem, lance-shaped with pointed tips, and up to 10 inches (25.4 cm) long, with small, pointed teeth at the margins. They usually point upward, rather than horizontally from the stem. Flowers are reddish purple and ½ inch (12.7 mm) wide; they grow in loose, open clusters. Green, sharply toothed, leaf-like structures enclose the base of the flower heads. Blooms from August to October.

Life Cycle: Perennial, reproducing by seeds and creeping roots (rhizomes).

Prevention and Control: Dig or pull plants, along with the roots. Mow or cut plants in the late summer before they set seeds. Apply dense mulch (cardboard, newspaper, or plastic) to smother seedlings or shoots developing from roots of plants that have been mowed down. Improve the drainage of garden soils to discourage tall ironweed.

Notes: Tall ironweed prefers very moist, rich soils. It's an attractive food plant for bumblebees, so you may not want to eradicate plants in areas near the garden.

Wild Garlic

Allium vineale

Range: Throughout the United States.

Description: Plants grow 1 to 3 feet (30.5 to 61 cm) tall. Stems are stiff and erect, with leaves growing only from the lower half. Leaves are hollow with a basal sheath that encircles the stem. In some areas, wild garlic will flower and set seed. The flower head is umbrella-shaped and made up of whitish green, pink, or purplish red flowers on a short stock; plants set seeds in early spring. The plant produces small, grain-sized, aerial bulblets on the top of the stem and larger bulblets underground toward the end of summer. Blooms from May to June.

Life Cycle: Perennial, reproducing from seeds, aerial bulblets, and bulbs.

Prevention and Control: Dig up every plant, removing as many underground bulbs as you can find. Cultivate regularly to control developing shoots; this is most effective in dry soil. If wild garlic is a serious problem, apply a dense mulch (newspaper, cardboard, or plastic) to heavily infested areas for an entire season, Improving the soil drainage helps discourage the growth of the weed.

Notes: Wild garlic tolerates almost any environment but it grows best in heavy, fertile soil. Leaves smell like garlic.

Yellow Rocket, Winter Cress

Barbarea vulgaris

Range: Northeastern United States south to Arkansas, areas in the north-central states, and Pacific Northwest; southeastern Canada.

Description: Plants grow 1 to 2 feet (30.5 to 61 cm) tall. During the first year, a rosette of leaves forms close to the ground. Leaves are glossy and lobed; the rounded terminal lobe is so large that lower lobes look more like smaller individual leaves than portions of the same leaf. In spring of the second season,

Continued →

stems grow from the crown. The stems are hairless and may be ridged. Leaves are alternate on the stems and lobed at the base; they become less lobed and shorter toward the top of the stem. Flowers are bright yellow, have four petals, and grow in loose clusters at the end of each branch. They're followed by 1-inch (2.5 cm)-long seedpods with tiny yellow seeds. Plants have a deep taproot. Blooms from April to August.

Life Cycle: Short-lived perennial, reproducing by seeds; in some areas it grows like a winter annual.

Prevention and Control: Hoe or pull plants, removing the deep taproot. Cut or mow heavily infested areas before plants set seed, repeating mowing every few weeks until they stop sending up shoots, or apply a dense mulch (newspaper, cardboard, or plastic) for the growing season. It may not be necessary or desirable to control rocket in nearby waste or weedy areas because it's an excellent source of food for bees and beneficial insects.

Notes: Rocket likes rich soils with good moisture levels and quickly colonizes newly cultivated areas. It provides some of the earliest pollen and nectar in spring for beneficial insects and bees. It's edible.

WOODY PERENNIALS

Japanese Honeysuckle

Lonicera japonica

Range: Eastern half of the United States north to Michigan.

Description: Plants grow up to 30 feet (9.1 m) long. Stems are woody and trail or climb over vegetation and objects. Stems lying on the soil surface sprout roots at the leaf joints. Leaves are opposite on the stem, slightly hairy, and oval. Paired, highly fragrant, and white, pink, or yellow flowers arise from each side of the leaf joints just above the leaf. The five petals form a long tube with two uneven lips. Berries are purplish black and shiny. Two or three seeds are enclosed in each berry. Blooms from June to July.

Life Cycle: Perennial, reproducing from seeds, trailing stems, and underground rhizomes.

Prevention and Control: Pull seedlings as soon as they appear. Dig deeply to remove established rhizomes and rooting stems; continue to watch for new shoots, and remove them as they appear. This job takes several seasons; honeysuckle is vigorous and spreads rapidly. To slow the spread of plants, cut or mow plants in uncultivated areas before they set fruit (which is spread by birds), and continue to mow periodically for several seasons, or pasture goats in the area.

Notes: Honeysuckle twines up fences or nearby trees, or if it doesn't have support, it trails along the ground. Berries are a favorite food of many seed-spreading birds. In the southern states, leaves remain on the plant all winter.

Kudzu

Pueraria lobata

Range: Southeastern half of the United States and mid-Atlantic states.

Description: Plants reach up to 60 feet (18.3 m) long in one season, smothering vegetation and growing over objects. When young, the stems of the vine are slightly hairy, but as they age, they become woody and smooth. Leaves are divided into three leaflets; they're usually lobed and alternate along the stem. Flowers are small, reddish purple, and grape-scented and resemble pea flowers; they're borne in clusters. The large, upright petal is bright yellow at the base. Seedpods grow up to 4 inches (10.2 cm) long and look like hairy pea pods. Kudzu grows from a large, deep, starchy, tuberous root. Blooms from late August to September.

Life Cycle: Perennial, reproducing mainly by runners and stems that root at the leaf joints; also may sometimes spread by seeds.

Prevention and Control: Cut vines and dig out as much of the deep roots as possible. Because each piece of root can sprout, continue to watch for shoots, cutting or digging them as they appear or mowing closely every month for two growing seasons. Apply a dense mulch (newspaper, cardboard, or plastic) for one or more growing seasons to smother shoots—it may take 2 to 3 years to eliminate established vines.

Notes: The branching stems of kudzu twine around upright supports or trail long distances across the ground.

Multiflora Rose

Rosa multiflora

Range: Throughout most of the United States except the Rocky Mountain, desert, and southeastern coastal plain areas; parts of eastern Canada.

Description: Plants grow to 10 feet (3.1 m) tall. Stiff thorns protect the stems. The deciduous leaves are compound, divided into seven to nine oval leaflets, with sharp-toothed edges; they're arranged along a central stalk with a single middle leaflet at the tip. Leaves are fuzzy on the undersides. The flowers are white or light pink, fragrant, and about ¾ inch (19.1 mm) wide; they grow in clusters. Flowers are followed by bright red, pea-sized hips that can persist on the canes until spring. Blooms from May to June.

Life Cycle: Perennial, reproducing by seeds and from cane tips that root where they touch the soil.

Prevention and Control: Dig out plants invading gardens, removing as much of the roots as possible (wear heavy gloves to handle the canes). To clear thickets of rose, cut stems at the soil line, then continue to mow at monthly intervals, or apply a

dense mulch (newspaper, cardboard, or plastic) for at least one growing season. Eliminating this rose may take several seasons.

Notes: A full-grown multiflora rose is a huge shrub, with long stems that stand erect for 4 to 5 feet (1.2 to 1.5 m) then arch back to the ground. The hips are an excellent source of vitamin C and are relished by birds, which help spread the seeds.

Poison Ivy

Toxicodendron radicans (Rhus radicans)

Range: Throughout the United States (except for Alaska and California) and southern Canada.

Description: Poison ivy grows either as a shrub or as a climbing vine. All parts of the plant contain an oil that causes painful and itchy skin blisters. Each leaf is made up of three leaflets, 2 to 4 inches (5.1 to 10.2 cm) long, with pointed tips borne on long petioles. Leaves may be hairy or shiny, with smooth or slightly toothed edges. Shape and characteristics of the leaves vary; however, the leaves do turn red in fall. Flowers grow in clusters and are tiny and yellow-green, with five petals. Flowers are followed by small, hard, dry, white or grayish white fruit. Blooms from late May to July.

Life Cycle: Perennial, reproducing by seeds and creeping roots that grow from joints in the lower stems.

Prevention and Control: Wear protective clothing (gloves, long-sleeved shirt, pants, and boots) when working around this plant. Dig out roots as soon as you notice the characteristic three leaflets. In fall, about a week after the first hard frost, look for the leaves turning reddish orange, and dig out the plants. Put pulled plants and roots into heavy plastic bags, then discard them in the garbage, or allow pulled plants and roots to dry in the sun, then bury them. Don't compost poison ivy, and don't burn it because it produces toxic smoke. Note that some people are extremely sensitive to poison ivy and shouldn't attempt to control it until winter when leaves have fallen from the stems. Cut stems off at ground level, then apply a dense mulch (newspaper, cardboard, or plastic) for at least one growing season.

Notes: The toxic oil can remain for years on tools that come in contact with this weed. If you come in contact with poison ivy, immediately wash your skin thoroughly with soap and lots of water for 15 minutes; wash clothing with strong detergent.

Poison Oak

Toxicodendron toxicarium (Rhus toxicodendron)

Range: Southeastern United States from New Jersey to Florida, west to Missouri, Oklahoma, and Texas; related species in California.

Description: Plants grow to 4 to 6 feet (1.2 to 1.8 m) tall. All parts of the plant contain an oil that causes painful and itchy skin blisters. Stems are slender and woody. Unlike poison ivy, poison oak doesn't grow roots from stem joints, nor is it a climber. Leaves have soft hairs and are divided into three leaflets. Leaflets are also hairy and are variously shaped. Many have deep teeth or lobes and are shaped like maple or oak leaves. Flowers grow in clusters and are small and whitish with five petals. Green to light tan berries form in fall. Blooms from May to June.

Life Cycle: Perennial, reproducing by seeds and underground roots.

Prevention and Control: Wear protective clothing (gloves, long-sleeved shirt, pants, and boots) when working around this plant. Dig out roots as soon as you notice them. Put pulled plants and roots into heavy plastic bags, then discard in the garbage, or allow pulled plants and roots to dry in the sun, then bury them. Don't compost poison oak, and don't burn it because it produces toxic smoke. Cut stems off at ground level, then apply a dense mulch (newspaper, cardboard, or plastic) for at least one growing season.

Notes: The toxic oil can remain for years on tools that come in contact with this weed. If you come in contact with poison oak, immediately wash your skin thoroughly with soap and lots of water for 15 minutes (contrary to myth, this won't cause the rash to spread); wash clothing with strong detergent.

GRASSES

Bermudagrass

Cynodon dactylon

Range: Southern two-thirds of the United States; hardy only south of Pennsylvania.

Description: Stalks grow up to 1⅓ feet (40.6 cm) tall, but the rest of the plant is prostrate and creeping, forming dense sod. Rooting stems (stolons) lie along the soil surface, branching, rooting, and carrying the wiry stems. Leaves are fine, narrow, short, and gray-green, with a fringe of hairs just above the sheath where they attach to the stem. The flower head is divided into three to seven 1- to 2-inch (2.5 to 5.1 cm)-long spikes that radiate from the ends of erect stalks. Two rows of deep orange, prickly seeds develop along each spike. Roots are thin, scaly rhizomes. Blooms from June to August.

Life Cycle: Perennial, reproducing by rhizomes, stolons, and seeds.

Prevention and Control: Pull or dig plants, removing all roots and stolons. Allow pulled plants to dry in the sun before composting. In gardens with heavy infestations, apply a dense mulch (newspaper, cardboard, or plastic) for a growing season. In southern areas, solarizing the soil for the hottest part of the season can kill the roots. On the northern edge of its range, fall plowing to expose roots to heavy frosts can kill the plant.

Continued ➔

Notes: Bermudagrass can be used as a lawn or pasture grass in dry, sandy soils. If lawn plants are creeping into gardens, establish a mowed strip between the lawn and the garden or install an edging strip as a barrier to keep bermudagrass in bounds.

Crabgrasses

Digitaria spp.

Range: Throughout the United States and southern Canada. Large crabgrass (*D. sanguinalis*) isn't found in North Dakota; smooth crabgrass (*D. ischaemum*) isn't found in southern Florida, west Texas, or parts of the Southwest.

Description: Plants grow 15 inches (38.1 cm) (smooth crabgrass) to 3 feet (91.4 cm) (large crabgrass) tall. Stems can be erect or spread on the ground. They can root from joints of the stem lying on the soil, so crabgrass commonly forms a dense mat. Leaves of large crabgrass are hairy, narrow (¼ inch [6.4 mm] wide), and elongated. Leaves of smooth crabgrass are smaller and smooth, with a blue to purplish cast. Crabgrass flower heads grow in terminal spikes on upright stems. Tiny hairs grow both from the areas where leaves arise from their sheaths and on the bracts below the florets. Blooms from July to September.

Life Cycle: Annual, reproducing by seeds or from roots growing from stem joints.

Prevention and Control: Pull or dig plants before they set seed, removing all stems and roots. In lawns, fertilize in early spring to promote the growth of desired grasses and decrease the openings in the turf that allow crabgrass seed to germinate. Corn gluten meal herbicides can be used on lawns to stop crabgrass seeds from germinating (this has no effect on growing grasses). Repeated mowing only encourages crabgrass to grow in a spreading mat; because they can continue to flower and set seed, mowing isn't a control method.

Notes: Crabgrass is most common in dry and sandy soils, but it will grow in other conditions.

Foxtails

Setaria spp.

Range: Throughout United States and southern Canada.

Description: Green foxtail (*S. viridis*) grows 1 to 3 feet (30.5 to 91.4 cm) tall. It has erect or ascending stems that branch close to the base. Leaves are hairless but rough, and there's a fringe of hairs around the base of the leaf where it meets the stem. Flower heads are long, bristly, green spikes, 1 to 3 inches (2.5 to 7.6 cm) long with tips curving downward. Seeds are green and 1/16 inch (1.6 mm) long. Yellow foxtail (*S. glauca*) is shorter, growing 1 to 2 feet (30.5 to 61 cm) tall, and usually grows in clumps. The leaves have a few long hairs at the base where they attach to the stem. Its seeds are larger than green foxtail's and are yellowish. Foxtails may be shorter and more spreading in habit where they have been mowed or trampled. Blooms from June to September.

Life Cycle: Annual, reproducing by seeds.

Prevention and Control: Apply dense mulches to smother seedlings. Pull or dig plants in the garden as early as possible to ensure that no seeds have set. If renovating a field, mow before seeds form, and repeat if necessary; the following spring, cultivate several times before planting a cultivated crop. Several years of cultivating to control foxtail before it can set seed is usually enough to deplete the supply of viable seeds in the soil.

Notes: Foxtails tolerate a wide range of conditions and are commonly found along roadsides and in waste areas. They don't reproduce by underground stolons or rhizomes as many grasses do, so digging up scattered clumps is relatively easy.

Johnsongrass

Sorghum halepense

Range: Southern two-thirds of the United States and areas in Washington State and Oregon.

Description: Plants grow 1½ to 6 feet (45.7 to 183 cm) tall and have strong, erect stems. They look somewhat like slender corn plants. Leaves are 6 to 20 inches (15.2 to 50.8 cm) long and smooth, with a white vein down the center. Flowers are loose, upright, hairy, and purplish. The seeds are red-brown. Roots are fleshy, scaly rhizomes that may grow quite deep from established plants. Blooms from June to October.

Life Cycle: Perennial, reproducing by seeds and roots.

Prevention and Control: Dig Johnsongrass out of the garden, removing all roots. Apply a dense mulch (newspaper, cardboard, or plastic) for at least one growing season. The mulch may have to stay in place for two seasons. For serious infestations in fields, frequent mowing or close grazing is necessary to deplete the deepest growing roots.

Notes: Because established Johnsongrass clumps are very difficult to kill, remove small plants as soon as they're seen throughout the season.

Quackgrass, Couchgrass

Agropyron repens

Range: Throughout southern Canada and the United States except the southernmost states.

Description: Plants grow to 2 to 3 feet (61 to 91.4 cm) tall. Stems are smooth, with three to six joints. Leaves are narrow, with pointed tips; they're ribbed and rough to the touch on the upper surface, smooth on the undersides. A distinguishing characteristic of quackgrass is the pair of clawlike appendages

clasping the stem at the base of each leaf. Flowers are 2- to 6-inch (5.1 to 152 cm)-long spikes, with two opposite rows of tiny flowers arising from sharp and tiny bracts. The seeds are tiny, yellow-brown, and grain-shaped. Roots are tough, fibrous rhizomes, with many scaly joints. Blooms from late May to September.

Life Cycle: Cool-season perennial, reproducing by seeds and rhizomes.

Prevention and Control: Pull or dig plants from gardens, following along the lengths of roots to remove as much as possible. Dry pulled roots in the sun before composting. Continue to hoe or pull plants as shoots reappear. To clear infested areas, mow closely, then apply a dense mulch (newspaper, cardboard, or plastic) to smother shoots; or seed a smother crop (such as successive crops of buckwheat, followed by winter wheat or rye). Mulch heavily for several feet around all garden areas to prevent quackgrass from invading from nearby areas. Quackgrass roots are easiest to remove from deep, friable garden soils, so lighten heavy soils by digging in compost and green-manure crops.

Notes: Quackgrass is adapted to many soil conditions but prefers full sun; it's commonly seen in gardens, lawns, pastures, and neglected areas.

Weed Problems for Vegetable Gardeners

Fern Marshall Bradley

The secrets to success with weed control are simple: Stop weeds early, keep the soil covered as much as possible, learn how to fight persistent weeds, and never let weeds set seeds.

Do weeds have a positive aspect? Weeds do increase the diversity of a garden, and some produce deep roots that mine the subsoil for nutrients. However, the benefits of weeds usually don't outweigh the negatives: They compete with crops for water and nutrients, they host pest insects and diseases, and they restrict air movement. Perhaps the best way to view these plants as a benefit is to consider them an ever-present reason to enjoy a half hour in your garden, doing a little light weeding.

Sidestepping Weed Problems

Almost all gardeners lose a crop sooner or later because they fail to weed during a critical stage, or they till a weedy bed that they shouldn't, or they let weeds go to seed. These are easy mistakes to make, especially when your garden is just one of the many activities that fill your life.

The good news is there are strategies that help busy gardeners cope with weed problems, so that you never face the depressing task of trying to uncover young vegetable plants hidden under a jungle of weeds. You'll combine the following tactics:

- Limiting the food supply for weeds
- Pregerminating and killing weeds before you plant a crop
- Cultivating quickly and shallowly when weeds are small
- Mulching and planting cover crops to suppress weeds

CONTROL THE FOOD SOURCE

Standard soil preparation instructions for organic gardeners often read something like this: Spread 2 inches of compost over the surface of the bed and work it into the top few inches of soil. This technique creates a beautiful soil environment for extensive root growth. However, if your soil contains a large bank of weed seeds, it's also an invitation to weeds to sprout en masse because you're turning the soil—which brings weed seeds near the surface—and putting food (compost) within easy reach.

If you know that your soil is heavily stocked with weed seeds, try an alternate approach. Don't spread compost far and wide. Instead, disturb the soil surface as little as possible. If you plan to sow seeds, sow in narrow rows rather than wide rows or by broadcasting. Open a fairly deep furrow (2 or 3 inches), and fill it with compost to the depth at which you want to sow the seeds. Put your seeds in the furrow, and cover them with compost to soil level. This concentrates the nourishment right where the seedling roots can reach it and keeps it away from the perennial weed population. If you're planting transplants, dig the planting hole extra deep and wide, and mix in compost as you plant and refill the hole. (If the plant ends up on a little hill, that's fine—just mold a low berm around it to retain water. This also helps prevent weed competition by keeping the bed surface dry—all the water soaks in right around your plants.)

With this approach, you'll need to side-dress every few weeks as the crops grow because the limited supply of compost won't last too long. Or, once the soil is warm enough, spread compost on the soil surface and top it with a weed-seed-free mulch such as chopped leaves.

WEED FIRST, SOW LATER

Once the weed seed bank is at a more reasonable level in your garden, you can return to the soil preparation method of spreading compost and working it in. Be smart, though, and outwit weeds with a trick called the stale seedbed method. After you've prepared the bed, water it well, then let it sit for 2 weeks. A hearty crop of weed seedlings will sprout. At that point, you can kill the weeds by hoeing gently just below the soil surface or by using a flame weeder. Your goal is to disturb the soil as little as possible. After the hoed or flamed weed seedlings are dead, remove them from the soil surface and plant your crop seeds. Since you've already defeated the main flush of weed competition, your crop will have a much better chance to establish itself.

Continued →

CULTIVATE WHEN IT COUNTS

In spring, to encourage the soil to warm up and dry out, we deliberately leave the garden uncovered. What happens when soil is bare? Weed seeds germinate and rhizomes sprout, and many of them establish themselves more quickly than crop plants will. There's a critical window of competition between crops and weeds that starts about a week after a crop emerges and lasts about 1 month. During that month, if you don't handicap the weeds, chances are good that they'll outpace your crop, and the crop will never attain its full size and productivity.

Add compost to each planting site for transplants. A low berm around the transplant blocks water from running off, and that reduces weed seed germination.

Fast and Easy Cultivation

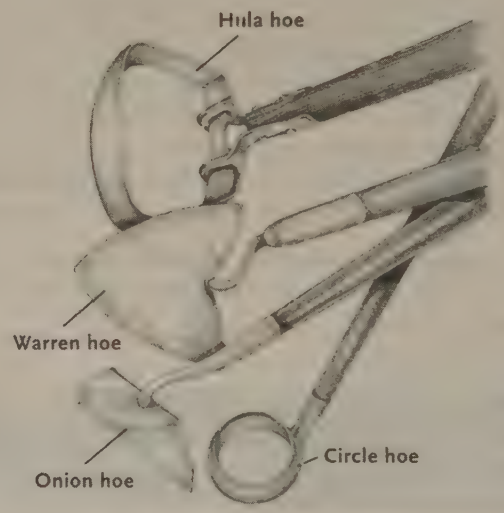
If you love to hand-weed, you'll enjoy early season weed control. Invest in a thick kneeling pad or a gardening stool to increase your comfort, and gently remove small weeds in crop rows and around seedlings. Be sure that the plants are dry before you weed (to avoid the risk of spreading disease spores), but to ease the job, weed when the soil is moist. If necessary, water the area the day before you weed.

If possible, weed in the morning on a sunny day, and leave the seedlings to wilt and die on the soil surface. Come back later or the following day and rake up the seedlings for your compost pile (seedlings left in the garden sometimes attract critters and diseases that feed on dying plant tissue, and then they may also spill over and attack your crop seedlings).

Take along an old screwdriver on your hand-weeding forays. It's handy for plunging into the soil to loosen up weeds with minimal disturbance to nearby crop seedlings.

Using a Weeding Tool. For weeding, try to find one long-handled hoe for clearing out weeds quickly, and also a short-handled tool for fine work closer to plant stems. Preferences vary when it comes to the design of a hoe blade, but it's worth it to buy a quality tool, whatever style you choose. And if back problems or arthritis in your hands bother you, investigate tool handle extensions that allow you to work without bending, and tools with padded handles that put less stress on your hands.

When you use a hoe or hand weeder, keep the blade parallel to the soil surface. Mentally picture a line half an inch below the soil surface, and pull your hoe blade gently down the bed following that line. Your goal is to cut through weed stems or pull weed roots loose from the soil without flipping or tossing soil. That's because when you disturb the surface soil, you expose more weed seeds to light and stimulate them to germinate.



Try a variety of hoes to see which works best for you.

Flame Weeding. A flame weeder can be a useful part of your weed control efforts. You can use a flame weeder to kill weeds between rows or hills of seedlings, but it takes precise technique to avoid singeing crop seedlings. Safety is always the most important considerations when using a flame weeder. Your goal is to pass the flame very lightly over the bed—the flame needs to come in contact with a weed seedling for just one-tenth of a second to kill it. You shouldn't see the weed seedlings turn black as you work; if you do, you're applying too much heat. The flame could be heating the soil, too, which damages soil organisms and crop roots. If you've done the job right, the weeds will begin to droop and wither about 24 hours after being flamed, and a day after that they will be dead.

Observe these precautions when you use a flame weeder:

- Always station a 5-gallon bucket of water or a hose nearby (be sure the water supply is turned on—use a breaker at the nozzle so you can release the flow in an instant).
- Never use a flame weeder on a garden bed that is covered with mulch.

About Organic Weed Killers

Insecticidal soap sprays that kill soft-bodied insects can also damage plant tissue, and garden product manufacturers have come up with herbicidal "soap sprays" as well—formulations of fatty acids that are strong enough to kill tender plants. Other organic herbicides have a vinegar base.

These herbicides work well for controlling weeds in the cracks along walkways and at the edges of patios, but they're not a good choice for the food garden. And of course, never use chemical herbicides in the vegetable garden. To safeguard your crops, your soil, and your health, stick with hoeing, mulching, and hand-weeding.

- Never use a flame weeder near any garden bed that is covered with dry mulch such as newspaper or wood chips.
- Never use a flame weeder near beds that contain dried-up plant residues.
- Never use a flame weeder on a windy day.

COVER THE SOIL

A good layer of mulch can very effectively prevent the return of weeds once you've prepared a garden bed (or after you've weeded). There are plenty of choices of mulch, from materials you have on hand—such as newspaper and grass clippings—to purchased plastic or organic mulches.

In some regions and circumstances, mulching the garden can lead to pest problems, providing hiding places for such undesirables as squash bugs and earwigs. And at the start of the season, leaving the soil uncovered to warm the soil is the most important consideration. But as soon as you can, put mulch in place. See the Mulch entry for details on mulch materials and how to manage mulch.

Another way to cover bare soil is to plant cover crops. These crops not only deny weeds the opportunity to grow but they also build soil structure, prevent erosion, and more. If you haven't been planting cover crops in your garden, start today.

Covering the soil with clear plastic to cause heat to build up and kill weed seeds is another way to fight weeds. This technique is called solarization and is discussed in detail on page 337.

KEEP AFTER SEED HEADS AND HOST PLANTS

Weed control is less critical at the height of the gardening season because most crops are large enough to withstand some weed competition. However, don't forget about weeds. Throughout the season, be on the watch for weeds that are going to seed and weeds that host serious vegetable crop diseases (particularly weeds in the cabbage and tomato families).

Weeds are prolific seed producers. A single pigweed plant can bear up to 250,000 seeds. Stopping deposits to the seed bank in the soil is one of the most effective ways to reduce future weed problems. Weeds also wreak havoc if they break out in a nasty disease that can spread to crop plants. For example, nightshade can suffer from late blight, a devastating fungal disease that can wipe out tomato and potato crops.

Summer is not always a fun time to weed, but, at the least, tour your garden every few days with a garbage bag and sharp garden clippers in hand. Cut flowerheads of weeds directly into the garbage bag (don't risk composting them, in case some seeds are already maturing in the flowerheads). You can come back later in the season when it's cooler to dig out the foliage and roots. If you spot weeds that are disease hosts, cut them off at ground level and stick them in the bag, too. (Never work around disease hosts when the garden is wet because disease spores spread easily in wet conditions.)

Battling Bigger Weeds

When weed seedlings escape your notice, they grow up to become full-size weeds. In most, but not all, cases it's a good idea to pull out such weeds, roots and all. But getting rid of big weeds can be tricky, depending on the type of roots they have. If a particular type of weed is fairly widespread in your garden, first pull up one to see what the roots are like.

Taproots. For weeds with a long, sturdy central root, such as dandelion, insert a dandelion fork or a narrow trowel vertically into the soil alongside the weed. Pull gently on the top and jab with the tool. You should feel the release as the root breaks or is cut well below the soil surface, and the root will pull freely from the soil. It's easiest to pull taprooted weeds a day or two after a soaking rain or watering.

Fibrous Roots. When the soil is moist, it can be fairly easy to pull out fibrous-rooted weeds simply by grasping the plant at the crown, where roots and topgrowth meet, and pulling upward. Use a hand fork to loosen the clump first if it resists—don't injure your hands or wrists by overpulling.

Bulbous Roots. Uproot these (wild onion, or onion grass, is an example) as you would fibrous-rooted weeds, but don't try to shake the soil free. The clump may include small bulblets that would fall free and then resprout in the bed. Carefully put the weeds, roots, and clinging soil into a hot compost pile to kill weed seeds. The heat will kill the bulbs, too. Otherwise, put these weeds into a discard pile or throw them out with household trash.

Rhizomes. If your problem weed has lots of long, somewhat fleshy roots that run horizontally at or below the soil surface,

Continued →

like those of many grasses, proceed with caution! These roots are specialized stems called rhizomes. Even a small piece of rhizome left behind in the soil when you pull the plant has the ability to resprout roots and leaves. Sometimes the best course of action with rhizomatous weeds is to repeatedly cut back the tops at ground level, leaving the roots undisturbed. It's a long process, but eventually you can starve out the roots and rhizomes by removing the weed tops.

Weed Emergencies

Sometimes weeds take over the garden much more quickly than you expect. Perhaps you had an extra busy week at work, or came down with a summer cold that kept you out of the garden entirely. If that particular week happens to be warm and wet, by the time you return to the garden, the weeds have taken over—everywhere. When a weed emergency like this happens, how do you get your garden back?

DECIDE WHAT TO SAVE

First, decide which crops are most worth saving. These may be crops such as melons or peppers that take the longest to produce. Or you may choose the vegetables you most like to eat. Weed out those beds. Next, put down mulch without delay. An ideal choice is newspaper topped by straw or chopped leaves, to ensure that you smother any weeds that resprout from roots left in the soil.

SACRIFICE TO SAVE

Next, take stock of how much time and energy you have to deal with the rest of your garden. If you can't save the whole garden, don't try. Choose a bed or two for sacrifice to the garden gods. In these beds, you'll quickly cut everything to ground level—weeds and crops—and then cover the bed while the plant material breaks down.

Before you bring in the lawn mower or string trimmer, though, check the beds for weeds that are going to seed. Use garden clippers to snip off all seed heads and discard them in plastic bags with your trash.

As you work, if you notice that a particular weed seems to dominate in a bed or throughout your garden, take time to identify it precisely. Refer to "Ten Weeds Worth Recognizing," next, for specific recommendations for bringing that weed under control, because you're bound to see it again in your garden in the future.

With weed seeds removed, cut all plants down to ground level. Cover the bed with black plastic, heavy cardboard, or an old wool (not synthetic) blanket, and weight down the edges. Later in the season, when you have time, you can uncover the bed and turn under the plant debris. Then wait a couple of weeks and if there's time left in the season, you can plant a fall crop.

Ten Weeds Worth Recognizing

In many gardens, one or two species of weeds are predominant. It's worth it to identify these dominant weeds to the species level so that you can plan the most effective approach for bringing them under control.

BERMUDAGRASS (*Cynodon dactylon*)

Range: Southern two-thirds of the United States, occasionally a problem farther north

Description: Also called wiregrass and devilgrass, bermudagrass grows fast and is a particular problem in Southeastern gardens. This perennial grass has a network of creeping stems with thin, gray-green or bluish green leaves.

Control Strategy: Dig out bermudagrass early and late in the season when you can search out and pull up its extensive roots without damaging crop roots. Let the plants dry in strong sun and then compost them. Solarizing a bed infested with bermudagrass will weaken the root system. Follow up by planting a cover crop to overwinter, and that will further reduce, although not eliminate, the problem. Mulching around crops helps, but bermudagrass often finds a way to pop up through mulch and then spread across the mulch surface.

BINDWEEDS (*Convolvulus* spp.)

Range: United States and Canada

Description: The pretty trumpetlike flowers and heart-shaped dark green leaves of bindweed, or wild morning glory, might tempt you to allow it to ramble in your garden, but don't be fooled. With roots that plunge down 10 feet and spreading vines, bindweed can be a nightmare in the garden.

Control Strategy: Pulling bindweed seedlings is okay because the full root will come up when you pull it. However, once a

plant has more than five leaves, the brittle roots will probably break as you pull them out, and pieces left behind will regrow. Mulching will help to weaken bindweed but won't control it fully. Solarizing and tilling aren't effective; flaming may weaken a stand over time.

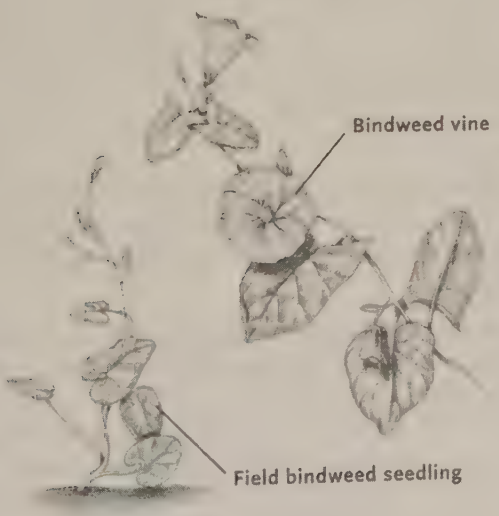
If only one bed or area of your garden is infested with bindweed, you can eradicate the weed by covering the area tightly with black plastic for 2 years.

Another approach is to weaken the stand first, then mulch to suppress regrowth. Let the bindweed grow until it's about to flower, then use a string trimmer to cut it back to ground level. New shoots will sprout. Let these grow for 3 weeks, then cut them back to the ground. After that, dig in the bed and pull out as many roots as you can. Dispose of these roots in the trash or burn them.

Next, cover the bed with cardboard or several thicknesses of wet newspaper, overlapping pieces well. Top that with a few inches of chopped leaves or other dense organic mulch. Check it occasionally. Bindweed shoots will find their way up through the mulch covering. Cut them off.

The following season, you can try cutting holes through this covering to set transplants in place. Renew the top mulch covering. Water the transplants directly at the base, and watch carefully for any bindweed shoots that try to grow out through these openings.

By the following season, the bindweed should have died out. This is more work-intensive than black plastic, but it's kinder to the soil.



CANADA THISTLE (*Cirsium arvense*)

Range: Northern half of United States, Canada

Description: Sharp spines along the edges of the crinkled, silvery leaves make this tough perennial weed hard to handle. Upright stems up to 5 feet tall sport pink to purple flowers from midsummer through fall.

Control Strategy: Wear thick gloves to cut back plant tops. Use a shovel or other tool to loosen roots before trying to pull out thistles. Let the roots dry thoroughly in the sun before composting. Never till this weed. Cutting back plant tops repeatedly will weaken the stand enough to allow successful gardening (but stay on the lookout for occasional shoots). When an area is seriously infested, though, try the mulching technique described for bindweed. If you don't take steps to weaken a strong thistle population, it could take over your entire garden.

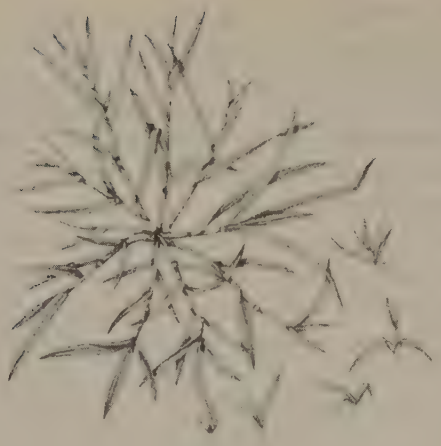
CRABGRASS (*Digitaria* spp.)

Range: United States and southern Canada

Description: This spreading annual grass sends out many thick, round stems from the base. Two common weed species are large crabgrass and smooth crabgrass. Large crabgrass leaves have white hairs along the edges. Smooth crabgrass leaves are smaller, with a purplish hue.

Control Strategy: Pull crabgrass by hand, removing all roots as well as stems. Don't compost plants if seeds have started to form. After clearing an area, mulch it well to prevent regrowth.

Continued ➔



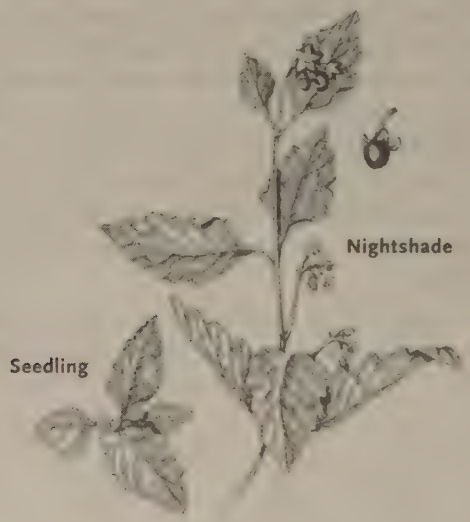
Crabgrass

NIGHTSHADES (*Solanum* spp.)

Range: Various species across the United States and Canada

Description: Nightshade rarely takes over a garden, but it's an important annual weed to control because it can host diseases and pests of the tomato family, including Colorado potato beetles. Nightshade has broad, wavy-edged leaves with narrow tips. The leaves are purplish underneath. White star-shaped flowers (they look very similar to pepper flowers) appear from midsummer to late summer. Later, flowers turn into green berries that mature to black.

Control Strategy: Hoe and hand-pull seedlings and young plants to minimize the chance for the weeds to become hosts for insect pests and diseases. Never allow nightshade plants to reach the stage of producing seeds. Mulch areas infested with nightshade seeds to suppress germination.



LAMB'S-QUARTERS (*Chenopodium album*)

Range: United States, Canada

Description: Lamb's-quarters is a pretty, bushy weed with slightly toothed, medium green leaves. Later in the season the stems become woody, and dead stems last into winter.

Control Strategy: It's easy to kill lamb's-quarters seedlings by hoeing and hand weeding, but watch for each new wave of plants. Young plants are edible, so you can add young, tender leaves to salads. Mulch beds once the soil is warm to prevent seeds from setting, and be mindful that plants produce multiple seed stalks; it doesn't help to cut back only the top of the plant. Don't compost any plants that have gone to flower.

Lamb's-quarters

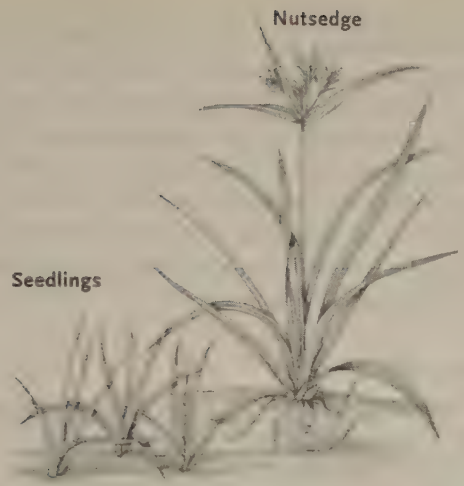
NUTSEDGES (*Cyperus* spp.)

Range: United States, Canada

Description: Sedges are grasslike plants with thick, yellowish green or dark green leaves that are V-shaped in cross section. The flowerheads are tufts of light-colored flower spikes at the top of the stems.

Control Strategy: The best strategy for controlling nutsedge is to pull out small plants, but only small plants, by hand. Once plants have more than six leaves, stop pulling them. Otherwise, as you pull the plants, you will knock loose tubers that have formed in the soil, and each tuber will produce a new plant. You can cut the plants back to soil level (they will resprout), and be sure to cut off tops if flowerstalks begin to appear.

Mulching and solarization won't provide thorough control (but they won't hurt). If nutsedge is limited to one part of your garden, try to plant a tall crop there because nutsedge won't grow as quickly when it's shaded.

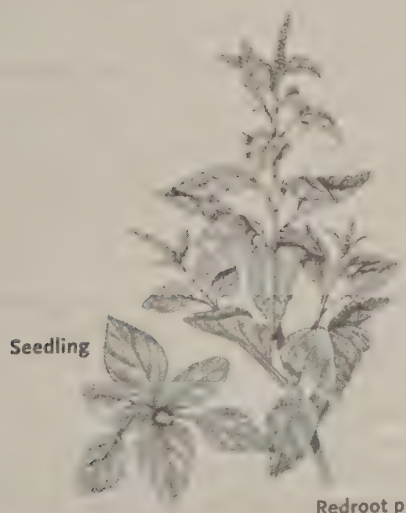


PIGWEEDS (*Amaranthus* spp.)

Range: United States, southern Canada

Description: These annuals begin to appear in gardens in late winter and continue germinating through summer. Redroot pigweed is the most common type, with oval leaves on upright, rough stems. Prostrate pigweed grows as dense, ground-hugging mats. It has a fleshy root that is hard to pull—pieces left behind in the soil will resprout. The flowers are hard to spot; they form in small clusters in the leaf axils.

Control Strategy: If pigweed grows past the seedling stage, uproot the plant as soon as you spot any flowers because these plants are highly prolific seed producers. Large pigweed plants develop a deep taproot, and you'll need to sever the taproot with a tool before you can pull out the plant. Don't compost plants that are in flower or bear seeds. Dry smaller plants well in the sun before composting, or they may rejuvenate in the pile and keep growing. Dense cover crops do a good job of smothering pigweed. Solarizing the soil will kill pigweed seeds in the top few inches of soil, which should give a year's reprieve from battling this weed.



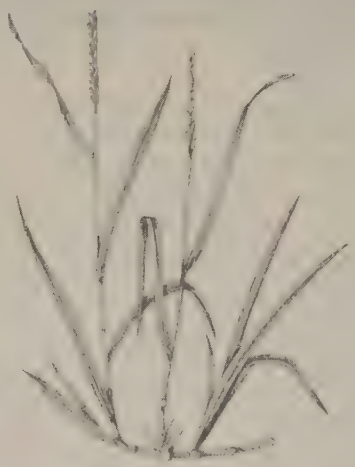
Redroot pigweed

QUACKGRASS (*Elytrigia repens*)

Range: United States, except for some areas of the Deep South and Southwest; Canada

Description: This perennial grass has upright stems with long, narrow leaves. Leaves feel rough on the upper surface but smooth on the underside. Also called couch grass and wheat grass, quackgrass produces long rhizomes that sprout fibrous roots at the nodes.

Control Strategy: Pull out individual plants, uprooting as much of the rhizomes as you can find. Bits of root will resprout, so work carefully. Let roots and rhizomes dry well before putting them in a compost pile. Never till a garden bed that's infested with quackgrass.



Quackgrass

SHEPHERD'S PURSE (*Capsella bursa-pastoris*)

Range: United States; Canada

Description: Seedlings of shepherd's purse resemble those of radishes and turnips, which isn't surprising because this annual weed belongs to the cabbage family. Shepherd's purse won't outcompete crops, but it's a weed to know and remove because it hosts some of the diseases that can infect cabbage and related crops, as well as the beet leafhopper, which transmits curly top virus.

Control Strategy: Cultivate to uproot young plants; when they dry, add them to the compost pile. When the soil warms, mulch the soil to prevent more plants from germinating.

Weeds and What to Do About Them

Roger Yepsen

While the automatic response of some homeowners is to wage an all-out herbicide attack, there are many less-drastic control measures—strategies that worked efficiently in the centuries before synthetics existed and that still do the job. And there are a few new wrinkles in weed control, as well.

Weeds aren't completely without redeeming values. Many of them produce food, including nectar and seeds, for wildlife (the monarch butterfly couldn't manage its well-known migration without weeds). You can get an idea of a weed's worth by taking the time to observe a forgotten patch of wild plants. It's likely to be a lively spot on every level—high and low, from afar and when viewed through a magnifying lens. Hawks hover overhead. Songbirds flit from one seedhead to another. Bees, butterflies, and many other insects flock to flowers no less attractive than those in carefully cultivated beds. Spiders spin their webs to harvest some of the bug life. Succulent plant growth is apt to be crawling with sap suckers of all sorts—not a sight to warm a gardener's heart, but these insects will help attract beneficial parasites and predators. There likely will be warm-blooded critters on the ground, as well.

The weeds you pull or mow can make an important contribution to the compost pile, so long as the temperature of your compost pile is high enough to inactivate seeds. And a healthy patch of weeds will even serve as a diagnostic tool, telling you something about the quality of your soil.

Compost Your Weeds

When you yank weeds or hoe them from the garden, the task will seem a little lighter if you see these unwanted plants as material for the compost pile. By only a slight stretch of the imagination, future crops will spring from the energy embodied in these unwanted visitors to the yard. You can even *encourage* certain weeds to grow for composting. Not every wild plant is a good candidate, but try permitting certain manageable annuals to leaf out—chickweed, lamb's-quarters, purslane, and ragweed are commonly seen choices. Just be sure to keep an eye on these weeds so that you harvest them for composting before they set seed. While a steaming-hot compost pile may inactivate weed seeds, it's best not to take a chance.

Pickle Your Weeds

Vinegar may preserve pickles, but it's devilishly tough on garden weeds. Studies by the USDA's Agricultural Research Service found that vinegar containing 15 to 20 percent acetic acid could knock out 95 to 100 percent of the weeds in its trail. But before you rush into your pantry for a bottle of apple or distilled vinegar, note that household vinegars typically run from just 5 to 8 percent. While this concentration may work well enough on younger weeds, you'll need to buy super-sour "horticultural vinegar" to get a near-complete kill. Check with local gardening centers. This natural herbicide is thought to work by breaking down cells in the leaves and desiccating the plant.

The vinegar is applied to foliage with an ordinary spray bottle. But do so with care. Horticultural vinegar can irritate the skin and eyes. It also is indiscriminate in what it kills, so make sure that the spray doesn't drift over to garden plants.

Annual Weed Bake-Off

You've felt the intensity of the midsummer sun on your back when gardening. Well, you can harness that energy to combat weeds, bacteria, fungi, and nematodes. All you need is a sheet of clear 1-mil plastic—and a good, long stretch of sunny weather. Also, keep in mind that while a bed is in the process of being *solarized* under that sheet, it will be out of commission for the 4 to 6 weeks that it takes the soil to cook. That may leave you enough time to plant early- and late-season crops.

1. Preceding the hottest 4 to 6 weeks of the growing season, groom the bed to be solarized, removing all garden waste and weeds.
2. Water the bed, soaking the soil well so that the sun's heat will penetrate deeper. (If the soil dries out in the weeks that follow, peel back the plastic in the early morning or evening, soak it again, then re-cover.)
3. Place the clear plastic over the bed. Use clear wrapping tape as necessary to seal any seams. Seal the perimeter of the area with a berm of soil.
4. You may need to leave the plastic on for the full 6 weeks, depending on your climate and also on how sunny the weather has been. Also, if this period has been unusually cloudy, temperatures under the plastic may be insufficient to do the job.

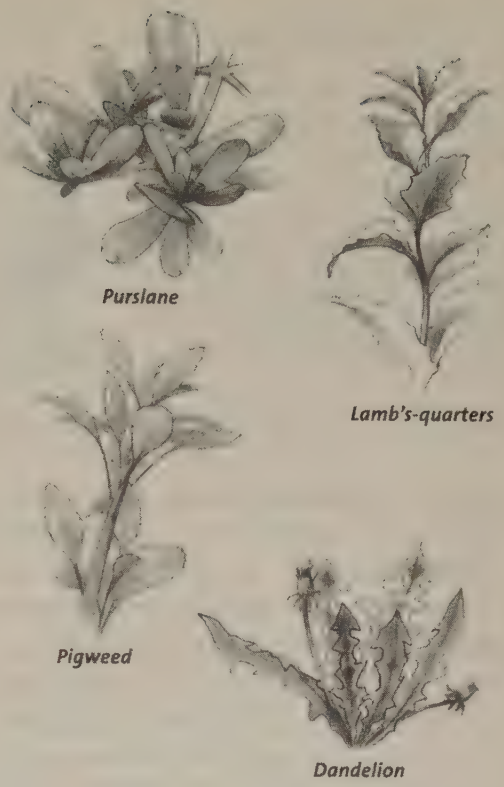
BRUSH HOGGING

There's an aggressive sound to the term "brush hogging," and this is a high-powered task as landscaping chores go. It involves taking on a patch of ground that has gone beyond the weedy stage and is host to shrubs and young trees. In many parts of the country, this is the natural fate of any area that's left to its own devices. Don't attempt to tame the woody stuff with your lawn mower. Instead, buy or rent a brush hog—either a dedicated walk-behind machine, or a self-powered unit that is towed behind a good-size lawn tractor. Some hogs can handle sapling trunks up to 2 inches in diameter.

Eat Your Weeds

A number of all-too-familiar garden weeds can be eaten fresh, steamed, or sautéed. That continues to be a tradition along the Mediterranean, with families going out to forage each spring. In the United States, we seem to have lost the knack, even though there's no shortage of wild edibles. You may find yourself fond enough of certain weeds that you dedicate a part of the garden to them, allowing your favorites to go to seed for the next year's crop. Try sautéing wild greens with garlic in olive oil. Add them to bean-and-pasta soup. Tuck them into calzones or layer them in lasagna.

- Purslane (*Portulaca oleracea*). A bright-colored variety, 'Goldberg,' is marketed for its hue and its more generous size, but the wild version is also fine, holding up well with cooking.
- Dandelion (*Taraxacum officinale*). This is perhaps the best-known wild green, and some people go off into the countryside in spring to harvest them. Get them young, before they become bitter. A traditional recipe from the Campagna region of southern Italy combines wild dandelion greens, sausage, and cannellini beans.
- Lamb's-quarters (*Chenopodium album*). The somewhat spinachlike young shoots can be used in salads and soups.
- Pigweed (*Amaranthus hybridus*). A relative of the amaranth you see in seed catalogs, this wild cousin offers leaves that are good steamed.
- Garlic mustard (*Alliaria petiolata*). This spring visitor catches your eye with its white flowers and your nose with its garlicky scent. Garlic mustard is an invasive nonnative species, but you can keep it in check by processing the leaves and taproots in a blender to make pesto, a novel idea suggested by Steve Brill in *The Wild Vegetarian Cookbook* (Harvard Common Press, 2002). Or simply toss a few leaves in a salad to give your greens an edge.
- Shepherd's purse (*Capsella bursa-pastoris*). The young leaves of this common weed are mild enough to use in salads. Collect the heart-shaped seeds for use as a peppery addition to soups.



KNOW WHAT YOU'RE PICKING

Before taking advantage of this no-plant, no-till, no-mulch harvest, take a few precautions. First, be familiar with what you're about to put on your plate. Educate yourself with a field guide or accompany a knowledgeable forager. Second, avoid plants that may have been sprayed with an herbicide, particularly along roadsides. Third, be cautious about having children seeing you forage, or they may do the same on their own—and some weeds, wild berries, and fungi are poisonous.

Weed Barriers for Walkways

There is no one perfect way to banish weeds from garden paths, except perhaps for laying down blacktop, and even paving can give way to certain aggressive growers. Most of us would prefer something soft and yielding underfoot, at any rate. A layer of mulch looks good, breaks down into a valuable soil amendment over time, and allows water to quickly perc through. But it won't be impervious to weeds, requiring a second out-of-sight layer to squelch them. Here are a few choices.

- Newspaper is free, if a bit lumpy. And unless you keep it well covered, it can be unsightly and—worse still—become airborne in a strong wind.
- A roll of plastic or landscape fabric goes down quickly, but it may not hold up more than one season and is not biodegradable.

Continued ➔

A Bouquet of Weeds

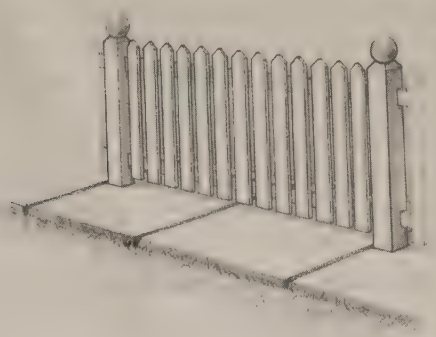
What could be easier than amassing a bouquet of roadside weeds? Focus less on brilliant blossoms than on texture and movement, and you'll find yourself appreciating all sorts of grasses, stems, and seedpods that once escaped your notice. Just make sure you check with landowners before harvesting what you *assume* to be up for grabs—you might not be the only one to treasure that patch of goldenrod or milkweed.

- A roll of brown kraft paper, available at office and art supply stores, also goes down in a jiffy, and it will biodegrade.
- Corrugated cardboard, recycled from large boxes, is stouter stuff than paper, and it also biodegrades.
- Roofing paper, with its coating of tar, is rugged stuff, and you can roll out more than one thickness for lasting effect.

If you've been unhappy with past efforts to tame garden paths, you might convert those vulnerable strips of soil to lawn. That's not a magical solution. First, you've got to establish a healthy patch of turf if the grass is to stand up to frequent foot traffic. That requires watering as needed and cutting regularly with a mulching mower. And you'll need to keep the grass from turning the beds into lawn. For that, install strips of plastic edging that extend deeply enough that grass won't migrate. This edging can have the additional benefit of helping to shore up the sides of raised beds.

A Rock-Solid Fix for Weedy Fences

The most stubborn weeds of all must be those that grow along a garden fence, where they are all but immune to mowing, shoveling, and hoeing. Weeds are particularly infuriating if they weave their way up through a fence clad with chicken wire. An attractive, permanent cure is to lay a row of rectangular flagstones under the fence, using smaller pieces as necessary to bring this stone layer flush up against fence posts. You even can use a circular saw with a masonry blade to cut notches in stones for a good fit around the posts. If the fence abuts the lawn, the flagstone row will serve as a mow strip, making a crisp edge between garden and yard.



Holding a Torch for Weeds

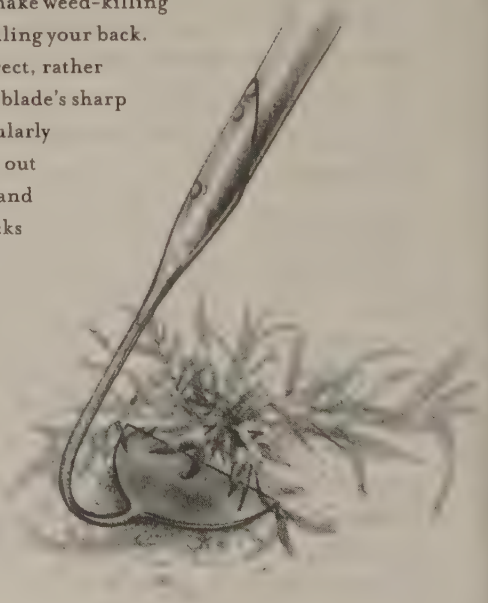
A surefire way to kill weeds is with a flamer, a type of propane torch with an extended wand. The goal isn't to burn the unwanted plants, but to heat them to the point that their cell walls are destroyed, leading to a gradual death. Flamers of various sizes are sold by mail-order garden supply firms. The smallest are handheld, of the sort used for removing paint. To take out weeds on a large scale, you can buy a backpack flamer with a 3-gallon propane cylinder. At a weight of more than 30 pounds and a price over $200, this amounts to all-out weed warfare.

Flaming is particularly useful in killing stubborn weeds along brick paths and in clearing newly turned beds in which weed seedlings are just beginning to show their heads. To deflect heat from garden plants, hold the blade of a shovel alongside the flame. Keep the garden hose handy if there is combustible brush nearby.

Not all weeds are equally susceptible to flaming. Purslane resists it. So do grasses, because much of their activity is belowground and out of reach of the flames. Perennials that grow up from a fleshy root system may require repeated treatments.

A Savage Little Hoe

The hoe is such a simple tool that you might not be all that curious about various models. But a swan's-neck hoe really is something improved in the gardener's arsenal. That graceful crook in its neck positions the blade so that you can make weed-killing slices without killing your back. You can stand erect, rather than stoop. The blade's sharp edges are particularly suited to poking out stubborn weeds and getting into cracks between bricks and flagstones.



Use Big-Shouldered Vegetables to Keep Weeds in the Dark

You've probably noticed that there isn't a lot of weed activity beneath the jumbo leaves of squash, for example. Whenever possible, try to use vegetable foliage to block out weeds, both by choosing big-leaved crops and by planting on a tighter spacing. Fast-growing vegetables also can help by getting a jump on weeds. And you yourself can help the vegetables compete, by seeing to it that you've given them adequate water and nutrients. Here's a list of weed suppressors.

Beans	Squash, pumpkins, and melons
Cucumbers	Sweet corn
Kale	Sweet potatoes
Lettuce	Swiss chard
Potatoes	Tomatoes

The Importance of Being Shallow

A weed seed buried beneath a foot or so of dirt isn't able to cause you much grief. And the soil in your garden is likely teeming with these potential specks of trouble. That—and not laziness—is the reason stated by some gardeners for preferring to cultivate shallowly. You might experiment with letting sleeping weed seeds lie by doing the same. Over the next few growing seasons, the seeds in the top few inches of soil will sprout. Assuming you take care of them before they can set and broadcast seed of their own, you're then home free—or at least weed free, relatively speaking.

Worthwhile Weeds

If your local government allows it, you might allow a patch of weeds to flourish somewhere in your yard. One nice thing about a weed patch is that it's zero maintenance—the weeds are growing there because they're happy, so there's no need for you to get involved. Second, these plants likely will provide meals and lodging to a number of beneficial insect species. Helpful predators and parasites are apt to be found in wild carrot, wild daisies, dandelions, stinging nettle, goldenrod, common sorrel, and tansy, among others. In a Michigan State University study, five or more beneficial insect species were found on shrubby cinquefoil, wild coriander, meadowsweet, evening primrose, yellow coneflower, buttonbush, hoary vervain, culver's root, and swamp milkweed.

You may find that neighbors feel threatened by the sight of wild things growing so close to their perfect putting-green lawns. If so, try calling the patch a wildflower meadow or a butterfly garden. It's all a matter of perspective.

Give Your Weeds a Vacation, Too

Gardeners return home from summer vacations greeted by a lot of mail, lawn grass long enough to bale, and weeds, weeds, weeds. To ensure that weeds take some time off, too, leave time while packing for your getaway to spread mulch in the yard's trouble spots. If your supply of bark mulch and straw is running low, lay down disassembled cardboard boxes as a stopgap and weigh them down with rocks or bricks. Mulching will not only keep the weeds at bay, but also help allow plants to get by with less watering.

A (Nearly) Weed-Free Lawn

The first step in establishing a good-looking lawn is to make sure it is a *healthy* lawn, with a dense and vigorous stand of turfgrass. Weeds will be less likely to move in if the ground is already occupied. There are a number of things you can do to keep the grass growing thick and green.

- Remove no more than one-third of the blade length when you mow, to avoid slowing plant growth.
- Keep weeds from spreading by mowing before they can set seed.
- Water deeply, rather than sprinkling often and only superficially.
- Allow mulched clippings to stay in place and fertilize the lawn.
- If necessary, periodically remove thatch either with a rake or a rented dethatcher.
- Make sure you are growing an appropriate mix of turf grass species for your region, as well as for the light conditions of your own yard. For information, check with your county agricultural extension agent or your state's agriculture department Web site.

Flaming a Stale Bed

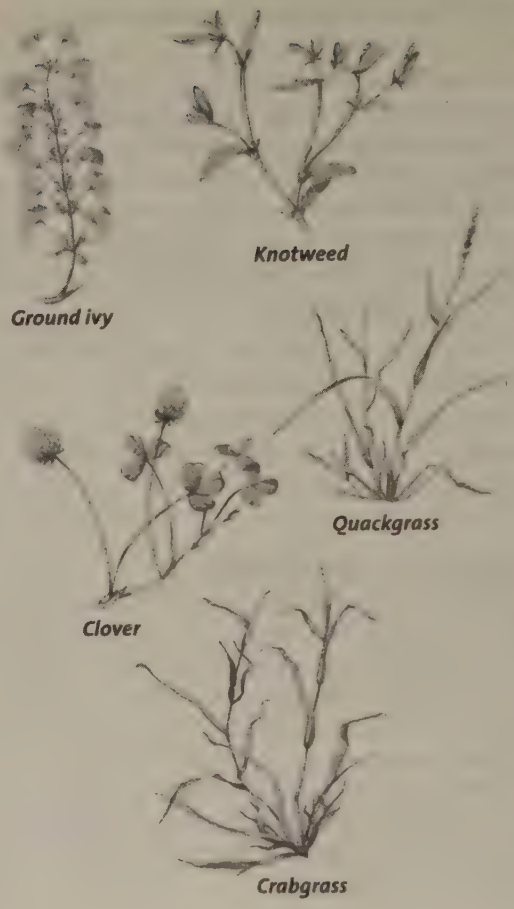
Creating a "stale bed" sounds like a bad idea, but it's a technique used by large-scale growers to make their soil relatively free of weeds. You begin by tilling the soil as you would normally but then allow the beds to sit idle during the predictable flush of new weeds. Some growers will even water the beds to encourage weeds to appear now, rather than later in the season when they will be intermingled with crops. The weeds are flamed before they go beyond the seedling stage, and the way is then clear for sowing seed or putting out transplants. You even can flame weeds that appear after sowing seed, as long as your seedlings haven't pushed aboveground.

Continued →

Reading Your Weeds

You don't necessarily need a soil test or rain gauge to diagnose the problems underlying a lousy lawn. The weeds may tell the story.

- Quackgrass does well on thin, poorly watered lawns.
- Ground ivy is apt to trouble lawns that get too little sunlight and have poor drainage.
- Knotweed shows up in lawns with compacted soil.
- Crabgrass suggests you've been mowing too short or watering too often.
- Clover is a sign that the lawn has insufficient fertility.
- If you spot chicory's sky blue blossoms, that's a sign that the soil is high in clay and also relatively fertile.
- Buttercups signal wet hardpan soils.
- Acid clay soils are apt to host a good crop of dandelions.
- Horsenettle flourishes in sandy soils high in nitrogen.
- Fumitory favors soil high in potassium.
- Eastern bracken tells you the soil likely is low in potassium and high in phosphorus.
- Wild mustard moves in to acidic hardpan soils.
- All (or a few) of the above? Then your lawn likely has a number of shortcomings that are preventing the grass from looking its best.



The Weed-Zapping Two-Step

Most of the troublesome weeds in the garden have sprouted from seeds in the top 2 to 3 inches of soil. If you cultivate the beds, then take a break for at least a couple of weeks to allow these weeds to come to life, you can nip them in the bud with a second tilling. That will mean a relatively clean slate for your seedlings or transplants. The technique works best if the soil is warm enough for the weed seeds to sprout readily, so try it when preparing the garden for fall crops. And make that delayed tilling relatively shallow, to avoid stirring up more trouble.

LET SLEEPING SEEDS LIE

It seems that really working the soil to a good depth would have to be a good thing. But it ain't necessarily so. Some aggressive weeds just love having their belowground parts chopped up. Take quackgrass, for an infamous example. This weed is trouble, as suggested by its other names: devil's grass, witch grass, and dog grass. The underground rhizomes are mighty enough to grow right through asphalt, and just a single plant can send out 300 feet of them in a year. You only make matters worse by going over quackgrass with a rototiller, because this creates thousands of pieces that each can grow into a new plant. So disturb only the very top layer of soil. Take a sharp hoe to shoots that appear, and eventually the rhizomes will be starved.

Be Wary of These Wild Ones

Some weeds and wild plants can be worse than an annoyance if they are poisonous or are armed with itch-producing chemicals.

Even if you are sympathetic to weeds, there are several common species that shouldn't be welcomed to the yard because of their potential hazards to health. That's especially true if you have inquisitive children who like to roam the grounds. Here are several of the most notorious weeds you're apt to encounter.

Poison ivy (*Toxicodendron radicans*). No surprise here. This vine supposedly was once imported to England as an ornamental—it does have glossy foliage and red berries, after all—but that sounds like horticultural folklore. If you can't eradicate the plant, teach your kids how to identify the leaves. Be cautious about embracing a pet that has been cruising an area rich in PI.

Butterfly Weeds

Weeds attract not only helpful insects, but also beautiful ones. The caterpillars that will turn into butterflies like to feed on clovers, milkweed, nettle, Queen Anne's lace, common sorrel, and butterfly weed (*Asclepias*). So allow a weed-prone edge of the lawn to go wild, and see what develops.

Deadly nightshade (*Solanum dulcamara*). This perennial woody vine attracts attention with small star-shaped purple flowers and berries that turn lipstick red when ripe. Its toxin is at its most concentrated in the unripe berries, and small children are particularly vulnerable because of their lower body weight.

Poison hemlock (*Conium maculatum*). Attractive enough to be mistaken for a garden plant, poison hemlock resembles anise or wild parsley. The entire plant is poisonous to humans: the leaves, the stems (children may become ill if they use them as straws), the roots, and especially the seeds.

Pokeweed (*Phytolacca americana*). This weed is a standout, sending up thick stems to a height of 5 feet or more. The inky berries ripen to a rich purple, and if digested they can bring on headache, abdominal pain, and severe diarrhea.

American bittersweet (*Celastrus scandens*). This woody vine finds its way into wreaths and dried flower arrangements, where it shows off its yellow-orange berries. The berries can cause stomach upset and diarrhea if ingested.

Holly (*Ilex* spp.). It's rarely thought of as an unwanted plant, but holly is worth mentioning for its attractive, yet poisonous berries. Eating them can lead to nausea, vomiting, and diarrhea.

Weeds Glossary

Acheme A dry, one-seeded fruit that does not open readily. The seed is distinct from the fruit. Common among members of the composite family.

Acute Sharply pointed.

Alternate An arrangement of leaves, branches, or flowers in which each is placed singly at different heights along the stem.

Annuals Plants that live from seed to maturity, reproduction, and death in only one growing season.

Anther The part of the stamen that bears pollen.

Apex The uppermost point; tip.

Awn A bristlelike appendage. Found most commonly on grass flowers.

Axil Upper angle where a leaf or branch joins the stem.

Axillary Situated in an axil.

Barb A rigid bristle or point, usually reflexed.

Beak A long, prominent point.

Berry A fleshy fruit containing two or more seeds, such as a tomato and a grape.

Biennial Living two growing seasons, usually flowering during the second.

Bipinnate Twice-pinnately compound.

Blade The flat, expanded part of the leaf.

Bract A small, rudimentary or underdeveloped leaf. Often found in flower clusters.

Bristle A stiff, hairlike growth.

Bulb An underground bud with fleshy scales or bracts.

Bulblet A small bulb borne on the inflorescence or stem.

Calyx All the sepals of a flower cluster considered collectively; the outer perianth whorl.

Capsule The dry, dehiscent fruit of two or more carpels.

Carpel One of the ovarian portions of a compound pistil.

Chlorophyll The green pigment necessary for photosynthesis, developed in the chloroplasts of plant cells.

Clasping Applied to leaves that partly or completely surround a stem, as seen in grasses.

Compound leaf Leaf in which the blade is divided into two or more sections, or leaflets.

Cordate Heart-shaped, with the point away from the base.

Corolla The inner set of floral leaves, or petals. Sometimes fused, as in morning glories.

Corymb A raceme with the lower flowerstalks longer than those at the tip, so that the head gives a flattened appearance. Outer flowers open first.

Culm The stem of a grass. Usually hollow except at the nodes.

Decumbent Lying flat, with the tip pointing upward.

Decurrent Extending along the sides of another, as in leaves where the blades extend as wings along the petiole or stem.

Dehiscent Opening by valves or slits, as in a seed capsule. Poppy capsules are dehiscent.

Dentate Toothed, with outward-pointing teeth.

Dioecious A plant bearing only one sex on a plant; male and female flowers are on separate plants.

Continued ➔

Disk flower The tubular flowers in the center of the head of many composites. The yellow center of the daisy is composed of disk flowers.

Divided Separated to the base.

Drupe A single-seeded fruit with a fleshy outer part. Stone fruits such as peaches and cherries are drupes.

Elliptic Oval in shape.

Entire Describes a smooth leaf margin. Not toothed, lobed, or serrated.

Fibrous Fine adventitious roots, usually in a mass.

Floret An individual flower of a cluster, head, or spike.

Fruit The ripened ovary or ovaries with attached parts.

Grain Fruit of grasses particularly; seed coat and ovary walls fused into one body.

Habit The general growth pattern of a plant or its mode of growth, such as shrubby, trailing, or erect.

Habitat The environmental conditions of a specific place in which a plant grows.

Head A short, compact flower cluster of sessile or nearly sessile florets.

Herbaceous Not woody.

Imperfect Describing flower lacking either stamens or carpels. It is "imperfect" because it has only one sex.

Indehiscent Applied to a seedpod or capsule that does not readily open at maturity.

Internode The part of a stem between two nodes.

Involucre A whorl of small leaves or bracts just under a flower or flower cluster. Generally protects reproductive structures.

Lanceolate Lance-shaped, several times longer than wide, and tapering to a pointed apex.

Leaflet One part of a compound leaf.

Poisonous to Pets

Dogs and cats occasionally munch on weeds, for whatever reason. And if they chew on certain toxic species, they can become very ill—without the ability to tell you what they've tangled with. Generally, if a plant is classified as poisonous for humans, it will have the same effect on pets. And some plants that don't trouble us are noxious to them. Dogs are adversely affected by onion, garlic, heavenly bamboo, schefflera, and dracaena. Cats can't handle calla lily, philodendron, pothos, and scindapsus.

Legume A member of the family Leguminosae. Characterized by a fruit that splits readily along two sides at maturity, such as a pea pod.

Lobed Divided to about mid-point.

Mericarp One of the two carpels of a fruit of the parsley family.

Midrib The central rib or vein of a leaf or other organ.

Monoecious Having both male and female flowers on the same plant, such as many kinds of squashes.

Netted Applied to veins, meaning they form a network pattern.

Node The part of a stem where leaves or branches emerge.

Nut A hard, indehiscent, one-seeded fruit.

Obovate Ovate, but with the narrower end at the bottom.

Opposite Two leaves or buds at a node.

Ovary The part of the pistil bearing the ovules.

Ovate Egg-shaped, with the broader end at the bottom.

Ovule An undeveloped or immature seed.

Palmate Radiating from a central point like a fan or the fingers on a hand.

Palmately compound Leaflets radiating from a central point.

Panicle An inflorescence. A branched raceme with each branch bearing a cluster of flowers. Overall, a panicle is shaped like a pyramid.

Pappus A ring of fine hairs developed from the calyx. A pappus often acts as a dispersal mechanism, as in dandelion seeds.

Peduncle Stem of a solitary flower or flower cluster.

Perennial Growing three or more seasons.

Perfect Applied to flowers having both stamens and carpels.

Perianth The floral envelope, the calyx and corolla together. Most often used to describe flowers without clear divisions between calyx and corolla, such as lilies.

Petal One of the leaves of the corolla, usually colorful.

Petiole The stalk of a leaf.

Phloem The vessels in the plant that carry dissolved sugars from leaves to the rest of the plant. One of the two vessels in the vascular bundle.

Pinnate Similar in appearance to a feather, having leaflets along each side of a common axis.

Pinnately compound Leaflets arranged on each side of a common axis.

Pinnatifid Leaflets cleft to the middle or beyond.

Pistil The seed-bearing organ with a style (a tube bearing the stigma at its apex), stigma (the part of the pistil that receives the pollen grains), and ovule.

Pistillate Having pistils and no stamens. Female.

Pod Usually describes a dry, dehiscent fruit.

Pollen The spores or grains borne by the anther, which contains the male element.

Prickle A stiff, pointed outgrowth from the epidermis or bark.

Procumbent Trailing on the ground without rooting.

Prostrate Lying flat on the ground. Some prostrate stems can root.

Pubescent Covered with short, soft hairs.

Raceme An inflorescence composed of pedicled florets growing from a common axis. Flowers open from the base upward.

Ray flower A flower growing on the margin of the disk flowers, strap-shaped. The white petals of the daisy are ray flowers.

Rhizome Underground or barely superficial reproductive stem.

Rhombic Shaped like an equilateral parallelogram, usually having oblique angles.

Rib A primary vein in a leaf or flower.

Rootstock Roots that can develop adventitious buds. Often used to mean underground reproductive stems as well.

Rosette A cluster of leaves, usually basal and shaped like a rose, or radiating from a center.

Runner A slender, trailing stem that takes root at the nodes.

Sepal One of the divisions of a calyx.

Serrate Having sharp teeth that point forward.

Sessile Without a petiole or stalk.

Sheath A long structure surrounding an organ or part.

Simple leaves Leaves in which the blade is in one piece, not divided.

Spike A flower spike with sessile or nearly sessile flowers.

Stamen The pollen-bearing, or male organ, of a flower.

Staminate Having stamens and no pistils. Male.

Stipule A basal appendage of a petiole.

Stolon A stem that bends to the ground and takes root at the tip or nodes.

Succulent Fleshy tissues storing much water.

Taproot A central, tapering, main root with smaller lateral roots. A carrot is a taproot.

Tendril A slender organ, leaf, or stem with which a plant clings to a support.

Terminal At the end of a stem or branch.

Thorn A stiff, sharply pointed, and somewhat degenerate branch.

Toothed Dentate. Having pointed edges along the margins.

Trifoliate A compound leaf with three leaflets, such as poison ivy.

Tuber A modified underground stem that usually stores food. Reproductive. A potato is a tuber.

Umbel A flower cluster that is shaped like an umbrella, such as dill flower heads.

Utricle A small, one-seeded fruit.

Valve The separate parts of a pod or capsule.

Vascular bundle The term applied to describe phloem and xylem vessels, or veins, in plants. Nutrients and water travel through these vessels to each part of the plant.

Veins The vascular bundles of leaves, containing phloem and xylem vessels.

Whorled An arrangement of three or more structures at a node..

Xylem Vessels in which water is carried from roots to the rest of the plant. One of the two vessels in vascular bundles.

ANIMAL PESTS

Overview of Animal Pests

Jeff and Liz Ball

The depredations of animal pests like moles, gophers, and deer can be so discouraging that they might make you consider giving up on your property altogether. Unfortunately, there are no quick, surefire solutions to any serious animal-pest invasion. You have three basic choices in almost all cases: You can trap the pest to kill or remove it; you can set up a barrier of some kind that will effectively deny the pest access to your yard or garden; or you can put repellents on or around your plants to keep pests away from them. This section will focus first on the most effective control measures available for your use, and then it will address various preventive measures. The section ends with a pest-by-pest description of the most effective management methods.

Controlling Animals

Effective animal pest control depends on three prime factors: timing, persistence, and diversity.

Continued ➔

TIMING

In managing animal pests, good timing is crucial. Install barriers before you expect an animal to make its appearance, and start control measures at the very first indication of damage. Unlike most insects, animals can wipe out an entire planting or even the whole garden in a very short time if the problem is left unattended.

PERSISTENCE

Some animals, such as squirrels and deer, are ingenious in foiling your attempts to thwart them. A single try at establishing a barrier may not do the job. You will have to keep trying until you come up with a control or combination of controls that finally outsmarts the wily marauders.

DIVERSITY

No single control method or preventive step is always satisfactory, even if it worked last year. Typically, a variety of strategies and devices are required, often used in combination. Placement of traps and barriers must be shifted frequently to ensure success against persistent pests.

In many cases, the only realistic option you have in controlling a pest after it has discovered your yard is trapping. Biological controls have limited effectiveness, and poisons pose hazards to the environment, pets, and children. In this section, we present control steps ranging from those with the least impact to those with greater impact on the environment.

TRAPS

Most people are unhappy about having to kill any living creature, so they prefer to use what are called "live traps," which catch the animal without harming it. Once caught, the culprit is brought out to the countryside and released.

Live-trapping animal pests isn't the best control, simply because the animal might not survive in its new environment. Any given area already has an established population of wildlife, and adding a new member puts a little more demand on the available food, water, and habitats. Using barriers to prevent pests from getting to your plants in the first place is perhaps the best solution, but if it doesn't work effectively in your backyard, you may have to resort to trapping if you want to protect your landscape.

Box traps are the safest design for live-trapping garden pests. The leg-hold design and the snare design are nonspecific, and will trap and kill pets as well as pests. Also, these traps can maim an animal instead of killing it. Box traps are available for many of the most troublesome animal pests, including chipmunks, gophers, groundhogs, mice, moles, rabbits, and squirrels. (See the box, "The Best Traps for the Worst Pests," for recommended sizes.)

Of course, you can also set traps and snares that will kill animal pests, such as the mousetrap. When dealing with the prolific rodents such as gophers, mice, and moles, this is often the best method of control.

Using Traps

Set the trap in some sheltered area near or around where you have spotted a pest in action. Do not set the trap out in the open. Conceal it with leaves, sticks, and/or grass clippings so that it looks a bit more natural. To avoid raising the suspicion of the animals you want to catch, try not to leave your own scent on the trap any more than you have to. You can boil traps with pine cones, dried leaves, or other natural materials to mask your scent. Handle the traps and the bait with gloves—preferably rubber gloves just out of the package. Follow the directions that come with the trap to set it up correctly with bait in place. After that, check the trap every day to renew the bait and see if you have trapped the culprit. Once you have trapped the animal, consult your local County Extension agent for advice on where to take it.

BIOLOGICAL CONTROLS

Compared with the wide range of predators and parasites available for insects, there aren't many biological controls available for animal pests. While badgers eat gophers and mountain lions eat deer, people do not generally have these natural predators in their backyard. However, a couple of biological controls may already be waiting in your yard.

Many homeowners have found that animal pests tend to be less troublesome when there are dogs or cats outside much of the time. Most rabbits, for example, do not feel very comfortable eating while a dog or cat is on the prowl. Male dogs and cats will mark their territories with scent, and these boundary marks can sometimes keep rabbits from venturing onto your lawn. If you let your pets play or stay in the yard, make sure their rabies shots are up to date.

Poisons

There are no poisons that are not in one way or another potentially dangerous to pets and children. Do not use poisons to control animal pests in the landscape.

Preventing Pest Problems

Over the years, desperate homeowners and gardeners have resorted to a number of ingenious tactics in the battle against animal pests. Here are some of the most successful preventive measures, from fences to bars of soap.

BARRIERS

If you know from past experience that one or more animal pests are likely to attack your backyard, then the best approach to controlling them is to deny them access in the first place. There are a number of techniques for preventing access, some more effective than others. If you want to use a barrier, that usually means building some kind of fence.

FENCES

Here you have a choice: You can put up a temporary fence that is designed to be movable and easily erected, or you can take the time and go to the expense of building a permanent fence to solve the pest problem once and for all. There are any number of fence designs in both categories designed to keep animals out of a garden bed or stand of shrubs, and there are just as many stories about how some of those animals, especially raccoons and deer, overcame the barrier and still entered the garden sanctuary.

Fencing off a small, garden-sized section of your property is relatively easy, or you can fence around the entire yard. Remember that various animals can jump, dig, and squeeze through small places. The size of the fence depends on which pest or pests you are trying to thwart: Make sure your fence is high enough to be effective. To keep deer out, it must be at least 7 to 8 feet high. A 3-foot fence will keep out gophers, groundhogs, and rabbits. Even if burrowing pests are not currently a problem, if you are going to the trouble of erecting a permanent fence, it is a good idea to bury at least 6 inches of it in the ground to forestall any future subterranean invasions. Finally, be sure your fence is a solid barrier—spacings between boards or other materials should be less than 2 inches. The actual design of your fence and the materials you use will ultimately depend on how much time and money you wish to spend.

REPELLENTS

For many years, gardeners have been trying to find substances that will repel animals from their yards and gardens. There are now on the market a number of products that promise to successfully ward off various animal pests, including birds, rabbits, raccoons, and deer. In addition, there are dozens of home remedies invented by frustrated gardeners under siege from some troublesome animal. These products work better for some gardeners than others, and no one product seems to be foolproof all of the time in all areas of the country. If you prefer not to rig a barrier, then you may wish to experiment with one or more of these repellent products; however, you must not be too confident about their effectiveness in your particular landscape.

Repellents come in two general forms—those that repel by odor and those that repel by some visual, tactile, or audible characteristic.

Using Scent to Repel Pests

Various animal repellents are sold commercially in many garden centers and through mail-order catalogs. Big-Game Deer Repellent, Hinder, and Ro-Pel are a few examples. The success of the scent repellents is quite spotty. Some homeowners swear by them; others find they don't work at all. Dozens of home remedies have been reported in garden magazines, and several scent repellents seem to be particularly popular.

The Best Traps for the Worst Pests

Chipmunks

5" x 5" x 15" box trap. Bait with peanuts or other nut meats.

Gophers

Standard wooden-based rat traps, a two-pronged pincher trap (called the Macabee trap), or a squeeze-type box trap. Bait with a large amount of grain, sunflower seeds, peanuts, or other nut meats.

Groundhogs

12" x 12" x 36" box trap. Bait with nut meats or pieces of fruit.

Mice

5" x 5" x 15" box trap, standard wooden-based mouse traps, or glue boards especially designed for mice. Bait with nut meats, dried fruit, or bacon.

Moles

Choker or harpoon-type trap. No bait needed.

Rabbits

10" x 12" x 30" box trap. Bait with fresh greens, carrots, or fresh clover.

Squirrels

8" x 8" x 24" box trap. Bait with peanuts, sunflower seeds, walnuts, almonds, oats, or melon rind.

Cat Litter. Many gardeners find that used cat litter repels rabbits when it's sprinkled on the lawn and around ornamentals, and repels moles and gophers when it's buried. The advice is to sprinkle well-used litter around vulnerable plants, replacing it each week and after each rain. For moles and gophers, dump the litter right into the holes of the active burrows. But use caution when handling and distributing litter: Cat feces may contain toxoplasmosis parasites, which can infect humans. Do not use litter around edible plants.

Hair. Lots of homeowners report that they have kept deer away by hanging human hair from the trees around their landscape. Use mesh bags with a ⅛ inch or smaller mesh. Place at least two large handfuls of hair in each bag and hang them from the branches of trees and shrubs at a height of about 30 inches. They should be no further than 3 feet apart. This method works best if you replace the hair every four days, which means that you

Continued →

really need to be friends with a barber or hairdresser to make this system work.

Soap. Deer are also repelled by strongly scented soap. Use bars of deodorant soap, keeping them in their wrappers so they'll last longer. String them on wires and hang them about 4 feet above the ground (deer-nose height) on the branches of the trees or shrubs to be protected. Space them no farther than 3 feet apart. Ornamenting your trees and shrubs with soap in late winter provides protection throughout this season, when hungry deer cause widespread damage to tender new shoots.

While gardeners have tried many other materials, such as ammonia, vinegar, blood meal, and manure from zoo carnivores to repel animals through noxious odors, none have been proven uniformly effective. That is why we hesitate to recommend them as repellents for animal pests.

Using Tactile and Audio Tricks

A host of audio, visual, and tactile tricks that keep pests away have been tried and recommended. The following two techniques are frequently recommended. Though no scientific research supports their effectiveness, their popularity suggests that they might be worth a try.

Pepper Technique. Pepper is organic, so it doesn't harm the soil, and it's very inexpensive. Sprinkle black or hot pepper all over and around plants. It reportedly repels rabbits and squirrels. Reapply the pepper after rain.

High-Tech Vibrations. The Rodent-Repelling Garden Stake is a commercial device from Germany. It is battery-powered and vibrates at 60-second intervals to repel burrowing rodents and moles over as much as ⅓ acre. Technology like this has its price, and this gadget carries a hefty price tag (over $75). It is carried by Hammacher Schlemmer.

These schemes just scratch the surface of the long list of home remedies for animal pests. In the rest of this chapter we will look at individual animal pests and the best prevention and control measures for each. Keep in mind that if you have neither the time nor the inclination to experiment, or lack the patience to try multiple approaches, then the most reliable control device is a trap, and the best prevention is an effective barrier.

Guide to Animal Pests

Jeff and Liz Ball

People create lovely landscapes for their pleasure and enjoyment. However, a property with a lovely lawn and a variety of healthy trees, shrubs, vines, and ground covers will also, inevitably, attract pest animals. While many of these animals are appealing in nature, they are seldom welcome in the yard. As they go about raising a family, eating, and sleeping, they inadvertently damage plantings. What follows in this section are profiles of the most troublesome pests and options for controlling and preventing problems. Some of these solutions have been proven more effective than others; you'll need to try them to see how they work in your landscape.

Chipmunk

Chipmunks are territorial animals. Males and females live apart rather than in communal burrows. They have a keen sense of smell and a strong sense of curiosity. In the course of gardening, your scent is transferred to plants, bulbs, or seeds that may be planted in the chipmunk's territory. The chipmunk feels its territory has been invaded; curiosity overcomes caution, and the animal digs up the plant.

SIGNS OF CHIPMUNK DAMAGE

Plants and bulbs are dug up, especially just after they have been planted in the soil.

BEST CONTROL STRATEGY

Traps are about the only effective control for chipmunks. Use a 5" x 5" x 15" box trap, baited with peanuts or other nut meats.

STEPS TO PREVENT CHIPMUNK DAMAGE

Repellents

Ro-Pel repels chipmunks by odor and taste. Spray it on bulbs, seeds, and landscape plants before planting them. Be sure to wear gloves and a mask; the label warns that you should avoid skin contact and inhalation of the fumes. Ro-Pel is available from Burlington Scientific Corporation and Ringer Corporation.

Barriers

Once any type of plant that has previously been bothered by chipmunks is in the ground, cover it with a piece of screening or fencing. Ordinary window screening or fence with a mesh of up to 1 by 2 inches will suffice. Place the screening on top of the plant, securing it with stones. The plant may be slightly flattened, but will recover in a few days. On bigger plants, place the screen flat on the ground around the base (fencing that is heavier need not be secured). The screening discourages the chipmunks from coming near the plant. Leave it in place for about a week, until your scent dissipates and the plant has established itself. Screening works over bulb beds as well.

Antitranspirants

Recent research suggests that spraying bulbs with an antitranspirant spray (usually applied to the foliage of broad-leaved evergreens to keep them from dehydrating and wilting in winter) masks the human scent, so the chipmunk will overlook

them. Commonly available antitranspirants include Wilt-pruf, Pro-Tec, and VaporGard. These products are widely available in garden centers and nurseries.

Deer

Deer can spell disaster for a landscape. They usually feed in the late evening or early morning, when no one is around. One or two deer can virtually destroy an ornamental or vegetable garden in one night. Far from finicky eaters, they devour almost everything found in the flower and food garden, as well as foliage and bark from trees and shrubs. Various species of deer thrive throughout the United States and Canada.

SIGNS OF DEER DAMAGE

Deer can chew young plants to the ground. On fruit trees and other ornamental trees and shrubs, deer will eat leaves, flower buds, shoots, fruit, and even bark.

VULNERABLE PLANTS

Deer will eat almost anything: fruits, vegetables, flowers, and foliage. On small trees, especially fruit trees, they relish the growing tips in summer and the buds in winter.

BEST CONTROL STRATEGY

The most effective way to control deer is with a wall or fence.

STEPS TO PREVENT DEER DAMAGE

Barriers

A 6-foot solid wood or masonry wall will deter deer even though they could jump over it, because they are less likely to bother a yard or garden they can't see. For small areas, homeowners have had success with a double woven wire fence 8 to 10 feet tall.

Don't skimp on fence height—a wire fence *must* be that tall to be effective. If you don't care about looks or are desperate enough to try anything, a double fence of string has also been proven effective. The second fence should be 3 feet inside the first; both should have three strings and be 3 feet tall. The double fence confuses the deer and they won't try to jump. Make sure the string is easy to see.

Repellents

Many times a particular odor repels deer. However, it must be kept fresh to be effective. One handy trick is to mix your repellent agent with an antitranspirant such as Wilt-pruf, Pro-Tec, or VaporGard to give it season-long effectiveness.

Soap

For the orchard or any newly planted trees, string bars of deodorant soap on wire and hang them on outer tree branches about 30 inches from the ground and no farther than 3 feet apart. Leave soap wrappers on so the soap will last longer.

Eggs

Another effective control is an egg spray. Louisiana researchers found that a spray of 18 eggs in 5 gallons of water protected an acre of soybeans from deer. The deer were repelled by the smell of decomposing eggs, which in that dilution was too faint for humans to detect.

Hair

Human hair, available from beauty parlors and barber shops, provides some protection if the deer aren't desperate for food. Use mesh bags with 1/8-inch or smaller mesh, and fill each with at least two large handfuls of hair. Hang them from outer tree branches about 30 inches from the ground and no more than 3 feet apart.

Hot Sauce Spray

Another effective remedy is a homemade hot sauce or spray of Tabasco sauce. Mix 1 to 2 tablespoons Tabasco sauce and 2 tablespoons antitranspirant in 1 gallon water. Spray vulnerable shrubs and plants with this mixture. Be sure to respray after it rains.

Garlic

Recent research has shown that selenium, which gives off a garlicky odor, prevents deer from eating tree shoots and seedlings. Since the selenium in garlic is the component responsible for the notorious "garlic breath," spraying a garlic solution on trees might have a similar repellent effect. Like hot sauce, it would have to be reapplied after rains. And remember, you might be repelled by your garlicky trees too! An alternative is planting a time-release garlic capsule (available at health-food stores) at the base of each tree or shrub.

Commercial Repellents

If home remedies don't work, there are many commercial products that may be worth a try.

Big Game Repellent (Deer Away). This product repels by odor and is made from eggs, which repel deer as they decompose. It's a highly effective repellent. Apply it according to package directions and reapply after rains.

Bonide Rabbit-Deer Repellent and Bulb Saver. One taste of this stuff and rabbits and deer should walk away. Spray, brush, or dip branches. Use it for shrubs, evergreens, trees, and fruit trees. Bonide Repellent will last three to six months. It is available from Bonide Chemical Company.

Chew-Not. This product also repels by taste. Spray, brush, or dip branches in the solution. It is primarily used on fruit trees and some varieties of evergreen. Chew-Not's disadvantage is that it leaves an unattractive white residue on the plants due to its eggwhite consistency. It is available from Nott Manufacturing Company.

Continued ➔

Hinder. This is a soap-based formulation that repels by odor. It must be reapplied after heavy rains. It comes as a spray, and is available from Uniroyal-Leffingwell Chemical Company.

Ro-Pel. Both the odor and taste of this product repel pests. Spray it on both sides of the leaves of landscape plants. Be sure to wear gloves and a mask when using it. Ro-Pel is available from Burlington Scientific Corporation and Ringer Corporation.

Gopher

Gophers range in length from 6 to 12 inches. They have a thick body with small eyes and ears. Their sense of smell is excellent. They seldom are found aboveground. Once gophers arrive in your yard, they resemble a small invasion force. One acre can feed and house 16 to 20 gophers, so it is easy to see why they can be a very serious problem. Gophers range from Indiana west to the Pacific Ocean. The most common is the pocket gopher (*Geomys bursarius*).

SIGNS OF GOPHER DAMAGE

Gophers push soil out of their holes, creating distinctive fan- or crescent-shaped mounds on the surface of the ground. After digging a mound, they may close up the entrance hole with a soil plug. One gopher can create several mounds a day. Gopher tunnels, about 2 inches in diameter, follow no pattern, running from a few inches to 2 feet below the soil. You know you have gophers when your plants are damaged in areas where there are fan-shaped mounds. Sometimes plants simply disappear—one morning you'll look out and find that a gopher has yanked your pansies down into its tunnel.

VULNERABLE PLANTS

Gophers eat the underground parts of garden crops and a wide variety of roots, bulbs, tubers, grasses, and seeds. They can damage lawns, flowers, vegetables, vines, and trees. Their mounds sometimes smother small plants, and they can girdle and kill young fruit trees.

BEST CONTROL STRATEGY

A sure way to drive this pest away is to determine the location of all the entrances to its tunnel system and then fumigate. Find a piece of hose material that can be attached to the exhaust of a power lawn mower. Stick one end of the hose into the gopher's tunnel, then seal the opening with soil. Next, drop some oil onto the inside of the hot exhaust pipe to create smoke, and attach the other end of the hose to the smoking pipe. After a few minutes, you should see smoke coming from all other entrances to the tunnel system. You may see gophers emerging as well.

Once you identify all the entrances to the tunnel system, you have several choices. You can seal them with piles of soil and continue to blow exhaust from the power mower into the tunnel, killing the inhabitants with poisonous carbon monoxide fumes, or you can put sulfur into the holes and seal all the entrances. The cheapest source of sulfur is one of the emergency highway flares that come with auto safety kits or are found in auto supply stores. Cut through an emergency flare with a sharp knife (not a saw). Dig into the runway, then pour the flare powder directly into the tunnel. Cover this hole, as well as all the exit holes that you have discovered. The more airtight the tunnel system is, the more anxious the gophers will be to leave. Once you are sure that the gophers are gone, seal the tunnels securely with soil. You'll know the gophers are gone when you no longer see fresh mounds around your property.

Another option is to place small ammonia-soaked sponges into each gopher hole and then seal them all. Gophers will abandon their burrows in a hurry. The best time to use this control is in early spring.

OTHER OPTIONS FOR CONTROLLING GOPHERS

Flooding

Set up traps over the openings of the gopher tunnels, then locate the main gopher burrow by probing the soil with a long screwdriver or similar probe. When the probe hits the main tunnel, it should suddenly drop about 2 inches. Once you've located the main tunnel, insert a garden hose into it. When you turn the water on, it will flow in both directions throughout the tunnel system. The gopher will try to escape by exiting from one of the mounds. It can then be trapped.

Traps

Trapping can effectively eliminate gophers. Place standard wooden-based rat traps in shallow pits near burrow entrances. Cover the trap trigger with a thin layer of dirt and lure your victims to the traps by sprinkling grain on the dirt.

You can also trap gophers with a Macabee or other pincher trap, or with a box trap such as the Gopher Getter. You'll need two or more traps. Set them with special care. Wear gloves to prevent human scent from contaminating the devices. If you inadvertently touch the traps, you can wash them in soapy water. Open up the main burrow enough to allow you to insert two traps, one facing in each direction. The gopher will run over the trigger mechanism, regardless of the direction in which it is moving. Attach strong twine or rope between the trap and a stake driven into the ground. This prevents the rodent from pulling the trap deep into the burrow. Use a wooden board, cardboard, or other sturdy material to cover the traps, and be sure to sift dirt around the edges of the covering to exclude light. If the gopher sees light, it will push soil toward it, tripping the trap without being caught. If you don't catch any gophers within three days, pull out the traps and reset them in a new location.

STEPS TO PREVENT GOPHER DAMAGE

Barriers

Bulb beds and individual shrubs or trees can be protected with ½-inch-mesh wire if it is laid on the bottom and sides of the

planting hole. Be sure to place the wire deep enough so that it does not restrict root growth.

Gophers occasionally feed on the bark of certain trees, particularly stone fruits such as peaches and cherries. It is wise to protect the trunks of vulnerable trees with cylinders of ½-inch galvanized hardware cloth sunk 12 inches underground and rising 12 inches above the surface.

REPELLENTS

Cat Litter

Dump several scoops of well-used cat litter right into each burrow entrance. As mentioned at the beginning of this section, do not use this trick in the food garden. It is an option for the flower garden and general landscape, if children won't be playing in the soil.

Ro-Pel

A commercial product, Ro-Pel can be used to keep gophers away. Both the odor and taste of this product repel these rodents. Spray it on both sides of the leaves of landscape plants. Be sure to wear gloves and a mask when using it. Ro-Pel is available from Burlington Scientific Corporation and Ringer Corporation.

GoPherIt

GoPherIt is a battery-powered sound-emitting device that you can insert into the lawn or garden. It emits sound waves every 15 seconds, and will keep gophers out of areas of up to 100 feet in diameter. The sound waves cannot be detected by humans or nonrodent pets. GoPherIt is available from Ryans Company and Ringer Corporation.

Mole

Moles do not eat plants, but they do eat lots of grubs, beetles, earthworms, and other soil dwellers. Moles cause trouble because they harm the root systems of young plants when they tunnel through the soil in search of food. This damage is compounded by the fact that they can spread disease from plant to plant. In addition, other pests that are more harmful, like field mice, use mole runs. Several mole species are known; they are found throughout the United States.

SIGNS OF MOLE DAMAGE

In their search for food, moles make an extensive network of tunnels, many of which are used only once. They are solitary animals, and it is likely only one or two moles are responsible for all the damage to your lawn or garden. Moles are active all year long. When cold weather comes, they follow the earthworms deep into the soil below the frost line. Mole tunnels can be distinguished from gopher tunnels by the fact that they do not have the characteristic fan-shaped mound at the entrance that gopher tunnels have.

VULNERABLE PLANTS

Lawns rich in grubs and earthworms are most likely to be riddled with molehills. Young seedlings in the early spring can be harmed by moles tunneling in search of grubs and other insects.

BEST CONTROL STRATEGY

Traps can be effective, but you have to be persistent. The best time to trap is in early spring when the first mole ridges appear. To find out which runs are used as "travel lanes," step lightly on a small section of several tunnels so that you disturb but do not completely collapse them. Mark these sections with stones or garden stakes. In two days, note which ones are raised—those are active runs and good locations for setting a trap. You can restore the turf over unused tunnels with a lawn roller or by treading on them.

Choker traps (such as the Nash mole trap), scissor-jawed traps (such as the Out O' Sight), and harpoon traps (such as the Victor mole trap) do catch moles when used properly. Install these traps according to instructions that come with them. They all basically work by springing when a mole sets off the trigger-pan as it attempts to raise a flattened portion of its run.

OTHER OPTIONS FOR CONTROLLING MOLES

Digging

As an alternative to trapping you can try digging out moles. Because moles may be active at any time of the day, it is often possible to see the soil ridging up as the mole moves along. Put a shovel into the soil right behind the mole, and flip the animal out into a bucket, which you can then fill with water to drown the culprit.

Flushing

A technique that's effective when mole runs are short is to flush the little animals out with water. Just open the main run, insert a garden hose, and turn on the water. When the water spreads through the tunnels, adult moles will try to escape through other exits, where you can kill them with a shovel. If you flood the runs in spring, you will also drown the young in their nest.

STEPS TO PREVENT MOLE DAMAGE

Get Rid of Grubs

Beetle grubs feed on plant roots and in turn are eaten by moles. Remove the grubs and your lawn will be less attractive to moles. Kill Japanese beetle grubs in your soil with applications of *Bacillus popilliae* (commercially available as Doom and Grub Attack, among other brand names). Other beetle grubs can be controlled with parasitic nematodes (sold as Bioquest).

Continued →

Repellents

Cat Litter

You might achieve success with the strong odor of well-used cat litter. Dump several scoops of litter right into the mole's burrow. A sprinkling of tobacco or red pepper into each burrow may also deter moles.

Mole Evictor

The Mole Evictor is a battery-operated vibrating device that you set in the soil. The vibrations emanating from it supposedly drive moles away for good. For information contact Ryans Company.

GoPherIt

Like the Mole Evictor, GoPherIt produces battery-powered vibrations that clear moles within a 50-foot radius. It is available from Ryans Company and Ringer Corporation.

Windmills

Another vibration trick is to set windmills (available commercially through garden supply catalogs) in mole runs. These windmills create vibrations that seem to deter moles. A less expensive alternative is to insert a child's pinwheel into the tunnel ridge. Empty glass soda bottles work along the same principle. Set a bottle straight down into the mole run, open end up. The wind blowing across the opening of the bottle creates vibrations that spread along the mole tunnel.

Rodent Rocks

Rodent Rocks are porous lava stones that have been soaked in an organic repellent containing onions and garlic. When the rocks are buried 6 inches deep and 2 to 4 feet apart, their odor is claimed to effectively repel moles for 4 to 12 months. Circle the lawn with rodent rocks for best effectiveness. You can buy a package of about 60 Rodent Rocks from Gardener's Supply Company.

Barriers

Moles will avoid hard, stony soil, which is difficult to dig through. You can create an effective barrier by digging a trench 2 feet deep and 6 inches wide around vulnerable areas. Fill the trench with heavy clay and stony and/or compacted soil and keep it dry. You can pave or mulch the barrier to create an attractive path around the lawn or garden.

NATURAL PREDATORS

Cats are natural predators. They'll kill moles, but they won't eat them because of their bad taste.

NOTES AND RESEARCH

No evidence exists to support claims that castor beans (sometimes called mole plants) keep moles away, or that daffodil bulbs or dandelions work either.

Mouse

A number of different types of mouse may nibble on your landscape plants. The field mouse (also called the meadow vole) is chunky in build, with small ears that are almost concealed in fur. They are white underneath and gray-brown on top. The house mouse, which is less likely to damage your landscape plants, is gray all over, with large, distinct ears. The white-footed mouse and related deer mouse range over most of the continent. They have whitish underparts like the field mouse, as well as whitish legs and feet and tails over 2 inches long.

SIGNS OF MOUSE DAMAGE

Mice are known to move into mole tunnels and use them to gain access to plant roots. They create surface trails through long grass, weeds, and brush, and can also burrow underground. They are most damaging in winter, when they gnaw the bark of young shade or fruit trees, sometimes girdling and killing the trees. Because of their tunneling habits, mice can chew bark from trunks several inches underground, girdle trees at ground level, or reach higher branches by digging through snow. Orchardists report that voles can kill scores of fruit trees in an orchard during a single winter. Tree-girdling usually occurs between October and April. Mice may also overwinter in the mulch placed around strawberries or perennial flowers, where they chew on the roots. They are generally active all year round.

VULNERABLE PLANTS

Roots of vegetable and flower plants in the garden are fair game for mice. These rodents also gnaw on roots of young trees and shrubs, as well as on bark buried under the snow during the winter months.

BEST CONTROL STRATEGY

The traditional mousetrap still works. The most effective way to reduce mice through trapping is to buy a large number of snap-traps and plan a one- or two-night massacre. Buying a few traps to catch mice over a long period of time does not work as well. Bait the traps with a tiny dab of peanut butter or bacon, or a 50=50 mix of peanut butter and uncooked oatmeal. A good technique is to bait the traps for two or three nights without setting them. Then when you finally do set the traps, you'll catch the mice by surprise.

A steel drum with bait inside makes a very simple homemade mousetrap. The mice scramble into the standing drum, and once they are inside, they can't climb out. You'll have caught them red-handed.

OTHER OPTIONS FOR CONTROLLING MICE

Glue Board

Besides the basic mousetrap, there is also a product on the market called a glue board. This is a sheet of extremely sticky material that literally stops mice in their tracks when they try

to run across it. Once you've caught a mouse, dispose of both the glue board and the pest. J. T. Eaton & Company carries glue board traps.

Vitamin D Bait

A vitamin D-pelleted bait causes a calcium imbalance in the mouse's blood. Mice stop feeding after eating the pellets and die in two to four days. This bait is toxic only to rodents. It is available from Necessary Trading Company and Natural Gardening Research Center.

STEPS TO PREVENT MOUSE DAMAGE

Ro-Pel

Mice do not like the taste of Ro-Pel. Spray it on both sides of the leaves of landscape plants. Be sure to wear gloves and a mask when using it. Ro-Pel is available from Burlington Scientific Corporation and Ringer Corporation.

Barriers

Plastic Guards

Commercial plastic wrap-around guards placed around the base of trees will prevent mice from chewing on bark, but these guards must be installed each fall and removed each spring. If they are left on year-round, the trunks become more vulnerable to borer attack and the bark remains tender and slow to harden off.

Hardware Cloth

Galvanized hardware cloth makes a durable mouse-proof guard that can be left on all year. Buy 14-inch mesh in a 24-inch width. Cut the hardware cloth wide enough to completely encircle the tree. If you plan to leave it on year-round, allow plenty of room for the trunk to expand as it grows. Make a cylinder around the trunk, fastening the edges securely. Bury the cylinder at least 2 inches deep to keep mice from digging under it. Make sure the top of the cylinder extends above the snow line.

Other Options

Good sanitation is one way to discourage mice from visiting your yard. Clean up all possible food sources, such as vegetables left in the garden at season's end and fallen apples, crabapples, or other fruit. Be sure to use rodent-proof containers of metal or glass to store seeds and birdseed, and keep birdseed swept up.

Always pull mulch away from the base of young shade and fruit trees in the winter. Don't mulch perennials or strawberries until the ground freezes hard. Putting mulch down early invites the mice to set up housekeeping and gives them easy access to roots in unfrozen soil.

Keep an area of at least 3 feet clear around trees, removing tall grass, weeds, and shrubby growth. Mice do not like to come out in the open and will hesitate to cross that bare space to gnaw on the trees.

Natural Predators

Any owls and snakes on your property will help keep the population of mice under control. Of course, one of the best rodent controls known is the house cat.

Rabbit

Rabbits have shown themselves to be extremely adaptable to human environments. Cottontails are active mainly from dusk until midmorning and spend the warmer part of the day in shaded areas. They may hide under thick shrubs or beneath garden sheds. The Eastern cottontail is the species usually found nibbling in the yard and garden, but various species of rabbit are found throughout the United States and Canada.

SIGNS OF RABBIT DAMAGE

Herbaceous plants, especially young ones, will be nibbled down to the base. In winter, rabbits remove a considerable amount of bark from young trees, and they chew the new shoots.

VULNERABLE PLANTS

Rabbits' favorite foods include carrots, geraniums, grasses, lettuce, marigolds, peas, strawberries, tulip shoots, raspberry canes, weeds, and the bark of young shrubs and trees, particularly euonymus, honey locust, and sumac. They especially relish young bean growth and the bark of young fruit trees (apple trees are the all-time favorite). Rabbits don't like corn, cucumbers, or squash, and will only eat evergreen bark if they're really desperate.

BEST CONTROL STRATEGY

Trapping is the most effective way to control rabbits. Commercial box traps measuring 10" x 12" x 30" are recommended. Rabbits are more likely to enter a dark trap than one that's well lighted, so put a tarpaulin over the trap.

STEPS TO PREVENT RABBIT DAMAGE

Barriers

Ordinary chicken-wire fence can rabbit-proof the flower garden, but it isn't very attractive. Bury the fence 6 inches into the soil and extend it at least 2 feet aboveground. Make sure the holes in the mesh are smaller than 2 inches—1 to 1½ inches is ideal.

Tree Guards

Commercial Wrap and Alternatives

Tree guards are an essential piece of equipment in the war against rabbits. When preparing newly planted trees or an orchard for the winter, wrap the lower portion of trunks with

Continued ➔

commercial tree wrap, burlap, aluminum foil, or a piece of metal window screen. The wrapping should be 2 feet above the height of the deepest expected snow cover—rabbits can walk on top of the snow. In winter, tramp down the snow around your trees so rabbits can't chew on low limbs. Remove protective wrappings each spring to prevent the trunks from becoming tender and to avoid attracting borers.

Wire Guards

You can put wire guards around individual plants, shrubs, or trees if you have the time and patience to make them. Make a cylinder around each plant with hardware cloth, attaching it to stakes to keep it upright. Make the guards higher than 18 inches so a rabbit can't stand up on its hind legs to reach its lunch. If you use wire around tree trunks, extend it 2 feet above the projected snow depth.

Repellents

Repellents may help you reduce rabbit damage. As mentioned in the beginning of the chapter, these vary in effectiveness. In the case of rabbit control, taste repellents are often more effective than scent repellents.

Scent Repellents

You can choose from a wide range of scent repellents to keep rabbits away from your plants. Rabbits tend to avoid anything that smells of blood. Sprinkling dried blood meal on the soil around vulnerable plants may keep rabbits away, but you'll have to reapply it after each rain.

Some gardeners have reported that vinegar wards off rabbits. Save a few corn cobs after a meal and cut the cobs in half. Soak them in vinegar for 5 minutes, then scatter them throughout the flower or vegetable garden. Two weeks later, soak them again in the same vinegar. You can keep reusing this vinegar; just keep it in its own labeled bottle.

Other rabbit repellents reported effective by some homeowners include lion and tiger manure (sold by some zoos as ZooDoo); a solution of cow manure and water applied as a spray; onions interplanted among crops; fish tankage and bonemeal; and soybeans planted adjacent to the garden. Sprinkle or place repellents immediately around the target plants.

Taste Repellents

You can purchase commercial taste repellents or make one at home. During the growing season, discourage rabbits by spraying nicotine sulfate on your garden. Prepare the spray by mixing ½ teaspoon 40 percent nicotine sulfate in 1 quart water. An even easier repellent to use is black or hot pepper. Simply sprinkle it all over and around plants.

Ro-Pel is a taste repellent. It can be dusted on plants, or you can follow the package instructions to make a spray. Ro-Pel is available from Burlington Scientific Corporation and Ringer Corporation.

A combination antitranspirant and pest repellent is Bonide Rabbit-Deer Repellent & Bulb Saver, available from Bonide Chemical Company. The branches of shrubs, evergreens, trees, roses, fruit trees, ornamentals, and nursery stock should be sprayed or brushed with or dipped into this product. The effect will last three to six months.

Visual Repellents

Inflatable or cast plastic snakes and owls look lifelike and are readily available from most mail-order garden catalogs. These pseudo-predators will frighten rabbits away from the tree or garden area they're placed in. Move them every few days so the rabbits won't catch on.

Eliminate Daytime Cover

One way to reduce the rabbit population in the yard is to remove brush piles, one of their favorite daytime resting places. Clear out overgrown walls, fences, and ditches. Lack of cover will discourage rabbits from hanging around. Anything you can do to eliminate sanctuaries will help solve the rabbit problem; however, if you live next to a wooded area, there may be too many hiding places to deal with in this manner. Fortunately, nearby big trees may help, since they will encourage predators such as owls and hawks.

Squirrel

Eight species of squirrel live in the United States. The most common are the eastern gray squirrel and the fox squirrel, which can make nuisances of themselves at bird feeders and cause occasional problems in the landscape.

SIGNS OF SQUIRREL DAMAGE

Squirrels eat crocuses and other bulbs. They often make holes in the lawn or garden as they search for nuts buried earlier in the season.

VULNERABLE PLANTS

Squirrels eat nuts (including green and ripe walnuts and almonds), fruits (such as oranges, apples, and avocados), buds, bulbs, and bark. They love birdseed.

BEST CONTROL STRATEGY

You can catch a squirrel in a medium-sized box trap baited with fruit, nuts, or peanut butter.

STEPS TO PREVENT SQUIRREL DAMAGE

Scent Repellents

Ro-Pel, a commercial product, smells and tastes awful to squirrels. Soak bulbs in Ro-Pel before planting them, and squirrels will leave them alone. This repellent is available from Burlington Scientific Corporation and Ringer Research.

Sticky Repellents

The Squirrel, also commercially available, is a sheet of paper coated with gel. The unpleasant sensation of gel on their feet discourages squirrels from encroaching on the protected area. This paper is available from J. T. Eaton & Company.

Squirrel Baffles

To keep squirrels out of bird feeders, put a baffle on the pole beneath the bird feeder or on the wire it's strung on. Baffles are available from the same companies that sell bird feeders and supplies. You can also make your own from stovepipe.

Preventing Damage from Animals

Barbara Pleasant

A hungry raccoon, deer, squirrel, or rabbit can do more damage in an hour than most insects can do in a week, so they can be formidable garden pests. Prevention or early intervention is crucial, because once hungry animals discover good food in your garden, they become much more difficult to manage. Hunger and the availability of other foods are important variables, because starving animals will often eat plants they normally leave alone.

Try Scent Fences

In landscape situations where an actual fence is not practical, you may have luck deterring animals with various scents. Odor repellents are useful when you have just a few plants in need of protection, and in situations where the pest animals have plenty of other places to go in search of food.

If you choose this "scents-ible" approach to plant protection, be prepared to keep raising a stink as long as animal pests pose a threat. Most repellents need to be refreshed as their aromas fade, especially if they're exposed to the elements. Here are some widely used repellents with reputations for success in keeping plant-munchers at bay.

- **Deodorant soap.** Popular for protecting fruit trees from deer browsing, aromatic bars of soap hung 3 to 4 feet above the ground often are effective. Place a bar in a mesh bag, or drill a hole through the middle and hang on a piece of twine. Each bar will protect an area of about 1 square yard, so large trees and shrubs may need more than one bar. This is a great use for the small bars of soap often provided by hotels.
- **Predator scents.** Rabbits and deer instinctively avoid areas that seem to be frequented by predators. Hang the blanket your dog has been sleeping on over the garden fence, or tuck tufts of dog hair (or human hair) into mesh bags and hang them around your garden or on your favorite shrubs. Put small amounts of used cat litter into the bottoms of coffee cans that have several holes punched in their sides and set them around the outside of your garden (never allow used cat litter inside your garden).
- **Hot stuff.** All mammals can taste the fire in hot peppers, so dousing plants with a spicy spray will often deter casual munchers. Combine 2 cups of water, 2 tablespoons of Tabasco sauce, 1 teaspoon of hot chili powder, and a squirt of dishwashing liquid, and spray or sprinkle it liberally over plants that are being bothered by squirrels, rabbits, deer, or other four-legged creatures. Reapply this spicy cocktail after heavy rains, which usually wash plant leaves clean.
- **Castor oil.** A powerful repellent for moles, castor oil also has proven useful in repelling squirrels, chipmunks, and gophers. If these varmints are rooting around in your flower beds or containers, a castor oil solution is an easy-to-apply deterrent. In a glass jar, combine 1 ounce of castor oil with 1 tablespoon of dishwashing liquid and 1 cup of warm water. Shake the jar to mix the solution. Pour this mixture into a watering can and add 1 gallon of water. Sprinkle onto containers and flower beds where animal damage is occurring, or pour it directly onto mole tunnels. Reapply after heavy rains.

Planning an Animal-Resistant Garden

Barbara Pleasant

If you are one of the thousands of gardeners who live in an area where deer and rabbit populations are high, you know too well the heartbreak of looking out your window in the morning to find that your garden has been ravaged during the night. You cannot control what wild animals do while you sleep, but can design a landscape that offers little in the way of attractive foods. As for those plants that rabbits and deer love—such as most fruits and vegetables—the best solution is to fence in the area where you plan to grow your own produce.

Where rabbits are the primary problem, you can install a dependable rabbit fence in a matter of hours. Deer, in comparison, have no trouble leaping over a 6-foot-tall fence, and if they are hungry enough, they will barrel through an electric fence as well. Still, electric fencing is relatively inexpensive and easy to install. Do check your local zoning laws before you start; for safety reasons, some communities restrict electric fence use by homeowners. If you do install an electric fence, post appropriate warning signs and make your neighbors aware of the fence's location.

There is another option—7½-foot-tall black plastic mesh fencing, which is sold by companies that specialize in deer-resistant garden supplies. Plastic mesh fencing's light weight

Continued →

makes it easy to install, and it requires few fence posts to hold it in place. The mesh is nearly invisible at even a relatively short distance, so it doesn't impede landscape views. Deer have a hard time seeing it, too, and are usually so spooked when they run into it that they don't return for a second encounter.

Working with Animal Resistant Plants

You can fence in your food garden, but what about the rest of your landscape? Although rabbit and deer appetites vary with season and region, the plants listed on page 834 in "60 Animal-Resistant Plants" are generally unattractive to rabbits, deer, and even squirrels. If you use large numbers of these plants, animals will gradually lose interest in your yard, and you can begin slipping in favorite plants here and there, where their presence will be camouflaged by plenty of neighboring plants animals find distasteful.

For best results, plant nothing but animal-resistant plants around the perimeter of your yard. If you know the direction from which animals tend to enter your property, barriers of thorny blackberries and unpalatable plants may turn them away.

Many of the plants that resist deer and rabbits are also poisonous to people, so take this into consideration if you share your garden with curious kids. Fencing in your edible plants and growing herbs in their own special area make it easy to teach kids the difference between safe and toxic plants.

Build a Fence That Bugs Bunnies

Bunnies frolicking in your yard on a summer evening make a charming sight, but it's much harder to romanticize their company when you find your lettuce nibbled down to nubbins, and nothing but stubs where your beans used to be. Scent repellents may have some effect in keeping Peter Cottontail and pals out of your garden, but you have to be rigorous in refreshing them after every rainfall. Even then, they may not do the trick once critters have discovered the goodies in your garden.

It's easy to install a basic fence that will keep rabbits—and groundhogs—from using your garden as their own personal salad bar. The fence doesn't have to be tall—18 to 24 inches is usually enough—but it does need to extend underground. There is also good reason to allow the top of the fence to remain loose and somewhat floppy. Should a raccoon or other climbing animal try to scale the fence, the wire will naturally curl backward toward the animal, making the fence much more difficult to climb. Leaving the top edge unattached also makes it easier to step over when you're carrying tools or harvested vegetables. Although this fence does include a section that can be opened when you need to get inside with a wheelbarrow, you will usually come and go by simply stepping over the fence.

If you want to camouflage the fence, you can do so with handmade wattle panels. Or, you can use a low picket fence, which is easy to install using preassembled panels.

You Will Need

Tools: Garden spade or trenching spade, mallet, hammer, sturdy gloves, wire cutters

48-inch-tall wood or metal fence posts, 1 for each corner, plus one for every 4 feet of fencing

36-inch-wide chicken wire (also called poultry netting) to enclose the perimeter of your garden

Wire or plastic cable ties for fastening chicken wire to posts, 3 for each post

Two 24-inch-long pieces of 1 x 2 furring strip

Four 1½-inch nails

Two short bungee cords (utility tie-downs)

1. Dig a 6-inch-deep trench around the perimeter of your garden using the garden spade or trenching spade.

2. Use the mallet or hammer to set the posts in the trench, first at the corners of the garden and then at 4-foot intervals in between. Pound them in 8 inches deeper than the bottom of the trench. If necessary, make guide holes for the posts with a rebar stake.

3. Unroll the chicken wire and stretch it between the posts along one side of the garden, aligning the bottom edge of the wire with the bottom of the trench. Use wire or plastic cable ties to fasten the chicken wire to the posts in three places—1 inch, 13 inches, and 25 inches above the soil. Do not attach the top edge of the chicken wire to the posts.

4. Repeat Step 3 with the remaining sides of the garden. When you reach the section between the last post and corner, cut the chicken wire to the proper length, and reinforce the cut edge with the furring strips. Lay the cut edge on the ground, and sandwich the edge of the chicken wire between the two furring strips, with the tops of the furring strips 6 inches from the top edge of the chicken wire. Nail them together.

5. To make a convenient opening in the fence, make an 8-inch-long vertical cut in the chicken wire 4 feet from the last corner post. Roll up the lowest 6 inches of chicken wire between the cut and the furring strips so it will not be buried. Fasten the reinforced end of the fence to the last corner posts with bungee cords.

6. Before refilling the trench, angle the bottom edge of the chicken wire outward, so that any animal trying to dig under the fence will be almost standing on top of the wire as it digs. Refill the trench with soil, and pack it down firmly.

Make an Animal Tracking Box

You know you have an animal pest making secret visits to your garden, but you have yet to catch a glimpse of your wild visitor. Many animals are nocturnal, but you don't have to stay up all night waiting to see who shows up. Instead, make a simple tracking box, and study the footprints the animal leaves behind.

You Will Need

Tools: Utility knife, scissors, watering can

1 waxed cardboard box

1 roll of duct tape

3 gallons of clean sand

1. Use the utility knife to cut around the sides of the box, removing all but the bottom and 3 inches along all four sides. Use the duct tape to reinforce the box by taping across the bottom in both directions. Also wrap tape around all of the sides and corners of the box.
2. Fill the prepared box almost to the top with clean, dry sand. Place it where animal activity is likely, and sprinkle the sand with water until it is lightly moist. Pat the surface level with your hand. Press your hand lightly to see if it leaves a print. If needed, add more water to the sand and smooth it again.
3. Check the box for prints first thing in the morning. Use the toe-counting method to narrow the field of possibilities.
   - Four toes on both the front and back feet, with a fifth central pad, are signs of an animal in the dog, cat, or rabbit family. Dog tracks usually include claw marks, while those of cats do not. Rabbit tracks are elongated, with toe marks barely visible.
   - Four toes on the front feet and five toes on the back suggest some type of rodent, such as mice, squirrels, chipmunks, or woodchucks.
   - Five toes on all four feet are evidence of the raccoon family, which includes weasels, skunks, opossums, and raccoons. The tracks resemble the shape of a small human hand.
   - Two elongated toes are proof of a visit by deer, elk, or moose.

Make a No-Dig Barrier

Whether you want to foil cats intent on digging up newly planted carrots or squirrels after your tulip bulbs, a wire barrier will do the trick. As long as these and other animals can't get their paws into soft, freshly dug soil, your work won't be ruined. You can leave the barriers in place as long as you like. If digging mice and squirrels are a problem all winter, it's best to provide protection for bulbs until spring, when other foods become available. You can hide the wire barriers from view by covering them with a thin layer of chopped leaves or other organic mulch.

You Will Need

Tools: Sturdy gloves, wire cutters or tin snips, scissors

Chicken wire (also called poultry netting)

1 wire clothes hanger

1 yard of colorful ribbon or yarn

1. Wearing gloves to protect your hands, use the wire cutters or tin snips to cut a piece of chicken wire large enough to cover the area where your seeds or bulbs are planted. Lay it on top of the soil, and bend the edges down so they stick into the soil.
2. To make staples to secure the chicken wire in place, use the wire cutters or tin snips to cut off the two corners of the clothes hanger, 5 inches from the corners. Bend the ends in until the sides are parallel.
3. Bend the two wires attached to the hanger's hook downward until the ends are parallel. Bend the remaining straight piece of wire into a U-shape.
4. Pin down the four corners of the chicken wire with the wire staples. Tie a 9-inch piece of ribbon or yarn to each staple to make them easy to find.

Bird-Deterrent Basics

Barbara Pleasant

Most gardeners regard birds as friends rather than foes, but large numbers of crows, blackbirds, jays, and even mockingbirds can become a nuisance when they discover your seeds, seedlings, or almost-ripe berries. Birds are quick to grow accustomed to the devices gardeners use to try to scare them away, so success at protecting your garden from bird damage requires a multifaceted approach.

Use motion. Whirligigs, wind socks, compact discs dangling on strings, or other devices that wiggle or wave will help keep birds wondering if the objects are alive and, therefore, if they should avoid them. Relocate these devices regularly, before birds figure out that they are actually harmless. Reflective foil tape moves

Continued ➔

in the wind, so it makes a good deterrent for tomatoes, berry bushes, and other plants that need protection for several weeks.

Use color. Put brightly colored pinwheels and flags around your garden to take advantage of birds' color vision. Some gardeners use colorful stuffed animals, purchased at yard sales, to populate their gardens with curious, colorful "predators."

Use sound. Things that make noise help to keep birds away, too. Just be careful to avoid noisemakers that drive you and your neighbors bonkers in the process. Try wind chimes or similar unobtrusive and unpredictable sound sources. One old-fashioned method that works well in windy areas is to bury empty soda bottles around the garden, with their open mouths 2 inches above the soil line. As wind blows over the bottles, it creates an eerie song that spooks birds. You can also try playing

60 Animal-Resistant Plants

15 Perennials Rabbits and Deer Usually Don't Eat

- Butterfly weed (*Asclepias tuberosa*)
- Coral bells (*Heuchera americana*)
- Ferns (many species)
- Foxgloves (*Digitalis* spp.)
- Goat's beard (*Aruncus dioicus*)
- Goldenrods (*Solidago* spp.)
- Hardy geranium (*Geranium maculatum*)
- Hellebores (*Helleborus* spp.)
- Irises (*Iris* spp.)
- Joe-Pye weeds (*Eupatorium* spp.)
- Lamb's ears (*Stachys byzantina*)

- Thyme (*Thymus* spp.)

12 Animal-Resistant Flowering Shrubs

- Abelia (*Abelia grandiflora*)
- Blue mist shrub (*Caryopteris clandonensis*)
- Bridal wreath spiraea (*Spiraea* spp.)
- Butterfly bush (*Buddleia davidii*)
- Currants (*Ribes* spp.)
- Daphne (*Daphne* spp.)
- Forsythia (*Forsythia x intermedia*)
- Grape holly (*Mahonia* spp.)
- Holly (*Ilex* spp.)
- Lilac (*Syringa* spp.)
- Rose of Sharon (*Hibiscus syriacus*)
- Viburnum (*Viburnum* spp.)

8 Deer-Resistant Evergreen Trees and Shrubs

- Chinese holly (*Ilex cornuta*)
- Common boxwood (*Buxus sempervirens*)
- Fraser fir (*Abies fraseri*)
- Junipers (*Juniperus* spp.)
- Mountain pine (*Pinus mugo*)
- Norway spruce (*Picea abies*)
- Scots pine (*Pinus sylvestris*)
- White spruce (*Picea glauca*)

10 Bulbs Squirrels (Usually) Won't Bite

- Autumn crocus (*Colchicum* spp.)
- Crown imperial, checker lilies (*Fritillaria* spp.)
- Daffodils, narcissus (*Narcissus* spp.)
- Glory of the snow (*Chionodoxa* spp.)
- Grape hyacinths (*Muscari* spp.)
- Grecian windflower (*Anemone blanda*)
- Hyacinths (*Hyacinthus* spp.)
- Ornamental alliums (*Allium* spp.)
- Squills, scillas (*Scilla* spp.)
- Surprise lilies (*Lycoris* spp.)

a battery-operated radio in the part of your garden you want to protect. Change the station each day so birds don't become too accustomed to the sound.

Use danger. Scarecrows and other things that look like threats—including rubber snakes, plastic owls, or reflective balloons—will make birds think twice about dining in your garden. Be sure to change the location of your scare devices often enough to convince birds they are real.

Use netting. Birds that are too smart or persistent for other methods can be kept from raiding the garden with plastic bird netting. Some birds will reach through netting that is draped over plants, so it's best to attach the netting to posts to create a few inches of space between the netting and the plants. Use clothespins to gather the edges of the netting together, and to secure it to strings tied between the posts.

Five Fine Pest Barriers

Barbara Pleasant

Faced with unexpected pest problems, creative gardeners have come up with a long list of easy-to-make barriers. The more you garden, the more you will probably invent solutions to pest challenges. Like the ones described here, they may surprise you with their simplicity—and with how well they work.

Milk Jug Melon Cradles

Protect developing melons from mice and mold. Cut a 1-gallon plastic milk jug in half vertically, and then use an ice pick to punch three or four drainage holes in each half. Slip a prepared cradle beneath a growing melon or winter squash. The plastic cradle will create enough of a barrier to protect the fruit from nibbling mice and other determined varmints, and it will also reduce the risk of rot due to soil-dwelling fungi and bacteria.

Bag Up Your Corn

If you think that raccoons or crows are watching your sweet corn for signs of ripening, beat them to the punch by covering almost-ripe ears with small paper bags (such as lunch bags) fastened in place with clothespins or rubber bands.

Make Flea Beetle Teepees

If you grow eggplant, you've seen the tiny jumping flea beetles that chew hundreds of holes in eggplant leaves. Flea beetles often move to eggplant from early potatoes, or from horse nettle, a common host weed. To keep them off your eggplant, make a teepee around the plants with several sticks fastened together at the top with string, and cover the structure with scraps of rowcover or a piece of cheesecloth. Either can be held in place with clothespins.

Bubble Wrap Barrier

Broccoli, cauliflower, and other cabbage family cousins often thrive in the fall garden—if you can keep them safe from cabbage root maggots, the larvae of a fast-moving fly. To frustrate these flies, surround each seedling with a mat that covers the root zone and fits snugly around the stem. Tar paper is a popular choice, or you can use bubble wrap. Cut either material into a 10-inch-wide circle, cut a slit from one edge to the center, and place it around seedlings right after transplanting.

Stick Squirrel Barrier

In a good acorn year, squirrels are eager to hide their treasures everywhere, including in large containers left outdoors through the winter. Keep hardy plants safe from squirrel digging by covering your pots with a simple barrier woven from sticks. Collect a dozen or so sticks a few inches longer than the diameter of your pot, and weave them together, waffle-style, on a flat surface. Then go back and tie the joints together with string. Place the barrier over the soil in your containers.

Your Seasonal Pest-Fighting Calendar

Now you've learned all about the different types of insect and animal pests that might visit your garden and how to control them. Here's what you should be doing each month of the year to help protect your garden from these creatures and critters.

That's where this handy calendar comes in. It lists helpful hints that you can use even during the months when you're not growing anything in your beds—so that you get the better of pests, and not the other way around.

January

Winter isn't too early to start thinking about pest control. You can:

- Figure out a rotation plan for your vegetable beds so that you're not growing the same plant family in the same location each year.
- Make a list of pollen- and nectar-providing plants, such as alyssum and goldenrod, that you can incorporate into your beds to attract beneficials.
- Research what pest problems are common in your area and how you can control them organically.

February

Finalize what you want to plant this year. If you're buying seeds or plants through mail-order catalogs, try to choose varieties with resistance to pests that are common in your area. Consider fencing your garden if you have a serious problem with groundhogs and rabbits.

Continued →

March

With warmer weather just around the corner, now is the time to

- Check out the condition of your garden soil; healthy plants are much less likely to be attacked by pests.
- Add compost to your beds, and make sure they have good drainage.
- Choose appropriate sites for your plants (for example, make sure shade lovers aren't growing in full sun) to give them the opportunity to thrive.
- Put up birdhouses and bat houses around your property to encourage these pest-eating creatures.
- Prune diseased wood out of fruit trees and shrubs to make them less inviting homes to pests.

April

Mulch garden beds with grass, hay, wood chips, or other organic materials to suppress weeds. Begin patrolling your garden to learn what pests and beneficials are residing there. Give that cracked clay flowerpot a second life as a toad house in your garden. Inspect any plants you buy to make sure they're free of insects.

May

Put row covers on seedlings after you plant them to prevent insect pest damage, such as flea beetles on eggplant and cabbage loopers on broccoli and cabbage. Sink shallow dishes of beer into the soil around your beds to lure slugs to their demise.

June

Although you may take vacation time during summer, pests stay hard at work. So this month:

- Time your vegetable plantings to avoid the worst pests.
- Watch for aphid colonies on lush young growth, and use a heavy stream of water or a soap spray to reduce their populations.
- Handpick pest insects.
- Pick up damaged fruit off the ground so it's not inviting to insect and animal pests.
- Use a summer oil spray if spider mites, scale, or mealybugs are a big problem on trees and shrubs.

July

Your garden is in full swing now, producing juicy tomatoes and luscious peppers—inviting snacks for insect and animal pests. Remember to:

- Continue patrolling your garden and hand-picking insect pests.
- Spread ground black pepper or chili powder around your beds to repel hungry rabbits. If you have a dog, let him police your garden to help scare rabbits away.
- Hang old nylon stockings filled with cat or dog hair around plants that deer like to eat.

August

Continue to patrol the garden for pest problems and pull out weeds and diseased plants. Enjoy the harvest as summer starts to fade away.

September

Take notes on which varieties did well in your garden and which were prone to pest problems. Also make notes on which beneficials visited your garden; that way, you can be sure to grow plants next year that will attract them.

October

Remove mulch from around the base of fruit trees to discourage mice from nesting there and nibbling on root systems. Put hardware cloth tree guards around young trees to prevent mice and rabbits from eating the bark.

November

Now that the growing season is pretty much over, it's time to ready your garden for winter.

- Clean up any remaining spent vegetable plants for the winter and compost the debris (except for diseased plants, which you should dispose of).
- Be sure to leave spent perennials in your beds so overwintering beneficials will have someplace to live during the cold months.
- Mulch perennial and strawberry beds with a layer of straw to prevent winter injury.

December

Hang strong-scented soap bars in trees and shrubs to deter deer. Put up feeders for your feathered friends. Relax by the fire with a good book, and dream about warmer days ahead.

Terrify Them with Technology

Roger Yepsen

The surest weapon for scaring off the animals that prey on the garden is you, the gardener. But you can't be out there waving your arms at all hours of the day and night. And while the folksy form of a scarecrow is a quaint sight, it's not apt to be intimidating to animals for long. Instead, consider buying a Scarecrow, a clever battery-powered device that's attached to the end of a garden hose. It detects movement (caution: any creature's movement, gardener included) and directs a blast of water in that direction.

Pest Glossary

Abdomen. The last section of an insect's body, following the head and thorax. Digestive and reproductive organs are found in the abdomen.

Antenna. Paired, segmented structures, also called feelers. One on each side of the head. Aid sensory perception. Plural antennae.

Bacteria. A single-celled microorganism that reproduces by simple cell division. Beneficial bacteria can help control insect pests, but some bacteria species can cause serious plant diseases, like bacterial wilt and fire blight.

Beak. Long mouthpart used by sucking insects to pierce the surface of a plant or animal. Hollow and jointed. One or more tiny needles in the beak pierce the tissue.

Beneficials. Helpful creatures—birds, bats, toads, snakes, spiders, and predatory insects—that eat garden pests.

Biological controls. Pest-control measures that use living organisms to fight other living organisms. Examples include releasing and attracting natural insect predators and parasites and using microbial sprays to control insects and diseases.

BT. *Bacillus thuringiensis.* A spray derived from naturally occurring bacteria that kill certain insect larvae.

BTK. A BT variety (*B. thuringiensis* var. *kurstaki*) that controls cabbage loopers, cabbageworms, tomato hornworms, fruitworms, European corn borers, and pest larvae.

Caterpillar. Larval stage of a butterfly or moth. Segmented or wormlike, with a distinct head, 12 simple eyes, a pair of very short antennae, and usually six well-developed legs, as well as two to five pairs of prolegs.

Chrysalis. The tubular, hard pupal shell of a butterfly.

Cocoon. The silken pupal case of a butterfly or moth.

Companion planting. Combinations of plants that work well together to repel pests, attract beneficial insects, or make efficient use of garden bed space.

Compost. Decomposed and partially decomposed organic matter (such as kitchen scraps, leaves, grass clippings, dead plants) that is dark in color and crumbly in texture. Used as an amendment, compost increases the water-holding capacity of the soil and is an excellent nutrient source for microorganisms, which later release nutrients to your plants.

Composting. The art and science of combining organic material so that the original raw ingredients are transformed into compost.

Compost tea. A fertilizer made by soaking a cloth bag full of compost in a watering can or barrel for several days.

Compound eye. Eye of an insect, composed of separate, close-fitting hexagonal lenses. Sensitive to movement and color. Larvae lack compound eyes.

Crop rotation. Rotating crops from different botanical families to avoid or reduce problems with soilborne diseases or soil insects.

Cultural controls. These are gardening practices that reduce pest problems and include building organically enriched, biologically active soil, selecting well-adapted disease-resistant varieties, keeping the garden clean, and practicing crop rotation.

Dormant. Inactive; in suspended animation; hibernating. Dormancy occurs in winter.

Dormant oil. A heavy petroleum oil that can be sprayed on dormant orchard trees and ornamental plants to control overwintering stages of mites, scales, aphids, and other insects. See also Summer oil.

Exoskeleton. The hard outer covering or skeleton that protects an insect's body like armor. Forms a jointed frame.

Frass. The sawdustlike excrement of borers, such as the peachtree borer and squash vine borer.

Fungi. A generally beneficial spore-producing organism that helps the decomposition process. Fungi also cause many common plant diseases such as powdery mildew and late blight.

Grub. The larva of a beetle. Grubs are plump, flat, or wormlike, with well-developed heads and 3 pairs of legs. They pupate in the soil or other protected sites.

Hibernation. A winter period of suspended animation passed by many insects that live more than one season. Usually spent in soil or garden debris.

Honeydew. A sweet, sticky substance secreted by aphids as they feed. Honeydew allows sooty mold to grow on leaves.

Horticultural oils. See Dormant oil; Summer oil.

Host. A plant or animal that a parasite or pathogen depends on for sustenance.

Insecticidal soap. Specially formulated solutions of fatty acids that kill insect pests like aphids, mites, and whiteflies.

Instar. The form of an insect between each molt. Most insects pass through three to six instars.

Larva. An immature stage of an insect.

Maggot. The larva of a fly, usually a small, white, legless worm without an obvious head. Mouthparts are hooked.

Milky disease spores. A microbial insecticide that kills Japanese beetle grubs.

Molt. A shedding of the exoskeleton so that an insect can grow. The old skin splits after a new one has formed beneath it.

Continued →

Nematode. A microscopic, unsegmented, threadlike worm; some nematodes are beneficial, while others can harm plants.

Nymph. An immature stage of an insect that doesn't form a pupa.

Organic matter. Materials that are derived directly from plants or animals. Organic gardeners use plant and animal by-products to maintain soil and plant health and don't rely on synthetically made fertilizers, herbicides, or pesticides.

Organic pest management. An approach to pest control that combines cultural, biological, and physical measures to prevent problems or to keep them in check.

Parasite. An insect that lives and feeds in or on another insect or animal for at least part of its life cycle.

Pathogen. An organism that causes disease. Pesticide. Any substance, synthetic or natural, that is used to kill insects, animals, fungi, bacteria, or weeds.

Pheromone. A chemical substance, such as a sexual attractant, secreted by an insect to create a response in others of its species.

Pheromone traps. Insect traps that work by attracting male insects to the scent of breeding female insects. These traps are available for a variety of flying pests, including cabbage loopers, Japanese beetles, and peachtree borers. The traps work best in large areas or orchids.

Physical controls. Control measures that prevent pests from reaching your plants or remove them if they do. Barriers, traps, and hand-picking are physical controls.

Predator. An insect that feeds on another live insect or animal.

Pupa. A hardened shell formed by a larva, within which the adult stage develops.

Row covers. Sheets of lightweight, permeable material, usually polypropylene or polyester, that can be laid loosely on top of plants to act as a barrier to insect pests or that can give a few degrees of frost protection at the beginning or end of the growing season

Scavenger. An insect that feeds on dead plants, animals, or decaying matter.

Spiracle. One of many tiny holes in the thorax and abdomen of an insect that serve as breathing pores.

Summer oil. A light petroleum oil that controls aphids, mealybugs, spider mites, scales, and some caterpillars. For use on ornamentals. See also Dormant oil.

Thorax. The center section of an insect's body, between the head and the abdomen. Wings and legs are attached to the thorax.

Trap crops. Plants you grow to lure pests away from other crops in your beds. For example, dill lures tomato hornworms away from tomatoes.

Virus. Microscopic organisms that must be inside the living cell of a host to reproduce. Viruses can be transmitted by insects, mites, and nematodes as well as through contact with garden tools and plant cuttings.

Viviparous. Bearing live young. Aphids can be viviparous.

Jeff and Liz Ball

Most of the insects you see in the flower garden are either harmless, adding a little color and diversity to the garden without threatening your plants, or beneficial, pollinating your flowers or eating pests. However, pest insects do visit the flower garden. Most of the time, their damage level is acceptable—you'd have to crawl within inches of your plants to see the few holes in the leaves. In these cases, the best policy is live and let live: Spraying would just disrupt the natural balance (which, after all, is keeping things under control) and waste your time and money. If you're threatened with an invasion, however, or if pests are making your garden look ragged and unsightly, it's time to reach for the controls.

Fortunately, flower gardeners have a variety of safe and effective controls for insect pests in the backyard. New botanicals, biologicals, and traps are being researched, tested, and marketed on a regular basis. Because more and more of these controls are effective only on one pest or a related group, and even broad-spectrum botanicals often work better on some pests than others, "know thine enemy" is the relevant commandment here. Identify your problem pest—then choose the appropriate control. An understanding of insects in general and how they identify and feed on various flowers will give you a better idea of how to use natural pesticides most effectively. (If it's a stomach poison, for example, you'll have to apply it to parts of the plant that the pest will eat.)

Of course, many of the pest problems you face in the flower garden can be prevented before they develop. The first line of defense is the plant's own built-in protections. If certain pests become problems almost every year, choose resistant cultivars whenever they're available. (Catalogs usually mention pest or disease resistance in their plant descriptions, and you can often

get a listing from your cooperative extension agent.) By following good gardening practices and giving plants the care they need, you'll encourage all your plants' natural resistance to pests.

Insects themselves—the beneficial allies that prey on or parasitize pests—are your second line of defense. For that reason, there is no need to kill off every last pest insect on your property. The beneficial predators need some food to encourage them to stay around. A healthy balance of beneficial and pest insects tends to keep outbreaks under control.

Despite our best preventive efforts, however, occasionally pest insects appear in overwhelming numbers. At such times, the third line of defense is an environmentally safe pesticide. Many biological and botanical pesticides, as well as organic controls such as insecticidal soap and diatomaceous earth, are now available at garden centers and through mail order.

The best approach to pest control in the flower garden is a well-rounded strategy that includes good garden practices, prevention, and, when needed, safe controls. With such an approach, your garden can be beautiful and comparatively problem-free year after year.

Identifying the Pest

Obviously, identification of invading insect pests is the key to successful prevention and control. Develop the habit of observing the leaves and buds of your flowering plants closely. As you become familiar with the look of the plant, you will be able to see symptoms of pest infestation as soon as they develop. Knowledge of characteristic symptoms will make it easier to identify the insect culprit. Then you can plan a control strategy.

LOOK FOR SYMPTOMS

The signs of insect attack are easily recognized, although a few may resemble disease symptoms. Some of the most common symptoms of insect pest attack include the following:

- Leaves chewed from the outside edge
- Holes chewed in the leaves
- Complete defoliation of the plant
- Leaves wilted and discolored
- Discolored speckles on the leaves
- Leaves curled or puckered

Once you are alerted to the possibility of an insect pest problem, examine the affected plant for the culprit itself. In most cases, insect pests attack the plant's tender new growth, so look there first. Check the upper leaf surfaces, then the undersides of the leaves (where most insects and their eggs are located), and finally, the point where leaves attach themselves to the stem. Examine the buds and flowers. Although pests can also strike roots, and many pests—such as the dreaded slug—work at night, this daytime search will reveal most of the common culprits.

There are a number of good books for identifying pest insects. *Rodale's Color Handbook of Garden Insects*; *Rodale's Garden Insect, Disease, and Weed Identification Guide*; *The Healthy Garden Handbook*; and *The Golden Guide to Insect Pests* are particularly easy to use.

Controlling Insect Pests

When you have found a pest or its damage, the next step is determining an effective control. Your goal is to suppress pest populations before they do measurable harm to the flower garden.

Traps and Mechanical Controls

Before you reach for sprays or dusts, even though they might be comparatively harmless botanical or biological controls, consider trapping or some other physical means of removing insect pests from plants. Often these solutions to the problem are the safest, surest, and least expensive.

Cover Traps

Some pests seek protection from the hot sun during daylight hours. Trap them by offering a simple piece of board or a length of empty garden hose for shelter. Slugs happily crawl under boards, and earwigs readily crawl into a piece of garden hose. Check these traps twice a day and discard any inhabitants in a can of water containing a little kerosene or soap.

Handpicking

Handpicking, though not for the squeamish, is one of the oldest methods of safe and effective insect control. Used in the early stages of infestation, it can forestall a population explosion. Pick off pests and squash them between your fingers, or just drop them in a can of kerosene or soapy water. Wear tight-fitting rubber gloves if you don't like the idea of handling insects.

Locating insects and then handpicking them is slow work. To speed things up, spray water on the plants. Disgruntled pests will crawl from their wet hiding places to the tops of the plants, where it's easier to pick them.

Sticky Traps

Sticky traps can be used to cut down on aphid and whitefly numbers. You can purchase them or make your own. To make a trap, take a 10" x 10" piece of Masonite or other sturdy material that is colored school bus yellow and cover it with something sticky such as Tangle-Trap, TackTrap, Stickem, glycerine, motor oil, or petroleum jelly. Hang the traps so that they are adjacent to, but not above, susceptible plants, or attach them to stakes. Clean and recoat them periodically.

Water Spray

A forceful water spray will take care of some pests by itself. Drench infested plants with a hose, targeting the undersides of leaves where many insects live and lay their eggs. Aphids

Continued →

and spider mites can be controlled this way. Spraying plants with water several days in succession will disrupt the pests' breeding and hatching cycles and can eliminate the population altogether.

Spray plants early in the morning. Use a hose with a nozzle that emits a fine spray of water. Turn the water on high and thoroughly spray the infested plant. Spray at least twice more, either three days in a row or every other day. This will wash off the pests that are already feeding on your plants and eliminate their eggs.

NATURAL SPRAYS AND DUSTS

If handpicking and mechanical controls are not effective, try a spray or dust to get rid of insect pests. Most products can be applied in either form, but sprays are a little easier to use and generally provide more thorough and even coverage than dusts. You can use virtually any type of sprayer, from a plastic, hand-held bottle to a large garden sprayer, depending on the size of the plant or the garden area you need to cover. Listed below are several different types of sprays and dusts, with details on how to use them.

Insecticidal Soap

Insecticidal soaps, such as Safer's, are now widely available commercially. They have been specially formulated to kill certain pest insects, while sparing beneficial insects. Insecticidal soap is biodegradable and breaks down within 7 to 14 days, so it does not harm plants or the environment. It is safe to use around animals and people. While homemade soap sprays might be effective, only commercial soap spray is recommended for uniform performance. It is easy to use and is effective against many insect pests, including aphids, spider mites, and whiteflies.

If you are dealing with a heavy infestation, spray affected plants every two to three days for two weeks. Set the sprayer for medium droplet size and strong pressure to thoroughly wet all surfaces of the plant from top to bottom. Insecticidal soap is a contact insecticide, so it must directly contact the insect to be effective. Take care to spray the undersides of leaves, where you will find most of the pests.

Insecticidal Soap and Alcohol

Increase the effectiveness of insecticidal soap by mixing it with isopropyl alcohol. Make this mix by adding a tablespoon of alcohol for each pint of insecticidal soap solution. Alcohol alone can burn plants, but diluted in the soap spray, it penetrates an insect's waxy protective coating and carries the pesticide with it, bringing it in direct contact with the insect's body.

Garlic Spray

We're all cautious about eating garlic or onions when we're in the company of others, fearful that those we're talking with will turn and walk away at the smell of garlic breath. Apparently garlic has that effect on pest insects, too. Homemade sprays from garlic, onions, or chives have been found to effectively repel certain insect pests. To make the spray, mix ½ cup of finely chopped garlic cloves, onions, or chives with 1 pint of water; then strain out the particles and spray.

Researchers are working on a more potent brew made by soaking 10 to 15 finely minced garlic cloves in a pint of mineral oil for at least 24 hours. The oil is then strained. Two teaspoons of the oil are mixed with a quart of insecticidal soap solution and applied to infested plants. Some tests show the soap spray's effectiveness has been greatly improved by the garlic oil, even on pests not normally killed by the soap alone. However, the true effectiveness of this spray is still undetermined.

Diatomaceous Earth

Diatomaceous earth (often called D.E.) keeps pests from plants in the same way that hot coals would prevent most people from walking up to something. Diatomaceous earth is a powder made from the fossilized skeletons of diatoms—microscopic sea creatures composed primarily of silica. The granules of this fine powder are soft to us, but to insects they are very sharp; they cut the bodies of soft-bodied pests such as caterpillars on contact, causing them to dehydrate and die. D.E. is effective against aphids, caterpillars (including cutworms), fly maggots, grubs, mites, slugs, and the like. It does not harm earthworms.

When you buy D.E., make sure that it's designated for agricultural use, not for use in swimming pool filters. To apply, dust D.E. around the base of plants in the late evening, ideally after a light rain or after plants have been sprayed with a fine mist of water. Dust progressively upward from the ground, covering stems and leaves, especially the undersides of leaves. You can also spray it on plants. Put ¼ pound D.E. in a 5-gallon sprayer. Add 1 teaspoon of flax soap (available from paint supply stores) or insecticidal soap concentrate in a quart of warm water, then add more water, enough to make 5 gallons. Mix the solution well. Reapply after rain.

BIOLOGICAL CONTROLS

The variety of beneficial insects, bacteria, and viruses that already reside in your yard will help protect your flowering plants from pest insects. Perhaps the best known of the biological controls are the predatory and parasitic insects that attack and destroy pests. There are also microscopic creatures—the viruses and bacteria—that are more than willing to enlist in your war against the troublesome insects in your flower garden. Two that are readily available for use against flower pests are Bt (*Bacillus thuringiensis*) and milky spore disease (*Bacillus popilliae*).

Bt (*Bacillus thuringiensis*)

Bt is a naturally occurring parasitic bacterium that attacks leaf-eating caterpillars. It invades their digestive systems and

kills them within 24 hours. You can purchase commercially prepared Bt under a number of trade names, including Bactur, Biotrol, Dipel, and Thuricide. Bt is sold in both powder and liquid forms. The powder may be applied as a dust or diluted with water and sprayed on plants. The liquid is usually concentrated and should be diluted with water according to package instructions. The liquid Bt can only be stored for a year; in effect, you need to replace it each season. Stored in the container in a cool, dark place, powdered Bt will remain viable for three to five years.

Because Bt kills all caterpillars, it's important to make sure that you've got a problem before you apply it. Otherwise, you could kill the beautiful butterflies and lovely nocturnal moths that add such delight to the summer garden. Try to identify the moths and butterflies hovering over your flowers; most are colorful and harmless. Make sure you're not destroying the parsleyworm that tomorrow might be a gorgeous black swallowtail. If caterpillars are causing unsightly damage—say, if corn earworms are eating holes in your ageratum foliage or leaf tiers are rolling your forget-me-not leaves—try handpicking before resorting to Bt. If you're confronted by a major infestation or have too many plants to handpick, Bt is an effective control.

The timing of Bt applications is critical because it must be eaten by the caterpillars to be effective. Generally, caterpillars are most active in the spring and late summer. Observe your plants closely during these times, and as soon as you see destructive caterpillars beginning to feed, spray or dust plants with Bt. Thoroughly cover all parts of the plant leaves, especially the undersides. When using the powdered form of Bt, wet plants before you dust them. Dusting the undersurfaces as well as the top surfaces of leaves keeps Bt active longer because the bacteria survive longer out of direct sunlight. Reapply the dust after each rain.

To make a foliar spray from powdered Bt, follow the directions on the container. Spray infested plants every 10 to 14 days until the pest is under control. To help the diluted powder adhere to plant leaves, add 1 tablespoon of fish emulsion to each gallon of spray. A little commercial insecticidal soap or light horticultural oil also works as an adherent. The liquid concentrate formulation of Bt adheres well to plants.

Keep in mind that Bt breaks down in sunlight. The powdered form remains viable for only seven days after application, and the liquid spray form for just 24 hours. Apply Bt each year as the pest caterpillars emerge.

Milky Spore Disease (*Bacillus popilliae*)

Like Bt, milky spore disease is a bacterial disease. It is applied to lawns to control beetle grubs—specifically, the white grubs of the Japanese beetle, a major pest of roses and other flowers. Milky spore takes 2 to 3 years to provide complete control of grubs, but it continues to be effective for up to 20 years, so that a single application provides long-term control. It is sold as a dust, in granular form, or as a wettable powder under the trade names Doom and Grub Attack. Apply in spring or fall, when grubs are most active. Because beetles can emerge from surrounding lawns and migrate to your flowers, you'll get best control if your neighbors apply milky spore to their lawns when you treat yours. Unused milky spore remains viable for several years.

THE LAST RESORT—BOTANICAL POISONS

In spite of every precaution, sometimes pest insects overwhelm a flower bed. In these cases, the traps, sprays, and other methods discussed above can't control the situation fast enough and prized flowers are threatened. Under these rare circumstances, it may be necessary to resort to the last line of defense—the botanical poisons. These products include pyrethrum, rotenone, ryania, and sabadilla. Although these poisons have been extracted from various plants and are, therefore, natural substances, they are deadly to all insects. They will kill off the pest insects that infest your plants, but they will also kill nearby beneficial insects, including honeybees. These products require careful handling for user safety, as well. Use them as a last resort in situations where there is no alternative. Because these products do break down quickly, they do not pose a significant threat to the environment.

Minimize the impact of botanical poisons by using them carefully. If a botanical poison is necessary while honeybees are pollinating, use pyrethrum rather than rotenone, and spray at dusk, when bees are least active. Even though it's more toxic to bees, pyrethrum breaks down more quickly—within 6 hours if the temperature is 55°F or higher. Foliar sprays of either pyrethrum or ryania are less toxic to bees than dusts. If a heavy dew is predicted, do not spray; the insecticide will not break down before the bees begin feeding in the morning.

Pyrethrum

Made from the crushed dried flowers of the painted or pyrethrum daisy (*Chrysanthemum cinerariifolium*), pyrethrum paralyzes many insects on contact. It acts quickly, passing directly through the skin of the insect and disrupting its nerve centers. The insect becomes disoriented and stunned. However, if an insect receives less than a lethal dose, it will revive completely. Pyrethrum residues do not persist in the environment, and their impact on pests lasts only 6 hours. It must contact the insect directly to be effective. Usually, two applications to the threatened plant, three to four days apart, will successfully control a pest problem. Apply pyrethrum in the evening to avoid killing bees, and don't use it near streams or ponds—it's toxic to fish.

Do not confuse this botanical insecticide with synthetic pyrethrins, like allethrin, or with the synthetic pyrethroids, which are altogether more complex and persistent types of chemicals and have a much more devastating effect on beneficial insects and the environment.

Continued →

Pyrethrum plus Alcohol

We've already seen that alcohol boosts the effectiveness of insecticidal soaps; it can also make pyrethrum more effective. Again, it penetrates an insect's waxy protective coating, allowing the pyrethrum to paralyze and kill the pest more quickly. To make this solution, mix 2 parts alcohol with 1 part water, then add the pyrethrum in the concentration called for on the bottle. Do not get this mixture on your skin. If you do, wash immediately with soap and water.

Pyrethrum Blends

In crisis situations, when the life of an important plant is seriously threatened by insect infestation and no other control has worked, you can raise the ante even higher. Potent blends of poisons are available that combine pyrethrum with rotenone, ryania, or both. In a typical blend, the pyrethrum serves as the immediate knockdown agent, while the rotenone or the ryania kills insects over a longer period. Apply these blends at dusk, after honeybees have returned to the hive.

Timed-Release Pyrethrum

For longer term effectiveness, purchase pyrethrum that has been encapsulated so that it functions as a time-released insecticide when sprayed onto plants. It adheres to the leaves of plants and remains potent for up to a week.

Rotenone

Rotenone is refined from the roots of several tropical plants, including derris, cube barbasco, and timbo. Rotenone is a stomach poison. When used properly, it doesn't harm humans, wildlife (except fish), or pets, but it is a very powerful insecticide and should be used with respect. It will kill beneficial insects, including ladybugs and honeybees, as well as pests. You can apply rotenone as a dust; however, less is needed if you dilute it with water and spray it on plants. Use it only at dusk, after the bees have returned to the hive. A 1 percent solution will take care of most insects. If you are dealing with Japanese beetles or weevils, or if the 1 percent solution doesn't seem to be effective, increase the concentration to 5 percent. Rotenone remains potent for two to three days. Spraying once every three days, making two or three applications, should control most troublesome insect pests. Because it is very toxic to fish, do not spray it around bodies of water.

Sabadilla

The seeds of a lily from South America and the Caribbean are the source of sabadilla. One of the safer botanical poisons, it has little effect on mammals, but it's toxic to bees. It is available only as a dust. Wet plants before applying for better coverage. Apply it weekly on the undersides of the leaves of infested plants until the target pests are under control. A contact poison, it controls such pests as aphids, blister beetles, squash bugs, stink bugs, and caterpillars. Sabadilla isn't easy to find, but it is available through mail-order catalogs. One brand name is Red Devil. Unlike most pest controls, sabadilla actually becomes more effective in storage.

INSECT PREDATORS AND PARASITES

As mentioned earlier in this chapter, many species of resident beneficial insects devour thousands of insects each day. Learn to recognize these "good" insects and make them welcome in your landscape.

Because many beneficial insects emerge later in the season than pest insects do, gardeners may be more aware of pest problems early in the season than they are later. When the beneficials arrive, they must have a steady food supply, so resist the temptation to eradicate all insect pests immediately. Beneficial predatory insects will stay in your yard and police it only if there is something for them to eat. Your goal should be to maintain a balance of "good" and "bad" insects, so use pesticides sparingly early in the season before beneficials come on the scene.

Create the Best Environment

While you can buy beneficial insects and introduce them into your garden, it is far cheaper and probably more effective to simply encourage the beneficial species native to your area. Create the kind of environment they like. The more diverse the plantings in and around your yard and garden, the more attractive it will be to a wide variety of helpful insects. The more permanent plantings you have around the yard—perennial beds, woodland gardens, groupings of shrubs—the more stable the habitat you offer for beneficials to reside in year after year. Some homeowners go so far as to set aside a special nursery, or insectary patch, where weeds, brambles, and wildflowers are encouraged to thrive, providing a haven for "good" bugs. (A wildflower meadow would provide the same environment.) These special plantings are most effective within 25 to 50 feet of the plants you are trying to protect, but they provide some protection up to 150 feet away. Hedgerows, windbreaks, and wooded patches also serve as nurseries for beneficials.

As for specific plants, trichogramma wasps find food and winter shelter on buckwheat, dill, mustard, and tansy. Parasitic wasps and flies are especially fond of black-eyed Susans, daisies, goldenrod, and related flowers. General favorites include Queen Anne's lace and other members of the parsley or carrot family (Umbelliferae)—herbs like angelica, anise, caraway, chervil, dill, lovage, and parsley—plus flowers such as asters, bachelor's buttons, milkweed, and yarrow. Some evergreens provide a haven for all sorts of helpful insects. Ample supplies of nectar and pollen provide food for predators when pest populations are low and for many beneficial adult parasites.

Clyde Robin Seed Company offers a wildflower mixture, Border Patrol, which is specially designed to attract and support

beneficial insects. This mix produces an attractive wildflower garden with a secret agenda of supporting a beneficial insect population in your landscape. It contains seeds of angelica, baby-blue-eyes, bishop's flower, black-eyed Susan, candytuft, evening primrose, nasturtium, strawflower, wild buckwheat, and yarrow. Border Patrol is also available through Gardener's Supply.

Entomologist Linda Gilkeson has observed in her research that water is as important to maintaining a beneficial insect population as food and shelter. Consider placing two birdbaths in the yard—one for insect-eating songbirds, the other for beneficial insects. To make a birdbath attractive to insects, stack several piles of small stones in it to allow the insects to drink water without the danger of drowning. Place this bath in among the flowers where birds are less likely to land. You don't want them eating the beneficial insects you are trying to attract. Put the other birdbath out in the open. Birds prefer to land in open areas so they can see cats or dogs approaching. Don't forget a dish of water for your other garden ally, the toad. A sunken dish, perhaps shaded by a low shelter of rocks and/or boards, will keep this companionable, long-lived amphibian eating pests in your garden throughout the season.

BENEFICIAL INSECTS AND NEMATODES AVAILABLE COMMERCIALLY

If you don't want to plant a wildflower patch or set up a birdbath to attract beneficials, you can still purchase beneficial insects and release them in your backyard. While it is not quite as simple as it sounds, this is an effective alternative when time or space limits your ability to attract naturally occurring beneficial insects. It is important to follow directions carefully, lest your newly purchased insects promptly fly away. Make the effort to determine the right time to release these pest fighters and follow the technique correctly so commercial beneficial insects will settle down in your garden.

Timing is critical. Introduce predatory and parasitic insects before pests get out of hand, but not prematurely. There must be sufficient numbers of pests to keep the beneficials busy and well fed. Unless they find insects to eat and the right plants to shelter them, beneficials will go elsewhere. Consider the type of environment needed by the beneficials you plan to purchase. Alter your backyard habitat to make sure that water is available and to provide the types of flowers mentioned above. Following are descriptions of the various predators and parasites that might be able to help you control the insect pests in your flower garden, along with information on how to introduce them into your backyard and keep them there.

Beneficial Nematodes

Not all nematodes are plant parasites. Certain species will help you control pests. These soil-dwelling, microscopic worms burrow inside pest grubs, soil-dwelling caterpillars (like cutworms), and maggots. They release bacteria, which usually kill the host insect within 48 hours. The nematodes then feed and reproduce within the dead insect.

Beneficial nematodes (the best known is *Neoaplectana carpocapsae*) attack black vine weevils, chinch bugs, cutworms, fall armyworms, fire ants, fungus gnats, Japanese beetle grubs, mole crickets, pine weevils, root maggots, rose chafers, sod webworms, strawberry weevils, white grubs, wireworms, and the larvae of cucumber beetles, flea beetles, gypsy moths, and squash vine borers. They will not harm beneficial insects or earthworms.

Beneficial nematodes are sold in packages of 1,000,000 and up. (Ten million—the amount in a box of BioSafe, one trade name for the nematodes—will treat up to 225 square feet.) They look like powder and can be stored in your refrigerator from two to six months. Mix them with water and use a sprayer or watering can to introduce them into the soil. Apply as soon as plants are up. An application of 50,000 nematodes per plant, for example, will control iris borers. To treat container-grown plants, apply roughly 5,000 nematodes to each gallon of soil. Water the nematodes into the soil around the base of your plants in the early spring. You should see effects within five days, but allow two months for maximum control.

Nematodes will overwinter in the soil as far north as Minnesota, but their survival rate is not high enough to provide effective insect control the following season, so reapply each year. Only the infective juvenile stage of the nematode is functional as an insect control.

Green Lacewing Larvae

Of all the beneficial insects you can buy through the mail, green lacewings (*Chrysopa* spp.) are probably the most effective all-purpose controls. Various species occur naturally throughout North America, but all have a slender body and long, delicate, transparent green wings. They are ½ to ¾ inch long and lay their tiny white eggs on threadlike stalks on the undersides of leaves. The adults eat pollen, nectar, and honeydew. It's the larvae, known for their voraciousness as aphid lions, that feed on pest insects. They are alligator-shaped, yellowish gray with brown marks and tufts of long hair, and they grow to about ⅜ inch long. Their most distinctive feature is a pair of long, thin jaws, which curve together like ice tongs. Three or four generations are produced each year. Lacewings pass the winter in the pupal stage in cocoons.

The insects lacewing larvae attack include aphids, leafhopper nymphs, mealybugs, mites, scale, whiteflies, and the eggs of caterpillars, mites, thrips, and other small pests. Ravenous little creatures, they can eat up to 60 aphids an hour. By boosting the natural lacewing population in your flower beds in the early summer, you can get a jump on these insect pests. Lacewings cannot bear the cold, so wait until the average air temperature is at least 70°F.

Continued ➔

You can purchase lacewings in egg or larval form, although eggs are trickier to handle. Approximately 5,000 lacewing larvae will cover an area of about 2,500 square feet. They like to eat each other, so release them as soon as you receive them by placing them in different areas of the yard. Unlike other beneficial predators, lacewing larvae tend to stay in the area where they're released. But because their effective period is short—they become adults in one to three weeks—your best bet for control is to make three releases, one every five to seven days.

If you've ordered eggs, don't be surprised to find some larvae in the container; the eggs may have hatched in shipment. The eggs must be lodged gently in leaf and stem crevices, in spaces between petals, or in flower centers.

To encourage continued residence of newly introduced lacewings, place Wheast around the yard and garden. This is a sweetened dairy product sold as food for beneficial insects. Lacewing adults will also eat a honeydew-like mixture made from 1 part sugar and 1 part brewer's yeast in water and such commercially available versions as Bug Chow and BugPro, which should be mixed with enough water to give a molasses-like consistency. Put drops of this mixture on plants that are vulnerable to the pests you want lacewings to control. And don't forget to include nectar-rich flowers like oleander, Queen Anne's lace, and yarrow in your flower beds—adult lacewings will feel right at home.

Ladybugs

Ladybugs (*Hippodamia convergens*) are the beneficial insects that first come to mind for most of us. We learned in childhood that these rather endearing little orange-colored beetles with black spots are welcome in the garden. The reason is that both the larvae and the adults eat small insects. They can eat up to 40 aphids an hour—one adult may consume 5,000 aphids—and will also make meals of chinch bugs, mealybugs, scale, spider mites, thrips, whiteflies, and other soft-bodied pests, as well as various small larvae and insect eggs.

Ladybugs reverse their coloring from larval to adult stage. The ¼-inch-long beetles are orange to red with black spots, and the larvae are black with orange spots. The larvae are about ½ inch long and are usually covered with spines. The cylindrical eggs are yellow-orange. There is only one generation each year. In the East and Midwest, ladybugs overwinter in weedy areas or garden trash; in the West, they migrate to the mountains each fall.

Estimates differ, but plan on releasing about one ladybug per square foot—2 to 3 gallons of them per acre. Released too early in the season when their food supply is low, ladybugs will be forced to seek food in other yards. If you're not sure whether the pest population in your yard will support all the ladybugs you've bought, release only some of them and store the rest in the refrigerator, where they'll survive for up to three weeks.

Beneficial Insects and the Plants That Attract Them

To attract beneficial insects to your garden and encourage them to stay, grow the plants they prefer.

Lacewings. Members of the carrot family, oleander, and wild lettuce.

Ladybugs. Alfalfa, angelica, coffeeberry, evergreen euonymus, goldenrod, Mexican tea, morning-glory, oleander, and yarrow. Ladybugs also like ragweed, but you probably don't want to plant this hayfever source in your garden!

Parasitic wasps. Members of the carrot family, members of the daisy family, buckwheat, buttercup, goldenrod, oleander, strawberries, and white clover.

Syrphid flies and hover flies. Members of the daisy family.

Release them late in the evening when the air has cooled off and dew has settled on the grass. If the ground is dry, lightly water the yard and garden. When releasing ladybugs, gently place handfuls of beetles at the base of your pest-ridden plants. Cover them immediately with damp straw or hay. They will soon climb the plant and begin to hunt for food. Walk 20 to 30 paces and release another handful near another group of infested plants. Handle ladybugs gently so as not to excite them into flight. Under normal conditions, they will mate within 48 hours and produce aphid-eating offspring in two weeks.

To encourage ladybugs to stay in your yard, grow pollen- and nectar-producing plants such as alfalfa, angelica, coffeeberry, evergreen euonymus, goldenrod, Mexican tea, morning-glory, oleander, and yarrow. Commercially available food attractants such as Bug Chow and BugPro, which should be mixed with water until molasses-like, then placed in droplets on the plants, also help newly released adults settle down.

Parasitic Wasps

These tiny insects, though a danger to insect pests, do not sting gardeners. They willingly attack a variety of aphids and caterpillars. A few different types are available commercially through mail-order catalogs.

The adults of each of these parasites feed on nectar, which they obtain from weeds and wildflowers, particularly those in the daisy and carrot families. By planting some of these in your yard, you will encourage beneficial wasps to stay. Perhaps the best plant for all wasps is fennel. It seems to attract a large number of beneficial insects all season long.

Braconid Wasps

These wasps lay their eggs in the bodies of aphids, cucumber beetle grubs, cutworms, gypsy moths, hornworms, tent caterpillars, and various other larvae. The larvae hatch and grow inside their hosts, weakening and often killing them. Then they pupate on the backs of the hosts. These pupae are the "wasp eggs" so often seen on the backs of parasitized tomato hornworms.

Braconid wasps are sold commercially as eggs. The adults, which can be black, red, or yellow, are just 1/16 to 5/8 inch long. They prefer warm, humid, conditions with temperatures above 59°F.

Chalcid Wasps

Chalcid wasps seek out aphids, asparagus beetles, leafhoppers, scale, whiteflies, and various caterpillars and other beetles. They lay their eggs in or on the pest. The larvae grow inside the pest, weakening and eventually killing it. Some adults also feed directly on the host. The adult chalcid is just 1/16 to 3/8 inch long, so you'll probably not see them unless you take pains to do so. Chalcid wasps are found throughout North America. Like the braconid wasps, chalcids prefer warm, humid conditions. One chalcid wasp of interest to flower gardeners, the trichogramma wasp (see below), is available commercially.

Ichneumon Wasps

Species of ichneumon wasp range in size from 1/8 to 3 inches long and in color from yellow to brown and black. Adults lay eggs in borers, cutworms, eastern tent caterpillars, fall webworms, sawflies, and other larvae. Ichneumon wasps are not commercially available, but are found naturally throughout North America.

Trichogramma Wasps

The tiny (1/45-inch-long) trichogramma wasps kill the eggs of insect pests. The female wasp lays her eggs in the pest egg, and when the trichogramma egg hatches into a larva, it consumes its host. Among the 200 species of pest that trichogramma wasps parasitize are aphids, armyworms, cabbageworms, cutworms, fall webworms, gypsy moths, hornworms, leafrollers, loopers, mealybugs, scale, whiteflies, and various beetle larvae.

The release of trichogramma wasps is more effective when coupled with a spray of Bt (*Bacillus thuringiensis*) on infested plant leaves (see page 840); a sequence of three smaller releases is more effective than one large release. Make the three releases at two-week intervals so the wasps can parasitize host eggs as they're laid. The most effective species for protection of ornamentals is *Trichogramma minutum*, while the best species for general garden use is *T. pretiosum*. Trichogrammas are widely available commercially. Shipped in the egg, 20,000 will control host species on ½ acre.

Beneficial Insects Available Commercially

- Beneficial nematodes
- Green lacewing larvae
- Ladybugs
- Parasitic wasps
  - Braconid wasps
  - Chalcid wasps
  - Ichneumon wasps
  - Trichogramma wasps
- Praying mantids
- Predatory mites

Praying Mantids

These fearsome-looking creatures, the Darth Vaders of the insect world, are known for their voracious appetites for insects, including flies, mosquitoes, and moths. Various species are found throughout North America. They may be green or brownish and are about 2 inches long. They have papery wings and enlarged front legs adapted for grasping. Mantids overwinter in the egg stage. They deposit their eggs on twigs and grass stems in an egg case that looks like it was made from papier-mâché. Each case contains 200 or more eggs. One generation of mantids occurs each year.

When you buy praying mantis egg cases, you may get more than you bargained for. Unlike most of the other beneficials, the mantids prey on all insects, including each other. Each egg case may produce a couple of hundred hungry little mantids, but they will probably eat each other before they start working on your pest problem. The few that do survive will establish territories and drive off others of their kind. Regardless of how many egg cases you set out, by midsummer there will be only two or three mantids in a 20-by-40-foot flower garden. At this rate, those mantids will have cost you a couple of dollars each, and it is likely that you already have some in your backyard anyway.

If this hasn't discouraged you, and you still want to purchase mantids, try about three egg cases for 5,000 square feet of garden. To increase the young mantids' survival rate, put the egg cases in a screen-covered box. Check them every day after the trees begin to leaf out. Provide them with water, and, after two days, separate the newborns before they start eyeing one another. Scatter them around the garden. They will still drive off many of their brothers and sisters, but coverage should be fairly good, and you may even have a generation that will reproduce and help provide control next year.

Continued ➔

Predatory Mites

Predatory mites will attack other mites, including spider mites and greenhouse mites. One release per season should provide continued control, since some mites will remain in the garden after the pest outbreak is stopped. You'll only need two predatory mites for each square foot or plant less than 2 feet tall; for larger plants, release two per large stem or branch. Mites flourish in warm weather with temperatures averaging between 68° and 86°F. If daytime temperatures are too low, their reproductive rate slows.

ANIMAL PREDATORS

In addition to naturally occurring spiders and beneficial insects like assassin bugs, ground beetles, robber flies, rove beetles, soldier beetles, and others that will police your yard for pests, you can count on help from larger beneficial creatures. Among these allies are bats, toads, songbirds, and lizards, all of which will eagerly gobble up grubs or binge on beetles. Of course, some of these animals can make pests of themselves, as well. For instance, skunks are voracious eaters of grubs and larvae, but they may inadvertently tear up your seedlings while looking for them. A few seasons of experience will indicate which ones are most valuable for your pest control problems and which ones need to be denied entry.

This inventory of pest-eating insects and animals that reside in a balanced, active backyard ecosystem provides a persuasive argument against the use of garden chemicals that might harm these friends of the garden. If you attract and encourage beneficial insects and predatory animals, you will find that most of your insect problems will be reduced considerably. The process may take a few years, but the results will be worth the effort. Once you have achieved a flower garden where a variety of plants, insects, and animals are in balance, no pest problem should get out of control. Remember, too, that when you have a system in which all the elements are balancing and controlling each other, you'll have less work to do.

Bats

Bats suffer from bad press. Stories of vampires, bites in the neck, and, lately, rabies obscure the ways in which bats offer very real benefits to the gardener. These unobtrusive mammals do not bother humans unless they are cornered or provoked. They venture out in the early evenings to make a meal of insects. A single bat can eat over 1,000 mosquitoes a night. And they produce bat guano, an excellent source of organic nitrogen. So, if you have a multitude of night-flying pests, you'd be better off putting up bat houses (now readily available from suppliers that offer a wide selection of birdhouses and feeders) than putting out the garlic.

Birds

Songbirds are seldom credited for all their help in controlling flower garden pests. Although many adult songbirds eat seeds, they also harvest tens of thousands of insects during the weeks when they raise their young. Baby birds cannot digest seeds and must be fed fresh insects. Increase your yard's bird population and you'll reduce the pest population.

Feeding birds during the winter months contributes significantly to maintaining a good-size bird population in your area. To encourage them to stay around over the summer, continue supplemental feeding at the feeder. Put out less food, less often. This will encourage them to stay in your yard without making them entirely dependent on the feeder.

Provide an inviting backyard habitat for birds. Landscape with plants that offer tasty seeds and berries. *Echinacea* and *Rudbeckia* are favorite seed producers, and roses that produce large hips are good for winter nourishment. In addition, provide trees and shrubs where birds can take shelter and hide from the neighborhood cats and dogs. A supply of water year-round is a necessity: Sometimes water is more important than food. Remember to put the birdbath or water dish in the open where birds can see cats and dogs coming. Consider providing birdhouses and nesting platforms; then you'll be sure to have many parent birds collecting insects for their young.

Some of the best pest patrollers are house wrens, northern (formerly Baltimore) orioles, and chickadees, but many other birds will help you control insect pests. Even the lowly starling and the pugnacious English sparrow devour literally thousands of pest insects or insect larvae each season.

Frogs and Toads

Frogs and toads are princes when it comes to pest control. In a toad's eight-month active season, it can eat 24,000 insects—think of its 30-year lifetime average! Unfortunately, they don't discriminate between pests and beneficial insects. They'll happily gobble up large numbers of cutworms or potato beetles, but they're just as likely to eat helpful spiders or ladybugs. Frogs are particularly fond of sow bugs, and toads will devour ants, aphids, caterpillars, cutworms, grasshoppers, slugs, spiders, and squash bugs, but in general, what they eat depends on what happens to be in your yard. Unless you have a pond or water garden, you shouldn't attempt to keep frogs, but a half-buried water dish and a few hiding places will spell home to a toad. You can encourage toads to stay by leaving the door or driveway light on at night—they'll relish all those moths and beetles on the screen door.

Lizards

If you live in the southern or western states, the lizards you see lolling about on some sunny rock or warm patch of ground will help keep the insect population down. Lizards prefer stony, open terrain. Vertical surfaces like trees, stone walls, fences, and walls of abandoned buildings are favorite haunts, though anoles (our American chameleons) seem to like hedges, and beautiful, blue-lined skinks enjoy sunning on patios and

chimneys. Lizards are harmless, amusing reptiles that can provide hours of leisurely observation as you go about your garden chores or indulge in a bit of sunning yourself. They should be encouraged to call your yard their home.

Skunks

Skunks eat a wide variety of food, including chicken eggs, mice, snakes, and yellow jackets, but their favorite fare are plant-eating insects and larvae lurking in flower beds and lawns. They are particularly good at rooting out grubs and cutworms. Of course, they also love fruit, but they usually gather pieces that have fallen to the ground. So, if you see a skunk waddling across the lawn, don't chase it, especially since it will probably spray you with a fragrance you won't enjoy wearing.

Snakes

While certain parts of the country are plagued by genuinely dangerous snake species, most snakes that find their way into your backyard only represent a threat to garden pests. Garter snakes and the like prey on rodents and snap up bugs and beetles. Try to overcome any antipathy you may harbor toward these creatures and permit them to hunt in and around your flower beds. They will return the courtesy by consuming pest insects for you and curbing the population explosion of bulb-eating voles and mice.

Preventing Pest Damage

Of course, keeping insect pests away from your plants means even less work for you. You can discourage pests by following good gardening practices. Take a few precautionary steps before and after the growing season to foster plant vigor, because healthy plants are less susceptible to attack. Just a little more effort up front will save hours of labor later on.

YARD AND GARDEN CLEANUP

Perhaps the most important step you can take to maintain a pest-free and disease-free garden is to keep the yard and garden neat and clean. Fallen, decaying leaves and twigs shelter slugs, snails, and other pests that hide out during the day. Rotting weeds and plants, as well as soggy leaves and twigs, harbor pest insects and disease spores over the winter. Keeping your yard free of clutter and plant debris is essential to keeping down populations of insect pests next season.

Fall Cleanup

Clean up thoroughly in the fall. When all leaves and twigs have dropped from the shrubs and trees, and annuals and perennials have faded and died, collect all this organic material and compost it. However, refuse from diseased plants, as well as organic mulch that has been used during the growing season and may harbor disease, should be trashed. Get down to bare soil in all your gardens where annuals have been, around perennials, and under all shrubs.

Once your garden soil is cleared, cultivate it by raking thoroughly, if possible. In perennial beds and under shrubs, cultivate only 1 or 2 inches to avoid damaging the shallow root systems. This fall cultivation buries those insects that normally overwinter on the surface of the soil and brings to the surface those that prefer to snuggle a little deeper in the earth. The former suffocate; the latter will be eaten by birds.

This is also a good time to improve soil texture by incorporating humus-rich materials like shredded leaves and compost, and to add amendments like lime, greensand, or fresh manure that need a season to break down. By spring, the nutrients will be available to your plants.

About two to three weeks after that first deep cultivation, shallowly rake cleared gardens and bare areas again. This exposes more larvae to birds and other predators. Then leave the soil bare until it freezes hard.

Once the soil has frozen hard, lay a 2- to 6-inch layer of organic mulch over all the bare soil in the garden and around the shrubs. In those areas of the South where there is no freeze, leave the soil bare for at least a month before mulching it. Leaves chopped in a shredder, or shredded by running the lawn mower back and forth over them, are ideal mulching material. In the fall, leaves are plentiful and make excellent composting material next spring when they are removed before planting.

Spring Cleanup

After a major fall cleanup, spring preparation is simple. Remove the winter mulch from any areas where spring bulbs and early-blooming perennials have been planted. Leave the mulch around the shrubs and supplement it later in the season.

BARRIERS

Barriers are effective in preventing pest infestations in flower beds. There are a variety of barriers that will discourage pests from attacking ornamental plants by denying them access throughout the season.

Mulch

Among its other benefits, mulch can block some insect pests from reaching your plants, especially those that overwinter just under the surface of the soil. At the very least, it controls weeds, which may harbor pests. Black plastic mulch or any of the new agricultural fabric (geotextile) mulches laid on bare soil will prevent many larvae from emerging. Agricultural or landscape fabric mulch effectively prevents soil-dwelling insects like weevils from climbing up from the soil and attacking the foliage of flowering plants. Cut a circle of material wide enough so that it extends half again wider than the width of the plant all the way around. Fit the fabric mulch snugly around the stem of the plant and fasten it firmly to the soil. This makes a barrier, preventing the weevils from emerging from the soil.

Continued ➔

Flexible Copper Sheeting

If your flowers are regularly raided by slugs and snails, bar their path with Snail-Barr, a 3-inch-wide band of thin, flexible copper sheeting. You can wrap it around the outside edge of a window box or planter, or around the lip of a barrel or flower pot. If you grow flowers in raised beds that are edged with boards or railroad ties, attach Snail-Barr around the outside. Slugs and snails get an electric shock when their slimy bodies encounter the copper, and they don't stay around to prolong the encounter.

Diatomaceous Earth

The needle-sharp crystals of diatomaceous earth act as an effective barrier to soft-bodied insects, like slugs and snails.

RESISTANT PLANT VARIETIES

One of the best ways to prevent pest problems is to grow plants that simply aren't bothered by insects. Over the years, researchers have developed flower cultivars that are resistant to specific insect pests. There aren't yet as many insect-resistant ornamentals as there are vegetables, but researchers are breeding new insect- and disease-resistant flowers every season. Keep your eye on the market for new developments, and check seed catalogs for the resistant cultivars that will grow best in your area.

LEARN INSECT EMERGENCE TIMES

Learn when a specific pest insect is likely to appear in your garden. Timing is crucial. If you are prepared at the right time with the right control, you can stop a problem before it has begun. Each species of insect has its own fairly predictable pattern of birth, feeding, maturity, reproduction, wintering, and death. If you can learn these patterns and how they coincide with your yard and garden calendar, you'll be able to predict when problems might arise. To facilitate preventive measures, it's especially important to know when overwintering pests are due to emerge in your flower garden.

The emergence times of insects vary from region to region, even neighborhood to neighborhood. Air temperature, moisture, and the availability of food all affect an insect's schedule. Check with your cooperative extension agent for a rough idea of when the problem insect typically appears, then record these times. More important, observe your garden and mark down the date when you begin to see each pest arrive. To make these emergence times easier to remember, connect them with some other garden-related event, such as the budding or blooming of lilacs in the spring, or jot them down in a garden diary.

Bad Bugs

Distinguishing bad bugs from the good guys can be difficult, especially since bad bugs don't carry tiny flags with the word "pest" written on them. But while lots of insects may reside in your garden, most of them aren't harmful. That's why you should use the following guide to help you identify a suspected pest before you decide to do it in.

Light Snacking Is OK

Even when you find pests in your garden, keep in mind that most of their snacking doesn't particularly endanger your vegetables, flowers, or landscape plantings. As we mentioned earlier, your plants can tolerate some damage. For example, holes in the leaves of a potato plant or an apple tree only affect the crop's yield if quite a bit of damage is done. For this type of pest, you might not need to do anything, or you may need to do something only in years with particularly heavy outbreaks. Many insect populations rise and fall over a period of years, so outbreaks over a few years may be followed by several years without damage.

PLANNING AHEAD

Although you'll find descriptions of more than 20 pests in the following list, don't be intimidated! They won't all reside in your garden. Only a few are a problem for any given plant or region of the country. Once you find out which pests are regular problems where you live, the best thing you can do is to plan ahead to prevent the problems next year. Preventing pest damage is easier and more effective than treating your plants or trying to control the pests after the damage occurs.

Aphids

Aphids are soft, pear-shaped, and very tiny (1/16 to 3/8 inch long). Two short tubes project backward from the tip of their abdomen. Aphids have long antennae. Some types of aphids have wings, which are transparent, longer than their body, and held like a roof over their back. Aphids may be green, pink, yellowish, black, or powdery gray. Nymphs resemble adults but are smaller and wingless.

WHERE THEY LIVE

You'll find aphids throughout North America.

THEIR LIFE CYCLE

Aphids reproduce like there's no tomorrow. Female aphids can reproduce without mating, giving birth continuously to live nymphs. Nymphs mature in 1 to 2 weeks and start producing offspring themselves.

When days become shorter in the fall, both males and females are born. They mate, and then females lay eggs on stems or in bark crevices. The eggs overwinter and hatch the following spring. In very mild climates and in greenhouses, aphids may reproduce year-round.

PLANTS THEY ATTACK

Aphids feed on most fruit and vegetable plants, flowers, ornamentals, and shade trees.

WHY THEY'RE A PROBLEM

Both adults and nymphs suck plant sap, which usually causes distorted leaves, buds, branch tips, and flowers. Severely infested leaves and flowers may drop. As they feed, aphids excrete a sweet, sticky honeydew onto the leaves below. This allows a sooty mold to grow, which, in addition to being ugly to look at, blocks light from leaves. Also, some aphids spread viruses as they feed.

ORGANIC DAMAGE CONTROL

- Drench plants with strong sprays of water from a garden hose to kill aphids. (A hard, driving rainstorm will have the same effect.)
- Keep your plants as healthy as possible, and spray dormant oil to control overwintering eggs on fruit trees.
- Attract predators by planting pollen and nectar plants such as yarrow and sweet alyssum.
- Control ants that guard aphid colonies in trees from predators by placing sticky bands around the trunks.
- Spray aphids with insecticidal soap, summer oil (on tolerant plants), and homemade garlic sprays.

Black Vine Weevils

Adult weevils are oval, brownish gray or black, and ⅓ inch long. They have a pattern of small yellow patches on their backs. Their larvae are fat, white grubs that are up to ½ inch long with yellowish brown heads.

WHERE THEY LIVE

You'll find black vine weevils in the northeastern United States, as well as from California to the Pacific Northwest.

THEIR LIFE CYCLE

For weevils, reproducing is solely women's work, as there are only female weevils—no males. The adults emerge from the soil in June and feed for several weeks before laying eggs in the soil around host plants.

The eggs hatch in about 10 days and the larvae immediately burrow into the roots to feed for the rest of the season. They stay in the soil over the winter, then resume feeding on roots the following spring. The larvae pupate in early spring, completing the cycle.

PLANTS THEY ATTACK

Black vine weevils most commonly attack blackberry, blueberry, cranberry, and strawberry plants, as well as some ornamentals, particularly azaleas, camellias, rhododendrons, wisterias, and yews.

WHY THEY'RE A PROBLEM

Weevils chew along leaf edges, leaving small, scalloped bite marks. Adults rarely cause serious damage, but larvae can be very damaging because they feed on plant roots. Their feeding stunts plant growth and may indirectly kill plants by allowing disease organisms to enter injured roots.

ORGANIC DAMAGE CONTROL

- At night, when they feed, knock weevils off plants onto a sheet on the ground and destroy them. (If you don't want to squish them, you can just drop them in a bucket of soapy water and drown them.)
- Lay boards under plants and check for weevils hiding under them during the day.
- Plant resistant rhododendron and azalea varieties that have rolled leaf edges, which prevent weevils from grasping an edge to feed.
- Intercept weevils as they climb shrubs by tying a 6-inch-high band of plastic wrap painted with sticky trap glue around the trunk.
- Add bird-friendly shrubs, birdbaths, and feeders to your landscape—birds and other predators find black vine weevils delicious.

Cabbage Loopers

Cabbage looper adults are mottled gray-brown moths with a silvery, V-shaped spot in the middle of each forewing. Their wingspan is 1½ inches. Because they fly late in the evening, you rarely see them. Their larvae are green caterpillars with pairs of wavy, white or light yellow lines down their backs and one line along each side.

WHERE THEY LIVE

Cabbage loopers are found throughout North America.

THEIR LIFE CYCLE

Adult moths emerge in May from their overwintering cocoons to lay eggs. The eggs hatch in 3 or 4 days and the larvae feed for 2 to 3 weeks. They pupate for up to 2 weeks in thin silk cocoons attached to the stems or undersides of leaves. Three or four generations of cabbage loopers may appear in a year, depending on where you live.

PLANTS THEY ATTACK

As you might expect, cabbage loopers attack mainly cabbage and cabbage-family plants. They'll also feed on beets, celery, lettuce, peas, spinach, tomatoes, and flowers, including carnations and nasturtiums.

WHY THEY'RE A PROBLEM

Cabbage looper caterpillars damage plants by chewing large holes in leaves. If you have lots of them, they can ruin whole plants. Larvae are most damaging during the last few days of their development.

Continued →

ORGANIC DAMAGE CONTROL

- Handpick caterpillars several times a week and spray *Bacillus thuringiensis* var. *kurstaki* (BTK) as well.
- Attract predatory and parasitic insects to the garden with pollen and nectar plants.
- If you live in the North, start your cabbage indoors and put the plants out in the garden very early to avoid peak populations.
- At the end of the season, bury spent cabbage plants to destroy cocoons before adults emerge in spring.
- Many native parasites and predators attack cabbage loopers. Invite these helpers into your garden by planting flowers for them to feed on when loopers are not prevalent. Beneficial insects prefer tiny flowers like those that make up the large, flat umbels of parsley, dill, fennel, and coriander. Alyssum and tansy are also known to attract beneficials.

Cabbage Maggots

Adult cabbage maggots are nondescript gray flies, ¼ inch long, with long legs. The white, tapering larvae (which you will probably see much more often than the adult flies) burrow into the roots of plants, where they cause serious damage.

WHERE THEY LIVE

Cabbage maggots are found throughout North America.

THEIR LIFE CYCLE

In warmer regions, adult flies begin emerging in late March. The females lay eggs in the soil beside the plant roots. After they hatch, the larvae feed on the fine roots, then tunnel into the taproots, feeding for 3 to 4 weeks. They pupate, and adults emerge in 2 to 3 weeks. In most areas, cabbage maggots produce two to four generations a year. The fall generation of pupae overwinters several inches deep in the soil.

PLANTS THEY ATTACK

Cabbage maggots attack all cabbage-family plants.

WHY THEY'RE A PROBLEM

In the early stages of infestation, plants wilt in the midday heat. Young plants often die, either directly from maggot feeding or because the injured roots become diseased and rot. Older plants may survive but may produce only a small crop. Cabbage-family root crops, such as turnips and radishes, may be ruined. Maggots do the most damage early in the season when the weather is cool and moist. In hot, dry summers, most eggs from later generations never hatch.

ORGANIC DAMAGE CONTROL

- Avoid the most damaging early generation of flies by planting radishes very early.
- Cover seedlings and small plants, such as radishes and Chinese cabbage, with floating row covers, burying the edges under soil well.
- Set out transplants through slits in 6-inch squares of tar paper to prevent flies from laying eggs near stems, or wrap stems with paper 1 to 2 inches above and below the soil line before planting.
- Burn or destroy roots of cabbage-family plants as soon as you harvest the crop.
- Try repelling egg-laying flies by mounding wood ashes, hot pepper, or ginger powder around your plant stems.

Colorado Potato Beetles

Adults are yellowish orange, with 10 lengthwise black stripes on their wing covers and black spots on their middle section. They are ⅓ inch long. The larvae are dark orange, humpbacked grubs, ranging from 1/16 to ½ inch long. They have a row of black spots along each side. The beetles lay bright yellow eggs on end in upright clusters on the undersides of leaves.

WHERE THEY LIVE

Colorado potato beetles are found throughout most of North America.

THEIR LIFE CYCLE

In spring, the beetles emerge from the soil to feed on potato plants as soon as the first shoots are up. After mating, the females lay up to 1,000 eggs each during their several-month life span. The eggs hatch in 4 to 9 days, and the larvae feed for 2 to 3 weeks. They bury into the soil to pupate for another 2 to 3 weeks, and adults emerge in 5 to 10 days. These beetles may produce up to three generations a year. Adults and sometimes pupae overwinter several inches deep in the soil.

PLANTS THEY ATTACK

Colorado potato beetles are major pests of potatoes and, in some areas, damage tomatoes and eggplants, too. They may also attack related plants, such as petunias.

WHY THEY'RE A PROBLEM

Both adults and larvae chew on leaves and stems of potatoes and related plants. Young plants may die, while older plants can be severely defoliated, which can leave you without any spuds. A moderate amount of feeding, though, doesn't harm plants or reduce yields.

ORGANIC DAMAGE CONTROL

- Choose plant varieties that have some resistance to potato beetles.
- Mulch plants deeply with straw, and trap overwintered beetles in plastic-lined trenches around the potato patch.

(The beetles have an easy time crawling or falling into the trench, but they just slip on the plastic when they attempt to crawl back out.)

- Cover susceptible plants with floating row covers until midseason.
- To control larvae, spray *Bacillus thuringiensis* var. *san diego* (BTSD) as soon as eggs are present.
- In the fall, till the soil to kill overwintering beetles.

Corn Earworm/Tomato Fruitworm

Adults are large, yellowish tan moths with a wingspan of 1½ to 2 inches. The larvae are light yellow, green, pink, or brown caterpillars, 1 to 2 inches long, with white and dark stripes along their sides. Eggs are round and light green, with a ribbed pattern, and are laid singly on undersides of leaves or on corn silks.

WHERE THEY LIVE

This pest is found throughout North America.

THEIR LIFE CYCLE

Adult moths emerge in early spring in the south to lay eggs, which hatch in 2 to 10 days. Some moths migrate northward, flying long distances before laying eggs later in the season. Caterpillars feed for 2 to 4 weeks, then pupate in the soil. New moths emerge 10 to 25 days later. Pupae overwinter in the soil, although earworm pupae aren't hardy enough to survive the winter in the northern United States and Canada. Corn earworms produce up to four generations a year.

PLANTS THEY ATTACK

Corn, peppers, and tomatoes are the main plants that earworms/fruitworms attack, but the pests have also been reported on beans, cabbage, okra, peanuts, squash, and sunflowers.

WHY THEY'RE A PROBLEM

The caterpillars feed on fresh corn silks, entering the ear from the tip, then moving down the ear, eating kernels as they go. In tomatoes (which is why they're also called tomato fruitworms), the caterpillars eat the flower buds, chew large holes in leaves, and burrow into ripe fruit. They also chew leaves of other plants.

ORGANIC DAMAGE CONTROL

- Plant corn varieties with tight husks to prevent larvae from entering.
- Attract native parasitic wasps, lacewings, and minute pirate bugs by interplanting with pollen and nectar plants.
- Avoid attracting moths to your garden by keeping nearby lights off at night.
- Inspect plants frequently and handpick caterpillars.
- Apply several drops of vegetable oil to the tip of each ear of corn 3 to 7 days after the silks first appear.

Cucumber Beetles

Spotted cucumber beetle adults are greenish yellow, about ¼ inch long, with 12 black spots on their wing covers. The larvae are ¾ inch long, slender, and white with reddish brown heads. **Striped** cucumber beetle adults are yellow, ¼ inch long, with black heads and three wide black stripes on their wing covers. Their larvae look the same as **spotted** cucumber beetle larvae.

WHERE THEY LIVE

Both types of cucumber beetles are found throughout most of North America.

THEIR LIFE CYCLE

Spotted cucumber beetles spend the winter under crop debris and clumps of grass, emerging in spring to lay eggs in the soil close to plants (particularly corn). When the eggs hatch, larvae feed in roots of plants for 2 to 4 weeks, then pupate, producing up to three generations a year. (These larvae are a real problem in southern regions, where they're known as corn rootworms.) **Striped** cucumber beetles overwinter in dense grass, emerging from April to early June. Striped cucumber beetles feed on weed pollen for 2 weeks, then lay their eggs. After the eggs hatch, the larvae burrow down to feed on roots for 2 to 6 weeks, after which they pupate. They produce up to four generations a year.

PLANTS THEY ATTACK

These pests eat corn, cucumbers, melons, pumpkins, and squash.

WHY THEY'RE A PROBLEM

Larvae tunnel into the base of stems and feed on roots, often killing young plants. Adult beetles eat holes in leaves and chew on fruit skin. Cucumber beetles are also thought to transmit bacterial wilt and mosaic viruses, which can cause more damage than the beetles' direct munching.

ORGANIC DAMAGE CONTROL

- Plant wilt- and mosaic-resistant cucumber, squash, and melon varieties to avoid the main damage from these beetles.
- As soon as the seedlings emerge, cover your plants with floating row covers and secure the sides by covering them with soil. When the plants begin to flower, lift the covers for a few hours each morning so bees can pollinate the plants.
- After harvest, pull out and destroy infested spent plants to eliminate overwintering sites.

Continued ➔

Cutworms

Adult cutworms are large, brownish or gray moths with 1½-inch wingspans. The larvae (which do the damage) are fat, greasy gray or dull brown caterpillars with shiny heads.

WHERE THEY LIVE

You can find cutworms throughout North America.

THEIR LIFE CYCLE

Adult moths emerge from the overwintering pupae and lay their eggs on grass stems or in the soil from early May to early June. After the eggs hatch (in 5 to 7 days), the cutworms feed on grass and other plants for 3 to 5 weeks, then pupate into the soil. Moths emerge from late August to early September, producing the second generation of the year.

PLANTS THEY ATTACK

These pests attack most early vegetable and flower seedlings, shoots, and transplants.

WHY THEY'RE A PROBLEM

Cutworm caterpillars feed at night on young plants, usually cutting the stem at or just below the soil line so that the plant topples over. They may completely eat seedlings.

ORGANIC DAMAGE CONTROL

- Protect transplants by putting collars around the stems. You can cut empty paper-towel or toilet-paper rolls into sections to make collars, or use small empty tin cans with the ends removed. Press the collars about 1 inch into the soil.
- Dig around the base of damaged transplants in the morning and destroy hiding larvae.
- Avoid the main population of cutworms by planting later in the season.

European Corn Borers

Adult females are pale, yellowish brown moths with 1-inch wingspans. They have dark, zigzag patterns across the wings, male moths are smaller and darker. Larvae are gray or beige, about 1 inch long, with brown heads. They have small brown dots on each segment. Corn borer eggs are white to tan. You'll find them on undersides of leaves in masses of 15 to 20 overlapping eggs.

WHERE THEY LIVE

You'll find European corn borers throughout the Midwest to eastern North America.

THEIR LIFE CYCLE

Moths generally emerge from dead cornstalks and plant stems (left from last year's garden) in June. They lay eggs from late June to mid-July. The eggs hatch in a week and the larvae feed for 3 to 4 weeks before spinning a delicate cocoon inside a stalk. The protected cocoons can survive over winter. There are several different strains of corn borers, and they differ in the number of generations a year (from one to three).

PLANTS THEY ATTACK

Corn is the major victim of the borers, and in some regions it is the only vegetable they attack. In other areas, borers may also damage beans, peppers, potatoes, and tomatoes.

WHY THEY'RE A PROBLEM

Young caterpillars feed on the first whorls of corn leaves, on corn tassels, and beneath the husks of ears. Older larvae burrow into cornstalks and also feed in tassels and ears. Boring weakens stalks, causing them to break easily.

ORGANIC DAMAGE CONTROL

- Start by planting corn varieties with strong stalks and tight husks.
- If you have lots of European corn borers, remove the tassels from two-thirds of your corn plants before the pollen sheds. This eliminates many larvae in the tassels, while leaving enough tassels for pollination.
- Spray *Bacillus thuringiensis* var. *kurstaki* (BTK) twice, a week apart, on leaf undersides and into the tips of corn ears.
- European corn borers overwinter in cornstalks and plant debris, so clean up your corn patch in the fall. Shred and compost the stalks or dispose of them immediately after harvest.

Flea Beetles

Adult flea beetles are very tiny—just 1/10 inch long. They're black, brown, or bronze with enlarged hind legs. They jump like fleas when they're disturbed. The larvae live in the soil and are thin, white, legless grubs with brown heads.

WHERE THEY LIVE

Flea beetles are found throughout North America.

THEIR LIFE CYCLE

Adults emerge from the soil in spring to feed and lay eggs on the roots of plants. They die out by early July. The eggs hatch in about a week, and the larvae feed for 2 to 3 weeks. They pupate in the soil, and the next generation of adults emerges in 2 to 3 weeks. These pests produce up to four generations a year before the final generation of adults settles down for overwintering.

PLANTS THEY ATTACK

Flea beetles attack most vegetables, particularly cabbage-family plants, potatoes, and spinach. They also feed on flowers and weeds.

WHY THEY'RE A PROBLEM

You can recognize flea beetle damage by the small, round holes the adults chew through leaves. These beetles are most damaging in early spring, when heavy infestations can actually kill seedlings. Larger plants usually survive and outgrow the damage, unless they were infected with a plant virus spread by the beetles. Larvae feed on plant roots.

ORGANIC DAMAGE CONTROL

- Plant susceptible plants as late as possible to avoid the most damaging generation.
- Cover seedlings and potato shoots with floating row covers until adult beetles die off.
- Flea beetles prefer full sun, so interplant crops to shade susceptible plants.
- Lightly cultivate the soil around plants before and after planting to destroy any flea beetle eggs and larvae in the soil.
- Flea beetles like to hide in cool, weedy areas. Prevent them from hopping onto your susceptible crops by surrounding the crops with a 3-foot-wide strip of frequently weeded bare ground.
- Confuse the beetles by mixing up your plantings. Surround their favorite food plants with flowers and herbs like Queen Anne's lace, dill, and parsley, which attract beneficial insects.

Imported Cabbageworms

Adult cabbageworms are the common white butterflies you see in everyone's garden. Their wings are white with black tips and one or two small black spots on the forewing. They have a wingspan of 1½ inches. Cabbageworm larvae are velvety green caterpillars with a fine, light yellow stripe down the back. The eggs are tiny yellow cones laid on undersides of plant leaves.

WHERE THEY LIVE

Imported cabbageworms are found throughout North America.

THEIR LIFE CYCLE

Adult butterflies emerge in spring to lay eggs on cabbage-family plants. When the eggs hatch, the caterpillars begin feeding on the undersides of leaves for about 2 to 3 weeks before pupating in garden debris on the soil surface. The butterflies emerge from the pupae in 1 to 2 weeks. Last-generation pupae overwinter in garden debris. These pests produce three to five overlapping generations a year.

PLANTS THEY ATTACK

Imported cabbageworms like to eat nasturtiums, as well as all cabbage-family plants, including broccoli and cauliflower.

A Home for Mr. Toad

Toads eat lots of pest insects, including cucumber beetles, cutworms, grasshoppers, and slugs. But to attract them to your garden, you'll need to provide shelter for them, as well as garden organically. (The porous skin of a toad is very sensitive and will absorb toxins from chemical sprays.)

Here are some things you can do to make sure that the toads that visit your garden have someplace to call home (or at least a place to hide during the day):

- Use lots of mulch. Toads like to burrow into it.
- Turn a broken clay flowerpot upside down; clay absorbs moisture and stays damp and cool, just the way toads like it.
- Arrange rocks so that there's a hollow space inside.
- Grow a fern grove. Ferns do well in moist, shady spots and their leaves create a great foraging spot for toads while providing protection from predators.

WHY THEY'RE A PROBLEM

Cabbageworm caterpillars bite large, ragged holes in cabbage leaves and chew on cauliflower and broccoli florets. They also soil plants with their dark green droppings and tunnel inside heads of broccoli and cauliflower—where they sometimes go unnoticed until (gulp!) it's too late.

ORGANIC DAMAGE CONTROL

- Plant purple cabbage varieties, which are less often attacked by cabbageworms.
- Cover small plants with floating row covers to prevent butterflies from laying eggs on plants.
- Place yellow sticky traps among host plants to catch female butterflies.
- If you don't have too many caterpillars, try handpicking them.
- If you have a severe cabbageworm infestation, spray *Bacillus thuringiensis* var. *kurstaki* (BTK) at 1- to 2-week intervals.
- Clean up all spent plant debris in the fall and dispose of it in order to thwart cabbageworms the following season.

Japanese Beetles

Japanese beetle adults are blocky, metallic blue-green beetles ½ inch long. They have bronze-colored wing covers and their legs

Continued ➔

are relatively long, with large claws. Beetle larvae are fat, dirty white, C-shaped grubs with brown heads, up to ¾ inch long.

WHERE THEY LIVE

These pests are found throughout the Northeast.

THEIR LIFE CYCLE

Adult beetles emerge from late June to July. The beetles feed on plants until late summer, then burrow under grasses to lay eggs. The eggs hatch into larvae that feed until cold weather arrives. As fall approaches, the larvae burrow deeper into the soil to avoid freezing during winter. They move toward the surface again in spring to resume feeding on roots. They pupate in the soil in May and June, so it takes 1 to 2 years for the full life cycle to play itself out.

PLANTS THEY ATTACK

Japanese beetles feed on a variety of vegetables, including beans, corn, and tomatoes, as well as on trees, shrubs, vines, fruits, and flowers. Their larvae damage turfgrass and other grasses.

WHY THEY'RE A PROBLEM

The beetles chew on flowers and skeletonize leaves, which wilt and drop. If you have lots of beetles, they may completely defoliate plants. Beetle larvae feed on roots of lawn turf and other grasses.

ORGANIC DAMAGE CONTROL

- If you notice a lot of beetles during midsummer, cover smaller or more valuable garden plants with floating row covers.
- In the early morning, handpick beetles or shake them from plants onto sheets, and then drown them in a bucket of soapy water.
- Destroy beetle eggs in your lawn by allowing it to dry out well between waterings in midsummer, or stop watering and allow the grass to go dormant for the summer months.
- Aerate the lawn with spiked sandals to kill grubs while they're close to the soil surface in late spring and early fall.
- Apply parasitic nematodes to the lawn in early spring or early fall when the white grubs are in the soil.

Leafhoppers

Adult leafhoppers are mostly wedge-shaped and slender, and range from 1/10 to ½ inch long. Most leafhoppers are either brown or green; some have bright bands of color on their wings. All have well-developed hind legs and can jump rapidly into flight when disturbed. The nymphs are similar to the adults, but paler in color and wingless. They can't fly, but they do hop rapidly when disturbed.

WHERE THEY LIVE

Leafhoppers are found throughout North America.

THEIR LIFE CYCLE

Female leafhoppers start laying eggs when leaves begin to appear on trees. The eggs hatch in 10 to 14 days and the nymphs develop for 1 to 4 weeks before reaching maturity and laying more eggs. The first fall frosts usually kill any remaining nymphs. Adults usually spend the winter on wild host plants; some species overwinter as eggs. Most species have two to five generations a year.

PLANTS THEY ATTACK

Leafhoppers attack flowers, fruit trees, and vegetables, especially apple trees, beans, eggplant, grapes, peanuts, potatoes, and squash-family plants.

WHY THEY'RE A PROBLEM

Both adults and nymphs suck juices from stems and undersides of leaves, giving leaves a light, mottled appearance. Their toxic saliva distorts and stunts plants and causes tip burn and yellowed, curled leaves. If you have a lot of leafhoppers, they may stunt the growth of entire plants. Leafhoppers also spread viruses.

ORGANIC DAMAGE CONTROL

- Control nymphs while they're still small by spraying them with insecticidal soap or by washing them from plants with strong sprays of water.
- Cover plants with floating row covers.
- Grow pollen- and nectar-producing plants like goldenrod and yarrow to attract beneficials, such as lady beetles.
- Healthy plants can often tolerate some leafhopper feeding, so keep a watchful eye on susceptible crops and action may not be necessary.
- When possible, grow resistant varieties. For example, certain species of leafhoppers avoid beans and potatoes with fuzzy leaves.

Leafminers

Leafminers are mostly black or black and yellow flies. They're incredibly small (1/10 inch long), so you've probably never even seen one. Their larvae are pale green, stubby, translucent maggots, found in tunnels between the upper and lower surface of leaves. The eggs are white and cylindrical, and they lay side by side in clusters on leaf undersides.

WHERE THEY LIVE

These pests are found throughout North America.

THEIR LIFE CYCLE

Adult flies emerge from overwintering cocoons in early spring and lay eggs on leaves. The larvae mine in the leaf tissue for 1 to

3 weeks, then pupate for 2 to 4 weeks. Most species of leafminers have two or three generations a year.

PLANTS THEY ATTACK

Leafminers attack beets, cabbage, chard, lettuce, peas, peppers, spinach, and tomatoes. They're also a problem on trees, ivy, and flowers—especially chrysanthemums and nasturtiums.

WHY THEY'RE A PROBLEM

Larvae tunnel through leaf tissue and may damage the leaves enough to destroy seedlings. On older plants, though, leafminers are often more of a nuisance than a serious problem. Leafminer damage is also unsightly on ornamentals.

ORGANIC DAMAGE CONTROL

- Cover seedlings with floating row covers to prevent adults from laying eggs.
- Keep row covers on all season on small plants, like beets and chard, where leafminers really like to hang out and eat.
- Remove any nearby dock or lamb's-quarters, which are wild hosts for the beet leafminer.
- In spring, handpick and destroy damaged leaves and egg clusters, which will help reduce later generations.

Natural Predators

Spined soldier bugs, green lacewings, and syrphid flies all enjoy snacking on the small larvae or eggs of imported cabbageworms. Here are some things you can do to attract each of these good guys.

Spined soldier bugs. Grow pollen-providing plants (adults like to hang out on the flowers of goldenrod, hydrangeas, and milkweed). Maintain undisturbed areas near your garden.

Green lacewings. Grow angelica, caraway, cosmos, dandelion, dill, goldenrod, sunflowers, and sweet alyssum. Provide water in a pan filled with gravel—especially during dry spells—so the delicate insects can alight on the gravel and drink without drowning.

Syrphid flies. Grow pollen and nectar plants, especially sweet alyssum and wild mustard. Allow some broccoli to flower. Landscape with tall plants like sunflowers that break the wind so syrphid flies can hover undisturbed.

- Tiny parasitic wasps help to keep leafminer populations under control. Attract these beneficial predators into your garden by making sure that you have lots of flowers blooming throughout the season.
- Keep plants well watered throughout the growing season. Plants suffering from inadequate moisture are more susceptible to leafminer damage.

Mexican Bean Beetles

Adults are oval, yellowish brown to copper-colored beetles, ¼ inch long. They have 16 black spots arranged in three rows across their wing covers and look a lot like lady beetles (which are good guys). The beetle larvae are fat, legless, yellowish orange grubs up to ⅓ inch long. They have six rows of long, branching spines on their body. Eggs are bright yellow ovals laid on end in clusters of 40 to 60 on undersides of leaves.

WHERE THEY LIVE

These pests are found throughout North America, except in the Pacific Northwest.

THEIR LIFE CYCLE

Adult beetles start to emerge about the time the first bean leaves are up, and more continue to straggle out of hibernation over the next few months. The beetles feed for a couple of weeks before the females lay eggs on bean plants. After the eggs hatch (in about 5 to 14 days), the larvae feed for 2 to 5 weeks, pupate, and then the beetles emerge about a week later. Mexican bean beetles produce up to four generations a year, with adults overwintering in garden debris or leaf litter.

PLANTS THEY ATTACK

Bean beetles damage all kinds of beans, including cowpeas, lima beans, snap beans, and soybeans.

WHY THEY'RE A PROBLEM

Larvae and adults skeletonize leaves, leaving behind a characteristic lacy appearance. Attacked plants may produce fewer pods and may be completely defoliated and killed in July and August when beetles are most numerous.

ORGANIC DAMAGE CONTROL

- If you notice Mexican bean beetles in your garden, don't panic. Experts have found that bean plants can tolerate up to 50 percent defoliation and still produce a good crop.
- Plant resistant bean varieties.
- In the South, plant early-season bush beans to avoid damage.
- Cover young plants with floating row covers.
- Leave a few flowering weeds between rows, or interplant your garden with herbs and flowers to attract native predators and parasites.

Continued →

- Remove or dig in crop debris after harvest to remove overwintering sites.
- Handpick larvae and adults daily.
- Toads love to eat bean beetles. Attract these hungry bug eaters into your garden by providing areas of moist shade.

Peachtree Borers

These unusual moths have narrow, clear wings with 1¼-inch wingspans. They have a blue-black body, and males have narrow yellow bands around the body. The larvae are white grubs, up to 1 inch long, with dark brown heads.

WHERE THEY LIVE

Peachtree borers are found throughout North America.

THEIR LIFE CYCLE

Peachtree borers have an unusual life cycle. In July and August, female moths emerge from the soil to lay eggs on trees or soil close to the trunk. The eggs hatch in 12 days and larvae bore under the bark at ground level, where they overwinter before resuming feeding in the roots in spring. The larvae pupate in silken cocoons in the soil by late June or July, usually within a few inches of the trunk.

PLANTS THEY ATTACK

These borers attack mainly peach trees; they also occasionally attack apricot, cherry, nectarine, plum, and prune trees.

WHY THEY'RE A PROBLEM

Because peachtree borer larvae bore beneath the bark at the base of trees and into the main roots near the surface, they often girdle trees. Their entrance holes are filled with a gum mixed with sawdust. Young or weakened trees may be seriously damaged or killed, whereas older and more vigorous trees that are better established are less likely to be adversely affected.

ORGANIC DAMAGE CONTROL

- Avoid injuries to tree bark from lawn mowers and other pieces of equipment, as adult moths are attracted to injured trees.
- Inspect tree trunks in late summer and remove soil several inches deep around the base of each trunk to look for borer holes containing larvae. Dig out the larvae with a sharp knife or kill them by working a flexible wire into the holes.
- Cultivate the soil shallowly around the trunk to destroy pupae.
- Studies have shown that parasitic nematodes can reduce borer damage by as much as 66 percent. Spray these microscopic beneficials around the trunk of the tree near the soil line in late April. The nematodes will seek out the peachtree borers and parasitize them, releasing a lethal bacteria as they feed.

Soft Scales

Female soft scales are tiny oval or round, legless, wingless bumps. Males are minute, yellow-winged insects. The youngest larvae are tiny crawlers resembling minute mealybugs, while older larvae settle and become sedentary.

WHERE THEY LIVE

You'll find scales throughout North America.

THEIR LIFE CYCLE

Females of some species lay as many as 2,000 eggs, while others give birth to several nymphs per day. Nymphs move around on the plants for a short time, then settle in place to feed. Scales residing outdoors may produce one or two generations a year, while indoor populations may produce up to six generations.

PLANTS THEY ATTACK

Soft scales attack citrus and other fruit trees, as well as ornamental shrubs, trees, and many types of houseplants.

WHY THEY'RE A PROBLEM

All stages of scales weaken plants and cause leaves to yellow and drop by sucking sap from them. If you have a severe infestation, your plant may die. Soft scales also secrete a sticky substance called honeydew on leaves and fruit as they feed. (Certain species of ants feed on the sticky honeydew—and these ants will actually protect the scale to preserve their food supply.) Sooty mold, a black fungus, grows on the honeydew.

ORGANIC DAMAGE CONTROL

- Attract native parasites and predators to your garden. Tiny parasitic wasps and lady beetles are particularly helpful in controlling scale. So if you have infested houseplants, move them outside for the summer, and let these beneficials clean them up for you.
- Scrub scales gently from twigs with a soft brush and soapy water, or a cloth dipped in insecticidal soap, then rinse well.
- Spray affected plants (including fruit trees) with horticultural oil. (Spray during dormant season when beneficial insects aren't active.)
- Prune and destroy branches and twigs that are significantly infested.
- Wash scale off plants with a strong spray of water from your garden hose. Be sure to hit the undersides of leaves, too.
- Keep your plants healthy. This includes enriching the soil with compost and watering adequately.

Slugs and Snails

Snails carry coiled shells on their backs, while slugs have no shells. Common species of slugs and snails are ⅛ to 1 inch long. (Banana slugs found in coastal areas stretch from 4 to 6 inches

long.) Slugs and snails are gray, tan, green, or black, and some have darker spots or patterns. They leave a characteristic slimy trail of mucus behind. Their eggs are clear, oval, or round and are laid in jellylike masses under stones in the garden.

WHERE THEY LIVE

You'll find these slimers throughout North America.

THEIR LIFE CYCLE

Adults lay eggs in moist soil, and the eggs hatch in 2 to 4 weeks. Slugs can grow for up to 2 years before reaching maturity.

PLANTS THEY ATTACK

Slugs and snails attack any tender plants, although slugs in particular have a taste for vegetables. Snails can be a serious problem on citrus.

WHY THEY'RE A PROBLEM

Both slugs and snails feed primarily on decaying plant material. But they also eat soft, tender plant tissue and make large holes in foliage, stems, and even bulbs. They may completely demolish seedlings and severely damage young shoots and plants. They may also crawl up trees and shrubs to feed. Both are most numerous and damaging in wet years and in regions that receive lots of rain.

ORGANIC DAMAGE CONTROL

- Garden organically so that your landscape is a welcome home for many natural enemies of slugs, including birds, garter snakes, toads, and lizards.
- Maintain permanent walkways of clover, sod, or stone mulches to encourage predatory ground beetles.
- Repel slugs and snails with copper strips fastened around trunks of trees or shrubs.
- Edge garden beds with copper flashing or screening (make sure you've removed all the slugs first).
- Protect seedlings temporarily by spreading wide bands of cinders or wood ashes on the soil.
- Set out traps such as pots, boards, or overturned grapefruit rinds; check the undersides of the traps every morning and destroy the slugs you find.
- Bury tin cans with the lip flush to the soil surface and fill the traps with beer to attract slugs. The slugs will fall into the beer and drown.
- Encircle tender young seedlings with a protective barrier of crushed eggshells.

Spider Mites

Spider mites are incredibly tiny—less than 1/75 to 1/50 inch long. Adults have eight legs and are reddish, pale green, or yellow and have fine hairs on the body. Some have a darker patch on each side. Most species spin fine webs on plant leaves and shoots. Spider mite eggs are minuscule pearly spheres found on webbing or on leaf hairs.

WHERE THEY LIVE

Spider mites make their homes throughout North America.

THEIR LIFE CYCLE

Eggs hatch in 1 to 8 days, and nymphs develop into adults in 5 to 10 days. Outdoors, eggs or adults overwinter in crevices in bark or in garden debris. These pests have a short life cycle and may reproduce year-round on indoor plants.

PLANTS THEY ATTACK

Many vegetables, fruits, and herbs fall prey to spider mites.

WHY THEY'RE A PROBLEM

Both adults and nymphs suck the juice from plants on the undersides of leaves. If you have a lot of spider mites, their feeding weakens plants, causes leaves to drop, and results in stunted fruit. The first signs of damage are yellowed speckled areas on leaves. In severe infestations, leaves become bronzed or turn yellow or white with brown edges. The webs may cover both sides of the leaves and eventually cover the tips of branches. Spider mite outbreaks can be sudden and severe in hot, dry conditions. When humidity is low, spider mites feed more to avoid drying up, which drives them to lay more eggs, speeding up their development.

Oriental Fruit Moth

Adult oriental fruit moths are small, dark gray moths that lay eggs on fruit trees in spring. Their larvae are white to pinkish gray caterpillars with brown heads. The caterpillars bore into twigs of fruit trees early in the season, causing them to wilt and die. In midsummer, caterpillars bore into developing fruit. Late-summer caterpillars enter the stem end of maturing fruit and bore into the pit.

The larvae overwinter in cocoons on tree bark or in weeds or soil around the trees. They pupate in early spring, and the moths emerge from early May to mid-June to lay eggs.

You can help prevent the oriental fruit moth from getting the better of your fruit trees by planting peach and apricot varieties that bear fruit before midsummer. To destroy overwintering larvae, cultivate the soil 4 inches deep around unmulched trees in early spring. Pick and destroy immature, infested fruit, and spray summer oil to kill eggs and larvae.

Continued →

ORGANIC DAMAGE CONTROL

- Knock off spider mites with a strong spray of water. Be sure to spray the undersides of leaves, which is where the mites like to feed.
- Maintain high humidity around houseplants and plants in greenhouses.
- Spray dormant oil on fruit trees to kill overwintering spider mite eggs.
- Keep plants well-watered throughout the growing season; moisture-stressed plants are more vulnerable to spider mite attacks.
- Spray infested plants with horticultural oil.

Squash Bugs

Adults are oval, dark brown to black, and very tiny. Their abdomen is flattened and covered with fine, dark hairs. They give off an unpleasant smell in self-defense. The youngest nymphs are pale green, while the older ones are covered with what looks like a grainy gray powder. Squash bug eggs are shiny yellow, turning brick red as they mature, and are laid in groups on the undersides of leaves.

WHERE THEY LIVE

You'll find squash bugs throughout North America.

THEIR LIFE CYCLE

Female bugs lay eggs in spring. The eggs hatch in 1 to 2 weeks, and the nymphs take 4 to 6 weeks to develop. Adults overwinter under garden debris, vines, or boards. Squash bugs produce one generation a year.

PLANTS THEY ATTACK

These pests prefer cucumbers, melons, pumpkins, squash, and gourds.

WHY THEY'RE A PROBLEM

Both adults and nymphs suck plant juices, which causes leaves and shoots to blacken and die. Severely attacked plants may not produce any fruit.

ORGANIC DAMAGE CONTROL

- Plant resistant squash varieties.
- Handpick eggs, nymphs, and adults from the undersides of leaves.
- Support vines off the ground with trellises.
- Place boards on the ground next to plants in early summer and destroy adults found under the boards every morning.
- Tachinid flies will parasitize up to 80 percent of squash bugs in a given area. The flies, which are found throughout most of the United States, lay their eggs on the squash bugs, then their larvae emerge inside the body of the squash bug. Don't kill any squash bugs that you notice carrying little white eggs since the eggs will hatch into more tachinid flies. Attract the adult flies by planting dill, parsley, sweet clover, fennel, buckwheat, goldenrod, wild carrot, or amaranth.
- Remove overwintering sites by cleaning up the garden in fall.
- Protect young seedlings with row covers until the plants are large enough to sustain some damage and still produce a crop.

Tarnished Plant Bugs

Tarnished plant bug adults are quick-moving, oval bugs that are ¼ inch long. They're a mottled light green to coppery brown and their top wings have a black-tipped yellow triangle on each side. Nymphs are yellowish green with five black dots on the body, similar to adult bugs, but wingless. Tarnished plant bugs lay their eggs into plant stems or leaves.

WHERE THEY LIVE

These bugs make their homes throughout North America.

THEIR LIFE CYCLE

Adults emerge in early spring to feed on fruit buds and other early foliage. They move to garden plants or weeds, such as clover, chickweeds, and dandelions, to lay eggs. The eggs hatch in 10 days; nymphs feed for about 3 weeks, then molt to adults. Tarnished plant bugs produce up to five overlapping generations a year; the adults overwinter under fallen leaves.

Scales of Armor

Armored scales are similar to soft scales, except that they are mostly found in the Deep South, Southwest, and California—and they have waxy armor. Adults are tiny round or oval hard bumps, with no visible head or legs. These scales secrete an armor of wax in an oyster shell or circular shape. Depending on the species, they can be ashy gray, yellow, white, reddish, or purplish brown. The early stage nymphs are mobile crawlers, while later stages are legless and hardly move. In the South, armored scales are serious pests of citrus, but they also attack palms, roses, and tropical ornamentals. In the North, they infest fruit and shade trees, currants, grapes, raspberries, and ornamental shrubs. To combat armored scales, apply dormantoil sprays during winter. You can also try summer oil on plants that tolerate it.

PLANTS THEY ATTACK

Most flowers, fruits, vegetables, and weeds are food for tarnished plant bugs.

WHY THEY'RE A PROBLEM

Both adults and nymphs suck the juice from leaves, buds, and fruit. Their toxic saliva causes buds and pods to drop and distorts leaves and shoots. Parts of plants wilt or are stunted, and branch tips blacken and die back. Feeding on tomatoes and other fruit causes pitted catfacing on the fruit, while feeding on broccoli and cauliflower leaves dead spots on florets.

ORGANIC DAMAGE CONTROL

- Cover plants with floating row covers, especially if you have a lot of tarnished plant bugs.
- Keep your garden free of weeds and dead plant debris, and make sure to remove spent plants at the end of the season.
- Grow pollen and nectar plants, such as sweet alyssum, daisies, and cosmos, to attract native predatory bugs such as big-eyed bugs and minute pirate bugs, which feed on nymphs.
- In vegetable gardens, plant cool-season cover crops like subterranean clover. These cover crops attract big-eyed bugs, one of tarnished plant bugs' natural enemies.

Thrips

Adult thrips are minute—about 1/50 to 1/25 inch long. They're yellowish brown or black and have narrow, fringed wings. They move quickly and like to hide in tight crevices in plant stems and flowers. Nymphs are light green or yellow and look similar to adults, but smaller.

WHERE THEY LIVE

You'll find thrips throughout North America.

THEIR LIFE CYCLE

Adults become active in early spring and lay eggs in plant tissue. The eggs hatch in 3 to 5 days, and the nymphs feed for 1 to 3 weeks before molting to the adult stage. Thrips produce many generations a year and breed year-round in greenhouses; adults overwinter in sod, debris, or cracks in bark.

PLANTS THEY ATTACK

These bad bugs attack asparagus, cabbage, lettuce, onions, peas, flowers, and fruit and shade trees.

WHY THEY'RE A PROBLEM

Both adults and nymphs suck the contents of plant cells. In severe infestations, they leave plants stunted and distorted and flowers damaged. Some species spread tomato spotted wilt virus.

ORGANIC DAMAGE CONTROL

- Plant pollen and nectar plants and provide a water source in your garden to attract predators such as lacewings and lady beetles.
- Spray dormant oil in early spring to control thrips attacking fruit trees.
- Use bright blue or yellow sticky traps to catch adults in greenhouses.
- Wash thrips off with a strong spray of water from your garden hose.

Whiteflies

Adult whiteflies are tiny, powdery-white insects, 1/20 inch long. Although their name suggests that they're related to flies, they really aren't—they're related to aphids. Whiteflies rest on the undersides of leaves and fly up when they're disturbed. Nymphs are tiny, flattened, translucent scale also found on the undersides of leaves. The eggs are gray or yellow cones the size of a pinpoint.

WHERE THEY LIVE

Whiteflies are a pest throughout North America.

THEIR LIFE CYCLE

The complete whitefly life cycle takes only 20 to 30 days at room temperature. The eggs hatch in 2 days into tiny scales; the

Squash Vine Borers

Another pest that attacks squash family plants is the squash vine borer, which is found throughout North America (except for the West Coast). Adults, which are narrow-winged, olive brown moths, lay eggs on stems near the bases of plants. The larvae are white grubs with a brown head and bore into squash vines. The vines wilt suddenly, and girdled vines rot and die. The larvae may also feed on fruit later in the season.

Squash vine borer larvae or pupae overwinter in the soil. Adults emerge as squash vines begin to lengthen and then lay their eggs on stems and leaf stalks. The larvae burrow into stems for 4 to 6 weeks, then pupate in the soil for winter. These pests usually produce only one generation a year.

Control borers by planting early or late to avoid the main egg-laying period. Also fertilize plants to promote vigorous growth so the vines are better able to tolerate borer attacks.

Continued →

scales feed on plant juices before molting to adults. These bugs produce many overlapping generations a year, continuing all winter in greenhouses and warm climates. In cold winter areas, whiteflies can't survive outdoors in winter. However, they can reinfest gardens each spring if they're brought in on infested transplants from commercial greenhouses and nurseries.

PLANTS THEY ATTACK

Whiteflies attack citrus plants and many vegetable crops, especially squash and tomato family plants.

WHY THEY'RE A PROBLEM

Both nymphs and adults suck plant juices, weakening plants. They can spread plant viruses through their feeding. They also exude honeydew, which supports the growth of sooty molds on leaves and fruit.

ORGANIC DAMAGE CONTROL

- Capture adult whiteflies on yellow sticky traps.
- Use a handheld vacuum to suck up adults from the undersides of leaves (you can do this if the infestation isn't too severe).
- Control nymphs with insecticidal soap.
- Wash the sticky coating from leaves with water.
- Smother whiteflies with a spray of horticultural oil. Spray during the cool times of the day since the oil can react with sunlight and damage plant leaves.
- Attract wasps that parasitize whiteflies into your garden by providing food and shelter. Parasitic wasps feed on the nectar of parsley, dill, Queen-Anne's lace, daisies, sunflowers, and coneflowers. Grow tall plants like corn and sunflowers to protect these tiny fliers from the wind.

Potions and Practices for Organic Pest Control

Joan Benjamin and Deborah L. Martin

On any warm summer day, your garden is filled with flying, crawling, and jumping insects. But very few of these creatures are plant pests. Most of them—including spiders, lady beetles, and many wasps and flies—are more interested in capturing other insects than in aggravating gardeners. So controlling the few insects that are pests really isn't hard. Organic gardeners have devised lots of useful sprays, barriers, and traps for controlling pests without chemical pesticides.

Pest insects usually have specific food requirements. Many of the pest control formulas in this chapter work by tricking pests into thinking that they are on the wrong plant or making them eat something that they can't digest.

You'll also find formulas in this chapter for bigger pests, like squirrels, deer, cats, and dogs. These pesky animals can frustrate gardeners by eating or trampling plants. But, although we don't want animals to hurt our gardens, we also don't want to hurt the animals, so all of the formulas you'll find here are strictly nonpoisonous. They work by conditioning animals to look elsewhere for dinner.

Use these same approaches when developing your own formulas to solve unusual pest problems in your garden. For example, if you have a problem with an insect that eats one type of plant but is never seen on another, try planting the two types of plants close to each other to confuse the pest and lessen the damage. Or you might brew a tea from leaves of the plant the pest ignores and use it to drench the plant that the pest likes. It just might fool them!

Pest Patrol Bucket Blend

No insect prisoners can escape when you hand-pick pests and toss them into this easy-to-mix blend of soap, oil, and water. In her garden near Fenelon Falls, Ontario, Mary Perlmutter, author of *How Does Your Garden Grow... Organically?*, takes this blend along on pest patrol every morning to dispatch any pesky insects like Japanese beetles, Colorado potato beetles, and tomato hornworms that she finds attacking her plants.

Ingredients and Supplies

1 quart water (approximately)

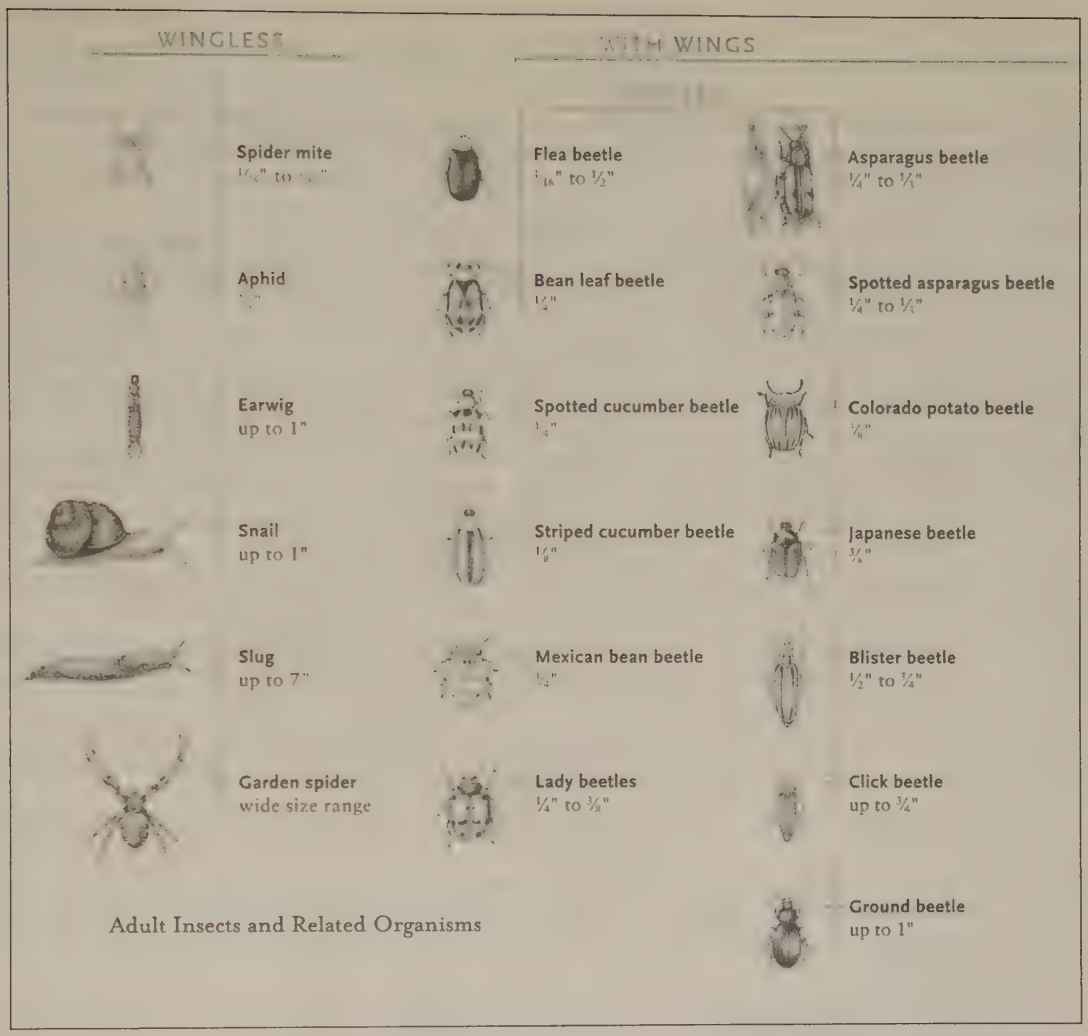
1 small bucket or pail

1 teaspoon dishwashing liquid

2 tablespoons cooking oil (any type)

Discover the World's Safest Insecticide: Water!

It may be tempting to bring out the arsenal when you find your favorite rosebush infested with aphids, but a safer and less-expensive solution is as close as the end of your hose—water! Researchers at Texas A&M University have been able to knock out 70 to 90 percent of aphid infestations by spraying water through a specially designed hose. A strong shot of water will wash away spider mites and thrips, too! You don't necessarily need a high-tech wand on the end of your hose, though; you can achieve good results using an ordinary watering wand. Just make sure to spray both the upper and lower sections of the leaves. Once those pests hit the ground, it's very difficult for them to make it back onto your plants.



Adult Insects and Related Organisms

Directions

1. Put 2 to 3 inches of water in the bucket or pail.
2. Add dishwashing liquid and oil and mix. The oil will float to the top, where it will remain as small droplets.
3. Gather unwanted insects from your garden, tossing the pests into the mixture as you go.

Yield: About 1 quart of pest-killing mixture

Note: "The oil means they have no hope of being able to crawl back out," Mary reports. Caterpillars quickly sink to the bottom of the soap-oil mix, and Colorado potato beetles swim for only a few seconds. The dishwashing liquid in this blend helps keep the oil mixed into the water. By breaking down an insect's outer covering, or cuticle, it also speeds the demise of the pests you toss into your bucket.

Mary often uses the same mixture for several days. When she's finished with the liquid, she pours it onto her slow compost pile (where she puts tree prunings and other organic materials that break down slowly).

Your First Defense Against Pests

If you spot insect pests on a plant, simply pick them off! Then dispense with the pests using two flat rocks or whatever squashing method you can think up.

If the pests are too small, fast, or numerous for hand-picking, take action right away with an appropriate pest control formula. Pest populations tend to build up very quickly, and it's always easier to control a pest problem the day you discover it than to wait for another day—by then, you may face double the problem.

Continued →

Plants That (May) Keep Pests Away

Sally Jean Cunningham

Here's a listing of companion plants reputed to repel garden pests. Choose some of them as plant friends for your vegetable families. Many of these recommendations are based on tradition and folklore alone, so don't rely too heavily on them for pest protection. Experiment for yourself. You may find that some of these plants do a great job in your garden.

Companion Plant	Pests Repelled	Companion-Garden Uses
Basil	Aphids, asparagus beetles, mites, mosquitoes, tomato hornworms	Plant next to paths where you'll brush it often, releasing the aromatic oil that may confuse pests; try it along the edge of asparagus beds and among tomatoes and eggplants
Borage	Tomato hornworms	Plant with tomatoes, and let it self-sow throughout the garden to attract beneficial bees and other insects
Calendula	Asparagus beetles	Definitely attracts beneficials, so plant throughout the garden as well as by your asparagus
Catnip	Aphids, asparagus beetles, Colorado potato beetles, squash bugs	Catnip's repellent qualities are backed by research; can spread uncontrollably, so plant in pots and place them near or among peppers, potatoes, tomatoes, and vine crops
Chives	Aphids, Japanese beetles, probably many insects	Excellent perennial herb to place around roses, raspberries, grapevines—or wherever Japanese beetles are a problem
Garlic	Japanese beetles, many other pests	Plant around roses or other flowers that suffer from Japanese beetles, especially in a cutting garden; or mix a spray from crushed garlic and water
Zonal geraniums	Japanese beetles	Tests show these flowers, especially white-flowered types, repel and even kill Japanese beetles; try among roses or other crops that Japanese beetles favor; may also work as a trap crop by attracting the beetle
Horseradish	Colorado potato beetles	Not a practical companion for potatoes, because it's a spreading perennial; plant among other permanent plantings, such as asparagus, raspberries, strawberries, and perhaps rhubarb Cabbage moths
Hyssop	Cabbage moths	Some studies back this claim; try planting among broccoli, brussels sprouts, cabbage, and cauliflower
Marigolds	Mexican bean beetles, root-knot nematodes, root lesion nematodes	Strong evidence supports repellent qualities for nematodes; plant a solid block in nematode-infested areas; at flowering, chop and turn under entire crop
Mints	Aphids, cabbage moths, possibly other pest insects	Very invasive; surround with a solid root barrier or grow in pots
Nasturtiums	Aphids, Colorado potato beetles, Mexican bean beetles, squash bugs	Studies show conflicting evidence; plant with vine crops to protect ground beetles and spiders and to act as a pretty living mulch
Onions	Carrot rust flies	Research backs interplanting with carrots to repel rust flies; intermingle the crops or plant clusters or strips of onions and carrots side by side
Parsley	Asparagus beetles	Plant on the edges of asparagus beds; it often survives over winter; let some go to flower to attract beneficials
Radishes	Cucumber beetles	There's some evidence that radishes do confuse cucumber beetles; plant three to five seeds in every "hill" or cluster of cucumber plants; also plant among squashes and pumpkins
Rosemary	Cabbage moths, carrot rust flies, Mexican bean beetles	Plant among beans and cabbage family crops, or beside lettuce and carrot combinations
Rue	Japanese beetles	Traditional reports also list rue as a growth inhibitor for some plants; not practical except among plantings of perennials; caution: touching the foliage may cause allergic reaction
Sage	Cabbage moths, carrot rust flies, others	Include in a perennial herb or flower border
Savory	Mexican bean beetles	Plant on the edges of tomato/bean plantings or in perennial herb areas around the garden
Southern-wood and wormwood	Flea beetles, mosquitoes	Plant in perennial clusters or herb borders near or beside the garden, and use them near areas where people congregate (we rub them on our skin as mosquito repellents)
Tansy	Colorado potato beetles, squash bugs	Some tests support tansy as a repellent, but the best reason to plant is to attract beneficial insects
Thyme	Cabbage moths	Studies back this claim: plant near cabbage family crops or in any perennial/herb combination near the vegetable garden; creeping thymes are excellent groundcovers for permanent plantings

HATE TO HAND-PICK?

Many gardeners are squeamish about handling insects with their bare hands. If you're averse to plucking pests with your fingers, try using disposable latex gloves when you go on pest patrol. Your hands will stay clean, and you'll still have enough dexterity to nab the pests. Another option when your prey is slow-moving, like slugs, is to pick up the pests with chopsticks. You can also shake pests like Colorado potato beetles and Japanese beetles off of plants and directly into your bucket of oily soap mixture.

Paralyzing Pest Salsa

Paralyze pests with salsa that's only a little stronger than you might eat on your chips. The creator of this formula, Santa Barbara gardener and author Kathleen Yeomans, uses it to control pests ranging from ants to black widow spiders.

"This is my favorite all-purpose insect spray," Kathleen says. According to Kathleen, the spray will make ants pass out cold, and it has actually killed a black widow spider.

Ingredients and Supplies

- 2 pounds ripe, blemished tomatoes
- 1 large onion
- 1 pound fresh chili peppers
- 2 cloves garlic
- Food processor or blender
- 1 cup vinegar
- ½ teaspoon pepper
- Cheesecloth or coffee filter
- Pump spray bottle

Directions

1. Roughly chop the tomatoes, onion, peppers, and garlic.
2. Place the chopped vegetables in a food processor or blender and blend until liquefied.
3. Add vinegar and pepper to the mixture.
4. Strain the mixture through several layers of cheesecloth or a disposable coffee filter.
5. Pour the strained liquid into the pump spray bottle.
6. Spray the liquid directly on pests that you spot in your garden.

Yield: About 3 cups of insect-knockout salsa

Note: Crushed garlic contains allicin, the smelly compound that confounds the sensory receptors of insects in search of a tasty plant feast. Hot peppers are loaded with fiery capsaicin, which gives a chemical burn to marauding mammals and some soft-bodied insects. Onions help give the salsa an extra aromatic kick, and the sulfur in them may suppress some fungal diseases. Many pests avoid tomatoes, so the unmistakable tomato odor signals them to look elsewhere.

Caution: This salsa can be highly irritating if it gets in your eyes or mouth, so spray it only on a windless day.

Pest-Puzzling Garlic Extract

Garlic has a perplexing effect on a wide range of garden pests, from aphids to Mexican bean beetles. This formula for garlic extract comes from David Stern, an organic farmer and director of the Garlic Seed Foundation in Rose, New York. Garlic extract probably works by confusing insects in search of their favorite host plants, so for maximum effectiveness, spray before any pests have become a serious problem.

Ingredients and Supplies

- ¼ pound garlic (2–3 whole garlic bulbs)
- 1 quart water
- 4–5 drops dishwashing liquid
- Blender or food processor
- Cheesecloth
- 1-quart glass jar

Directions

1. Separate the garlic bulbs into cloves but do not peel them.
2. Place the whole garlic cloves in a blender or food processor with 1 cup of the water. Chop well. If you have lots of garlic plants, you can use garlic leaves instead of cloves. The chopped leaves also contain allicin, one of the pest-repelling ingredients in garlic.
3. Add the rest of the water and the dishwashing liquid. Blend until liquefied. (This usually takes several minutes.)
4. Strain the mixture through cheesecloth to remove bits of garlic that might clog the sprayer. It's a good idea to strain a second time if any debris remains in the concentrate.
5. Store the strained concentrate in a glass jar with a tight fitting lid until you are ready to use it.

Yield: About 1 quart of concentrated garlic extract

Note: To make a spray from the concentrated extract, dilute 1 part extract with 10 parts water (¼ cup concentrate to 2½ cups water). Put the diluted extract in a pump spray bottle or pressure sprayer and apply to plants that are under pest attack or that you suspect are likely targets, like young bean and potato plants. David points out that you can also apply the garlic extract to the soil to discourage nematodes.

Continued ➔

GOOD BUGS DON'T LIKE GARLIC

Be selective when you spray your plants with garlic extract. Even though it's organic, it can disrupt or even kill helpful insects like syrphid flies and lacewings which prey on pest insects.

Citrus Killer for Aphids

Pesky insects go into convulsions when doused with citrus oil extract. This mixture quickly neutralizes aphids and other soft-bodied insects in the California garden of Kathleen Yeomans, author of *The Able Gardener*. She also uses it to deter ants. "The spray will keep ants away for a while, but they may come back," Kathleen observes. But since this mixture has such a refreshing smell, you'll probably enjoy using it often.

Ingredients and Supplies

- 1 pint water
- Rind from 1 lemon, grated
- Cheesecloth
- Pump spray bottle

Directions

1. Bring the water to a boil. Remove from heat and add the grated lemon rind.
2. Allow the mixture to steep overnight.
3. Strain the mixture through cheesecloth, and pour into the pump spray bottle.
4. Apply the mixture to plant leaves that are under attack by aphids or other soft-bodied insects. The mixture must come in contact with the insects' bodies to be effective.

Yield: About 1 pint of citrus oil extract

CITRUS SUBSTITUTES

Lemon isn't the only source for a citrus spray. You can make a similar spray using orange or grapefruit rinds. Richard Merrill, director of horticulture at Cabrillo Community College in Santa Cruz, California, has tried several kinds of citrus sprays on aphids. "Citrus fruits with pungent rinds work best, since they probably include more limonene and linalool, which are the active ingredients," he says. For example, a navel orange with a mild, sweet rind would probably not carry the punch of a spray made from the rind of a sour orange, grapefruit, or lemon.

Hot Spray for Flea Beetles

Shoo away pesky flea beetles by dousing plants with a potent mixture of garlic and hot pepper. Pennsylvania market gardener Cass Peterson uses this mixture to keep flea beetles from feeding on her spring broccoli and cabbage.

Ingredients and Supplies

- 6 cloves garlic
- Hammer
- 1-quart glass jar with lid
- 1 tablespoon powdered or crushed hot pepper
- 1 quart warm water
- Cheesecloth
- Pump spray bottle

Directions

1. Smash unpeeled garlic cloves with a hammer.
2. Put the crushed garlic in the glass jar.
3. Add the hot pepper and warm water. Screw on the lid.
4. Shake up the mixture.
5. Set the jar in the sun to steep for 2 days or longer. "If you pop off the lid to take a sniff and your eyes water, it's ready," Cass says.
6. Strain the mixture through the cheesecloth and pour the liquid into a pump spray bottle.

Yield: About 1 quart of garlic pepper spray

Note: Apply the garlic pepper spray as soon as you see flea beetles, and reapply it after rains or heavy dew. Since flea beetles feed on both sides of plant leaves, make sure that the plants are thoroughly drenched. As with any water-based spray, this mixture can damage plant leaves if applied in the middle of a hot, sunny day.

Cass suggests starting a new batch of spray every few days in late spring, when flea beetles are at their worst. Work outdoors, where you won't mind the mess and smell. If a hammer isn't handy, Cass smashes the garlic with a brick, piece of wood, or the palm of her hand.

Variation: You can use any type of pepper for this mix as long as it's really hot. Since Cass grows a variety of hot peppers, she picks whatever type is plentiful. Cayenne pepper or crushed pepper flakes, available on the spice shelf at the supermarket, work equally well and make a convenient substitute for crushed whole pepper.

New York–Style Slug Bait

Stop slugs dead with a do-it-yourself slug saloon. At Cornell University in Ithaca, New York, Dr. Marvin Pritts has studied beers, nonalcoholic beers, and various yeast-sugar mixtures to trap slugs in strawberries. In the strawberry fields where he conducted his research, beer attracted many more slugs than the other mixtures did. The slugs didn't care for plain sugar and water; they wanted beer—nonalcoholic as well as

regular beer—and they weren't fussy about the brand! "We looked at many different brands, and there really wasn't much difference," Marvin says.

Ingredients and Supplies

2 roofing shingles
1 heavy knife or utility shears
6 shallow containers such as quart jar lids
1 can or bottle of any brand of beer, nonalcoholic or regular
1 pail or bucket

Directions

1. Cut roofing shingles into three 1-foot-square pieces.
2. Fold the squares in half to form covers for your slug traps.
3. Settle the edges of the covers into the mulch or soil near plants that are being damaged by slugs.
4. Fill containers to the rim with beer. Slide the containers under the covers and leave them in place.
5. After 1 or 2 days, empty the trapped slugs and old beer into a pail or bucket.
6. Refill the traps with more beer.

Yield: 6 slug traps

Note: Marvin says to check the undersides of the covers, too. Slugs may be hiding there, waiting for their chance at the beer. All of the slugs that actually make it into the traps will be dead, but the late arrivals may still be alive.

Ailing Slug "Ale"

If there's one pest that every gardener loves to hate, it's a slug. Slugs can ruin tender young vegetables and beautiful flower gardens in just a few nights' feedings. But slimy slugs will drink themselves to death when you offer them this aromatic brew concocted by Carl Elliot, garden coordinator for Seattle Tilth's demonstration garden.

Any time is a good time to get rid of garden slugs, but Carl says to be especially vigilant in the fall. That way, there will be fewer slugs around in the spring, when your garden is brimming with the young, tender plants that slugs like best.

Ingredients and Supplies

1 quart unpasteurized beer
1 tablespoon sugar
1 teaspoon baking yeast
Plastic milk jug or large glass jar
15 1-quart plastic yogurt containers

Directions

1. Mix ingredients together in the milk jug or jar. If you're not sure whether the beer you have is unpasteurized, check the bottle label.
2. Let the mixture sit in a warm (70°F) place for a few days, until you see bubbles form.
3. While the mixture is brewing, make some of Carl's Seattle-style slug traps by cutting openings 1 inch high x 2 inches wide in the sides of the yogurt containers.
4. Pour the beery brew about ½ inch deep into the yogurt containers and replace the lids.
5. Bury the yogurt containers around your garden so that the openings in the sides are about ¼ inch above the soil line.

Yield: Enough brew to fill about 15 slug traps

Note: When setting the traps, make sure that the windows in the traps are just a little higher than ground level to keep ground beetles from falling in. Ground beetles eat slug eggs, so the more of them you have, the better. Empty, clean, and refill the traps every 3 days, Carl advises. "Slugs like fresh beer. They won't go in there if it smells like bacteria," he says.

A LOW-PROFILE SLUG TRAP

Here's an inconspicuous beer-baited slug trap that's perfect for high-visibility flower beds. Save some 1-liter soda bottles. Cut the bottles in half, and insert the top half of the bottle upside down into the bottom half. This will create a funnel effect. Pour ½ cup of beer into each funnel and sink the bottles partway into the soil. The slugs will crawl in and drown. To clean out the traps, remove the funnel part, and pour the contents of the traps on your compost pile. Then you can add fresh beer, put the funnels in place again, and put the traps back in the garden.

Slug-Dissolving Spray

Fry baby slugs alive when they're hiding in the crowns of daylilies and other perennials in the spring. For slugs that are too small to handpick or be attracted to traps, Marianne Binetti uses this recipe in her Washington State garden.

Ingredients and Supplies

1½ cups nonsudsing ammonia
1½ cups water
1-quart pump spray bottle

Directions

1. Pour the ammonia and water into the spray bottle.
2. Shake gently to mix.
3. Spray the mixture in areas where small slugs appear to be active.

Continued ➔

Note: "It fries the skin off the slugs, but it doesn't hurt the plants, and the ammonia breaks down into nitrogen," Marianne says. She keeps a spray bottle filled with this solution by the back door so that it's always ready to use when she discovers slimy slugs slinking around in her garden.

Flower Pot Death Traps for Slugs

Some people eat snails, but nothing eats slugs except other slugs. All slugs are cannibals, so you can trap them using fellow slugs as bait. Marianne Binetti, a garden columnist and television personality from Enumclaw, Washington, came up with an attractive but deadly way to deal with slugs that reside near her raised beds.

Ingredients and Supplies

Clay pots of various sizes

Directions

1. Put clay pots on the frame of your raised beds, upside down, with ½ inch of the lip extending out from the frame.
2. After a few days, check each of the pots for slugs.
3. Knock any slugs that you find out of the pots. Smash the slugs on the top of the bed frame, and rearrange the pots so that they cover the dead slugs. The dead slugs attract more slugs to the pots, so you can kill more slugs every few days. "I know it sounds horrible, but it works," Marianne says.

BURLAP BAG BOOBY TRAP

Slay slippery little milk slugs before they shred young lettuce or other spring seedlings. Seattle Tilth demonstration garden coordinator Carl Elliot lays down old burlap bags all around his lettuce bed.

In the morning, when the slugs have retreated under the bags to hide for the day, Carl crushes them with his feet. He leaves the dead slugs under the bags to lure more slugs.

Mealybug Death Drench

Melt mealybugs from the stems of orchids and sensitive tropical houseplants with this cheap and easy spray. Bob Thompson, an orchid hobbyist who lives near Daytona Beach, Florida, says this formula will control mealybugs on any plant, including citrus and poinsettias. The soap kills some of the mealybugs right away as it penetrates their protective coating, Bob says. Survivors are then suffocated by the thin coating of corn oil. "It's horribly effective," Bob reports. "Within days, every mealybug is gone."

Ingredients and Supplies

1 gallon water

Pressure sprayer

2 tablespoons corn oil

2 tablespoons dishwashing liquid

Directions

1. Place the water in a clean pressure sprayer.
2. Mix in oil and dishwashing liquid.
3. Apply thoroughly to plants infested with mealybugs. Make sure the mixture coats the insects well. The mixture will not harm sensitive orchid foliage, but to be effective, it must contact the insects directly.

Yield: 1 gallon of mealybug-killing drench

Note: Bob usually makes a gallon-size batch of drench for his greenhouse full of orchids. For smaller jobs, just make a quart of drench and use a pump spray bottle.

Recheck your plants about 2 weeks after treatment because some mealybug eggs may have survived. If you find only a few mealybugs, either repeat the treatment or follow up with an alcohol spray (see "Massacre Mealybugs with Rubbing Alcohol" below).

MASSACRE MEALYBUGS WITH RUBBING ALCOHOL

If you have only one plant infested with mealybugs, don't mess with a soap spray. Just spritz the mealybugs with rubbing alcohol. Bob Thompson keeps a small spray bottle filled with alcohol in his orchid greenhouse and uses it to neutralize any mealybugs he finds on isolated plants. Bob uses rubbing alcohol straight from the bottle (it's usually a mixture of 70 percent alcohol and 30 percent water).

Steam Treatment for Fire Ants

If you share your garden space with fire ants, you know how painful their stings can be. Gwen Snyder and Phil Strniste, owners of Bee Natural Farm in Fairhope, Alabama, keep fire ants at bay by steaming the mounds with hot water to kill the queen ants and disperse the colonies.

Ingredients and Supplies

1–2 gallons water

Large pot (such as a canner)

Cooking thermometer

Directions

1. Put the water into the pot. Be sure that you can carry the pot comfortably. If a large pot filled with water is too heavy, use smaller pots. (The last thing you want to do is burn yourself by spilling the hot water.)
2. On the stove, heat the water to between 160° and 170°F. Gwen and Phil find that this temperature is hot enough to kill fire ants and safer to handle than boiling water.
3. Quietly carry your pot or pots of water outdoors and set them near the fire ant mound.

4. Douse the mound quickly with 1 to 2 gallons of hot water. Your objective is to kill the queen, so don't disturb the colony before pouring on the water. The worker ants will quickly spirit the queen away when the mound is disturbed. The queen is most likely to be active on a warm day between 11:00 A.M. and 2:00 P.M.

Note: By the time you return to the ant colony on the second day, the surviving ants will have built a new home. To really be effective against large colonies, the treatment may need to be repeated for 3 consecutive days, Gwen and Phil say. If the colony disappears after 1 or 2 applications, look around to see if the ants have moved to a new spot. Continue to steam out any small colonies as soon as they appear, provided that they are far enough away from plants that the hot water will not injure the plants' roots.

FIRE ANT STICKY TRAPS

In their garden, Gwen Snyder and Phil Strniste find that hot water never gets rid of every last fire ant. They use a different method for keeping ants from chewing on okra flowers and pods, which fire ants are especially fond of. Phil paints the main stems of his okra plants with a sticky substance used to trap insects, such as Stickem or Tangle-Trap. The fire ants either get stuck or won't try to cross the sticky barrier, so they never reach the flowers and pods.

You can also use a band of sticky goo to protect citrus trees from fire ant feeding. Fire ants chew on the bark and growing tips of citrus trees and also feed on the fruit.

TRY A DUSTY FIRE ANT DETERRENT

Disturbing an active fire ant mound is certainly no picnic for you or your pets, and it's all too easy to do in an area infested with these pests. Although they're small—⅛- to ¼-inch long—fire ants inflict a painful sting, and they often attack by the hundreds when their territory is invaded.

Fire ants are pests in the garden, where they may damage eggplant, corn, okra, strawberries, and potatoes. They can also become household pests, entering through small cracks near the soil line and building nests inside walls, around plumbing, and under carpeting.

If you live in an area where fire ants are active, use a dusty barrier of diatomaceous earth (DE) to help keep these pests from moving into your garden or your home. DE is a natural material made from the fossilized remains of diatoms. When insects come in contact with DE, it damages and dries their waxy outer skeleton, and they die of dehydration.

To keep fire ants out of your house, caulk openings, especially near the soil level. Then apply a 2- to 3-inch band of DE around the foundation. Use a similar DE band around your garden to exclude fire ants from your crops. Wear a dust mask and goggles when applying DE to avoid inhaling the dust or getting it in your eyes.

Chigger-Chasing Sulfur

If you live in the Southeast, you probably know the unpleasant aftereffects of an encounter with chiggers. Take heart! You can conquer the chiggers lurking in your lawn with two well-timed applications of soil sulfur, a concentrated sulfur product available at some garden centers that is used to lower soil pH. Trisha Shirey, grounds manager at Lake Austin Spa Resort in Austin, Texas, says this remedy is especially effective in soft swaths of Bermuda grass.

Ingredients and Supplies

5 pounds powdered soil sulfur
Drop or broadcast spreader
Rubber gloves
Dust mask
Oscillating sprinkler

Directions

1. Early in the morning when the grass is wet with dew, use the drop or broadcast spreader to apply the sulfur, taking care to apply it as evenly as possible. Sulfur is a natural chemical dust, so wear rubber gloves and a dust mask to protect your hands and lungs while you work.

2. Immediately water the area for about 20 minutes using an oscillating sprinkler. Be sure that the sulfur is completely washed down into the grass.

Yield: Enough sulfur to treat 100 square feet of lawn

Note: For best results, Trisha suggests following this procedure twice each summer—once in late spring and again in late summer. Trisha thinks that the sulfur treatment can also help control fleas in the lawn.

SULFUR SIDE EFFECTS

Sulfur not only chases chiggers away but it also tends to lower soil pH (makes the soil more acidic). So if you're applying sulfur on soils that tend to be alkaline, you're probably doing yourself a double favor. But if your soil is naturally acidic, check the pH in the fall if you used soil sulfur during the summer. If the pH has fallen below 5.3, you'll need to apply lime to raise the pH. Ask your local Cooperative Extension Service for recommendations on how much lime to apply.

Rub Out Pests with Rubbing Alcohol

Houseplants bothered by pests? Rub them out with rubbing alcohol. Gardener Dominique Inge of Granbury, Texas, finds this recipe effective against mealybugs, whiteflies, red spider mites, aphids, fungus gnats, and scale. She cautions that it may cause leaf burn on some plants and doesn't recommend it for African violets.

10 Fast Ways to Control Pests

Vicki Mattern

Did insect pests get the best of you and your garden last year? Were you witness to overnight attacks on your veggie crop? Are you a bit worried that this year might bring a repeat performance? Never fear! Here are 10 timely, timesaving tips to help you take charge of your garden's bad bugs *now*:

1. **Mix your signals.** A confusing mix of sights and scents can help deter certain insect pests. So try to increase biodiversity and avoid monoculture by mixing plants from different families. Instead of planting long rows of a single crop, plant onions alongside broccoli, tomatoes with basil and chives, and peas with carrots. Better yet, interplant edibles with ornamentals. Add a few hot pepper plants to your flowerbeds, or edge your vegetable beds with low-growing annual flowers, such as alyssum and dwarf marigolds.

2. **Attract an airborne defense squad.** One of the best ways to short-circuit an onslaught of pests is to attract an airborne cavalry charge of beneficial insects. Many beneficials—including the small wasps that prey on pest caterpillars—will gratefully take advantage of the flat-topped floral landing platforms offered by members of the umbel family, which includes dill, Queen-Anne's-lace, parsley, and carrots. (You have to allow the parsley and carrot plants to overwinter and grow into their second year to get those umbrella-shaped flowers that beneficials find so attractive.) Other plants beloved by beneficials include sweet alyssum, all kinds of mints, and chamomile.

3. **Negate nematodes.** Marigolds can greatly reduce the damage caused by root-ravaging nematodes—those tiny soil-dwelling wormlike pests—but only if you use them correctly. For the best effect, grow a thick stand of marigolds as a cover crop for a season, then turn them under the soil. The next year, plant whatever you like in that area—nematodes won't be around to cause trouble underground.

4. **Grow your own decoy (#1).** Try allowing a single weed to grow as a decoy among your cultivated crops. Decoy crops may attract pests and help to keep the bad guys away from your other crops. Striped blister beetles, for instance, seem to prefer redroot pigweed to tomato plants growing nearby. To keep the insects from moving to your tomatoes, check the pigweed each morning and shake off any beetles into a bucket of soapy water.

5. **Grow your own decoy (#2).** You can trap flea beetles in a similar manner using arugula, the spicy salad green. Pesky flea beetles—a voracious pest of eggplants, brassicas, and potatoes—will flock to the arugula first. Use a handheld vacuum to suck the beetles off the decoy plants before they can make their way to your main crops. You may have to repeat the vacuum cleaner escapade a few times each season to keep ahead of the invading flea beetle army.

6. **Grow your own decoy (#3).** Knowing that aphids are attracted to all things yellow, the staff of Ecology Action in Willits, California, have learned to plant yellow nasturtiums at the base of tomato plants to lure aphids away from the tomatoes. Monitor the nasturtiums closely, they urge. After the flowers have drawn in the aphids—and before the aphids reproduce—pull out the decoy plants and destroy their load of insects.

7. **Set up traps!** Earwigs, sow bugs, pill bugs, slugs, and snails all have one thing in common: They like to hide out in damp, shady places during the heat of the day. To take advantage of this trait, lure them with attractive "trap nests"—boards, pieces of paper, seashells, broken crockery, etc. Get out early every morning to check each lure, then dump the trapped critters into a bucket of soapy water.

8. **Pull back the mulch.** Organic mulches such as straw and leaves prevent weeds, maintain soil moisture, and improve soil quality. Unfortunately, under certain conditions they also can provide a home for insects that feed on tender young plants, such as slugs, sow bugs, and pill bugs. If these pests typically pose a problem in your garden, pull your mulch at least 2 inches away from the stems and stalks of transplants and young seedlings.

9. **Pull up those covers.** Sometimes the best way to head off insect trouble is to stretch some row covers over your crops. Besides keeping out pests, such as cucumber beetles, squash bugs, and cabbage maggots, row covers speed crop growth by trapping a blanket of warm air around new seedlings and established plants.

10. **Take out the apples and the trash . . .** Cleaning up garden debris may not be the flashiest method of controlling pests, but it is certainly one of the most effective and, by far, the easiest. By allowing insect larvae to overwinter in your garden and orchard, you are locking yourself into a cycle of repeated infestation. To break the cycle, promptly clean up all faded flowers, spent crops, and fallen fruit at the end of the season.

Ingredients and Supplies

½–1 cup rubbing alcohol
1 quart water
Pump spray bottle

Directions

1. Mix ingredients in a pump spray bottle.
2. Test spray on a leaf to check for burning.
3. Wait 1 day and check for damage before treating the entire plant.
4. Treat at 3-day intervals for 10 days or as needed. Don't use this in the heat of the day.

Yield: 4½–5 cups of alcohol spray

WASH AND VACUUM PESTS AWAY

Ordinary water is a great weapon for dispatching houseplant pests. If your houseplants are infested with spider mites or aphids, try putting the plants in your kitchen sink and running a strong stream or spray of cool water over the foliage and stems. The force of the water can literally wash whiteflies, mites, and aphids right off the plants. Check the plants a few days later. If you find pesky pests that survived the treatment, wash the plants again. (Note that African violets dislike having their foliage washed, so don't try this technique on your violets.)

For plants that you can't wash, try vacuuming instead! Get out your handheld vacuum cleaner. With one hand, move the vacuum lightly over the plants, and with the other hand, support or hold the foliage so that the suction of the vacuum won't tear the leaves. Keep in mind that the insects you vacuum up may be only stunned, not killed. When you're finished pest-vacuuming, move away from your plants before you open the vacuum. Dump the pests into soapy water to kill them. This treatment works well for whiteflies, but may not be strong enough to suck off aphids or all spider mites.

Tomato Stake Whitefly Trap

Trick whiteflies with the color yellow. Whiteflies are attracted to yellow surfaces, and you can buy commercially produced traps that have sticky yellow surfaces where whiteflies land and get fatally stuck. In Brooklyn, Ohio, tomato lover Katherine Jarmusik came up with a nifty way to recycle some household items into a sticky whitefly trap at a cost that is much lower than the price of commercial traps.

Ingredients and Supplies

4 (6-foot-long) tomato stakes
4 (48-ounce) juice cans, each with 1 end removed
Yellow paint
Paintbrush
12 yellow or clear plastic bags (like the ones used to cover newspapers on rainy days)
Petroleum jelly

Directions

1. Use the stakes to support growing tomatoes. Or, if you're already using another type of support for your tomatoes, pound in the stakes alongside the plants. Four stakes set every 2 feet will protect a row of 10 tomatoes.
2. Paint the juice cans yellow.
3. Place the painted cans over the tops of the tomato stakes.
4. Cover each can with a yellow or clear plastic bag.
5. Smear petroleum jelly on the outside of the bags.

Yield: 4 super-sticky whitefly traps

DEALING WITH DEAD WHITEFLIES

Whiteflies are so attracted to her yellow traps that the whole bag is soon covered, Katherine Jarmusik says. When the whiteflies get too thick on the bags, she removes the old bags, throws them away, and replaces them with new ones that are coated with fresh petroleum jelly.

Katherine finds that 4 cans, with 2 or 3 bag replacements per can, are enough to protect her 20 x 30-foot garden plot from whitefly damage. Yellow is the key to success with these traps, Katherine points out. "If you have enough yellow plastic bags, you can skip the step of painting the cans."

Vinegar Foils Fungus Gnats

Lure fungus gnats and fruit flies to a watery death with a simple cider vinegar trap. Christine Haugen, director of Green Horizons International, who specializes in earth-safe pest control, uses this formula when fungus gnats or fruit flies invade her Virginia home. "The gnats will find the jar within a few minutes and land on the rim to investigate," Christine says. "Then they will continue on in and drown."

Ingredients and Supplies

1 small wide-mouth jar (a baby food or bouillon jar works well)
1 tablespoon cider vinegar

Directions

1. Fill the jar about ⅞ full with water.
2. Add the vinegar.
3. Place the jar on a kitchen counter or table, especially near ripening fruit. You can also place the traps near houseplants if they're infested with fungus gnats. Leave the trap undisturbed.

Continued →

Yield: About ⅔ cup of fungus gnat attractant

Note: In most situations, all the fungus gnats and fruit flies in your house will die in the trap within a few days. If you have a severe problem, you may need to replace the mixture in the jar after a week or so.

FIGHTING FUNGUS GNAT LARVAE

Fungus gnats look like tiny fruit flies with beige wings. The gnats may lay eggs in the soil of houseplants, and their larvae may suck juices from the roots of the plants. Since the cider vinegar traps attract only adult fungus gnats, Christine Haugen suggests using neem to control the larvae in the soil. Neem is an organic pest control product extracted from the neem tree; it's available at garden centers and from mail-order garden suppliers.

Confuse Cuke Beetles with Rattails

Confuse cucumber beetles and other garden pests by planting rattail radishes in and around your vegetables. After Master Gardener Carol Kelly of Saltsburg, Pennsylvania, heard other gardeners talking about interplanting radishes with pest-plagued crops, she decided to try rattail radishes, a special variety of radishes that have edible pods. She especially recommends planting this tasty deterrent around your summer squash plants to repel cucumber beetles.

Carol thinks that regular radishes will discourage cucumber beetles, too, but the rattail radish plants grow bigger—often 18 inches tall—and she likes the flavor of the edible pods, which appear after the flowers. "I pick them when they're still young and tender and chop them into salads," Carol says. Rattail radishes develop a thick taproot, but it's not edible like other kinds of radishes.

Ingredients and Supplies

1 packet summer squash seeds

1 packet rattail radish seeds

Directions

1. After danger of frost has passed, plant squash seeds or transplants directly in the garden.
2. Sow a few rattail radish seeds in between the rows or around the hills of squash and at the ends of the rows. Rattail radish seeds are available in seed catalogs—check the listings for oriental vegetables.

Onion Rings for Cabbage Loopers

Confuse cabbage loopers and cabbageworms by surrounding your broccoli, cabbage, and cauliflower plants with onions. In both spring and fall, Charlotte, North Carolina, gardener Jeff Davis sees very few loopers when he uses this easy companion planting method.

Ingredients and Supplies

20 assorted cabbage, cauliflower, broccoli, kohlrabi, or brussels sprout seedlings

100 onion sets

Directions

1. In the spring, set out the seedlings in the normal manner, spacing them at least 18 inches apart.
2. As you settle in each plant, surround it with a ring of onion sets, spacing them 4 inches apart. The idea, Jeff says, is to encircle the cabbage family plants so that they're hidden by a screen of onions.

Note: Jeff inspects his plants often in search of cabbage loopers, but rarely finds one of the leaf-eating visitors. On 20 cabbage plants surrounded by onions, he may find 3 loopers at the peak of their season.

Some of the onions eventually grow into bulbs, but Jeff harvests most of them for use as green onions.

Beetle-Busting Potato Planting

Outsmart Colorado potato beetles before they stage a feast in your potato patch. Cynthia Connolly, an organic market gardener in Monticello, Florida, uses a companion planting plan to confound the beetles. Her not-so-secret weapons are garlic and onions. "The year we first tried this, Colorado potato beetles devastated our other potatoes, but the ones grown with the garlic had hardly any damage at all," Cynthia explains. Potato beetle adults looking for host plants upon which to lay eggs apparently are confused by the barrier of onions and garlic that guards the spuds.

Ingredients and Supplies

30 garlic cloves or plants

40 onion plants or sets

Seed potatoes for a 20-foot-long row (about 5 pounds)

Directions

1. In the fall, dig or till a garden bed or row in an area of your garden where potatoes have not been grown for 2 years.
2. Plant sprouting garlic cloves (or set out garlic plants) in a line down the outside of one side of the row or bed.
3. In early spring, plant seed potatoes down the middle of the prepared row or bed.
4. Plant onion plants or sets down the side of the row or bed opposite from the garlic, so that the potatoes are surrounded on all sides with garlic and onions.

Gummy Grasshopper Flour Formula

Stop grasshoppers from eating your plants by making them eat all-purpose flour. When you use this simple flour dust, grasshoppers, blister beetles, and other chewing insects will end up with their mouthparts so gummed up that they can't eat another thing, reports Trisha Shirey, grounds manager at Lake Austin Spa Resort in Austin, Texas.

Ingredients and Supplies

3 cups plain all-purpose flour

Garden duster or salt shaker

Ice pick or carving fork

Garden hose with spray nozzle

Directions

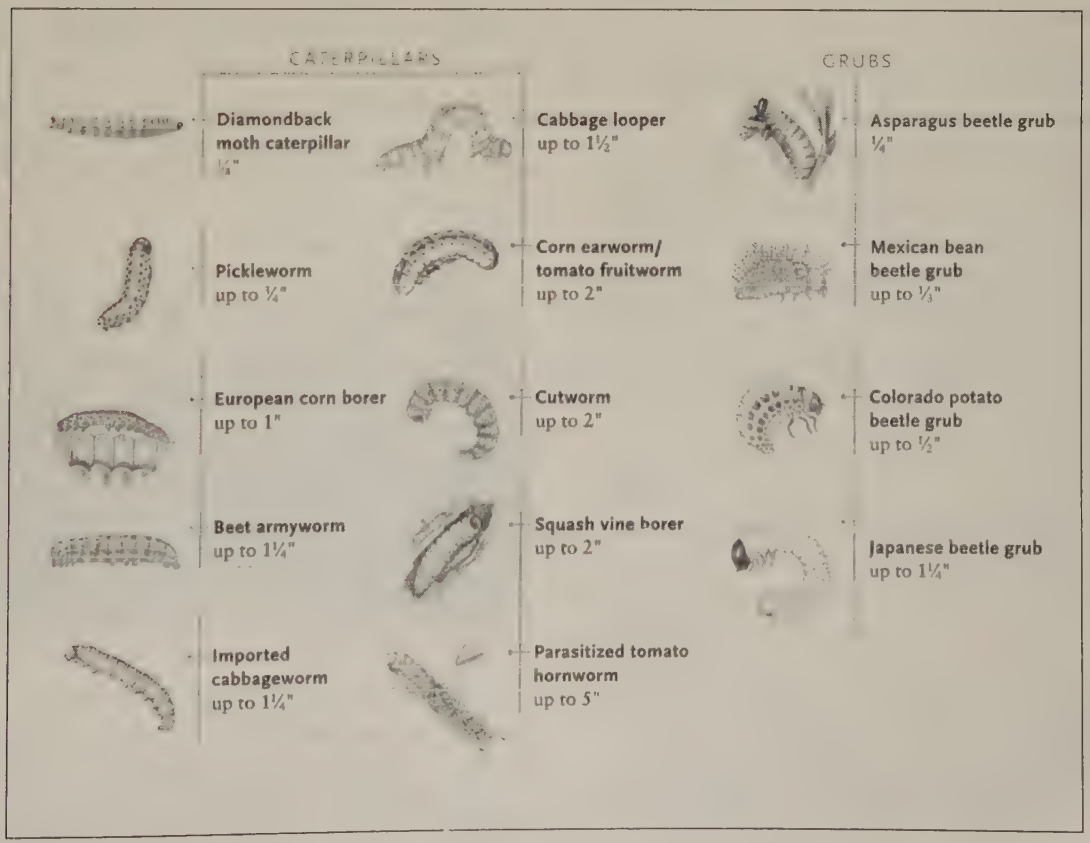
1. Put the flour in the garden duster. (If you're treating only a small area, use less flour and put the flour in a salt shaker.)
2. Go out in your garden and jiggle the plants upon which grasshoppers or blister beetles are feeding (this gets the insects moving).
3. Dust the insects and the leaves with flour.
4. After 2 days, rinse off the flour using a fine spray from a hose. On plants with hairy leaves, such as tomatoes, you may need to rinse twice to clean off the flour.

Note: When the grasshoppers eat dusted leaves, they ingest so much flour that they become sick and stop eating, Trisha says. Since the success of the method hinges on getting plenty of flour on the leaves that the bugs are eating, it's best to apply the dust in the morning, while the plants are damp with dew.

As long as you rinse off the flour after 2 days, you won't harm your plants. But don't use self-rising flour, because the salts in that type of flour may injure plant leaves and aren't good for your soil.

PAPER BAG DUSTER

If you don't have a commercial garden duster, save yourself the investment by improvising a duster using a simple brown paper lunch bag. With an ice pick or carving fork, punch about a dozen small holes in the bottom and lower sides of the bag. Put flour in the bag. Then, when you want to apply the dust, hold the bag closed with one hand and tap the bottom of the bag with your



Continued ➔

other hand to release a cloud of floury dust. Empty powder containers, grated cheese jars, or discarded spice jars with shaker lids are other good prospects for recycling into a duster. Anything with a shaker top works well for this type of non-measured application.

Insect Glossary

Abdomen The last section of an insect's body, following the head and thorax. Digestive and reproductive organs are found in the abdomen.

Antenna Paired, segmented structures, also called feelers; one on each side of the head. Aids sensory perception. Plural is *antennae*.

Beak Long, stylus-like mouthpart used by sucking insects to pierce the surface of a plant or animal; hollow and jointed. One or more tiny needles in the beak pierce the tissue.

Brood All the insects that hatch from eggs laid by a given mother, or those that hatch and mature at the same time. Commonly used to refer to bees.

Caterpillar Larval stage of a butterfly or moth. Segmented or wormlike, with a distinct head, 12 simple eyes, a pair of very short antennae, and usually six well-developed legs, as well as two to five pairs of prolegs.

Chitin A hornlike substance that forms a layer of the exoskeleton.

Chrysalis The tubular, hard pupal shell of a butterfly.

Class The largest subgroup of a phylum. Insects belong to the class Insecta or Hexapoda (meaning "six-legged").

Cocoon The silken pupal case of a butterfly or moth.

Compound eye The eye of an insect, composed of many separate hexagonal lenses fitted closely together; sensitive to movement and color. Larvae lack compound eyes.

Crawler The first active instar of a scale.

Cuticle The outer layer of the exoskeleton.

Dormant Inactive; in suspended animation; hibernating. Dormancy occurs in winter.

Elytra The hard, opaque wing covers of which meet in a straight line down the insect's back and cover most of the thorax and abdomen, giving an armored appearance.

Exoskeleton The hard outer covering or skeleton that protects an insect's body like armor. Forms a jointed frame.

Family The largest subdivision of an order. Each family contains a group of related genera (see Genus). Family names end in "-idae."

Frass The sawdust-like excrement of borers such as the peachtree borer and the squash vine borer.

Genus The largest subdivision of a family. Each genus is made up of a small group of closely related members. Plural is *genera*.

Gregarious Living in groups, as in ants, aphids, and honeybees.

Grub The larva of a beetle. Grubs are plump, flat, or wormlike, with well-developed heads and three pairs of legs. They pupate in the soil or other protected sites.

Hibernation A winter period of suspended animation passed by many insects that live more than one season. Usually spent in soil or garden debris.

Honeydew A sweet substance secreted by aphids, which is relished by ants. Also produced by mealybugs, scales, and whiteflies.

Host plant The plant on which an insect feeds, lives, or lays eggs.

Instar The form of an insect between each molt. Most insects pass through three to six instars.

Larva Immature form of an insect that is more or less wormlike; may be legged or legless; may be smooth or covered with spines or tufts of hair. They have chewing mouthparts. Plural is *larvae*.

Maggot The larva of a fly, usually a small, white, legless worm without an obvious head. Mouthparts are hooked. Maggots tend to feed inside the host plant or animal.

Mandibles The strong chewing jaws of arthropods.

Maxillae Second pair of jaws just behind the mandibles.

Metamorphosis A form change during which an insect molts and passes through nymph to adult stages (incomplete metamorphosis) or through larval to pupal and adult stages (complete metamorphosis).

Molt A shedding of the exoskeleton so that an insect can grow. The old skin splits after a new one has formed beneath it.

Nymph An immature adult with undeveloped wings and, in some cases, different markings from the adult.

Ocellus The simple, single-lensed eye of an insect. It perceives light but produces no image. Insects usually have them as well as compound eyes. Found at the base of the antennae or on top of the head. Larvae rely on them entirely. Plural is *ocelli*.

Order The largest subgroup of a class. Insects are divided into 26 orders. Each order contains a large group of insects that share similar wing structures.

Oviparous Egg-laying.

Ovipositor The egg-laying organ in female insects.

Parasite An insect that lives and feeds in or on another insect or animal for at least part of its life cycle.

Pheromone A chemical substance, such as a sexual attractant, secreted by an insect to create a response in others of its species.

Phylum A major division of the animal kingdom. Insects belong to the phylum Arthropoda (meaning "joint-legged").

Predator An insect that feeds on another live insect or animal.

Proboscis Long, retractable sucking tube through which nectar is syphoned by insects such as butterflies and moths.

Proleg A plump, fleshy, false leg that enables larvae to move more easily. Caterpillars may have up to five pairs, which are sometimes hooked to enable them to hang from a host plant.

Pubescent Downy; covered with short, fine hairs.

Pupa An inactive stage between larva and adult in which adult features develop. The pupa may be encased in a chrysalis or cocoon, or it may roll itself in a leaf. Plural is *pupae*.

Pupate To turn into a pupa.

Scavenger An insect that feeds on dead plants, dead animals, or decaying matter.

Sessile Incapable of movement; immobile. Some female scales are sessile.

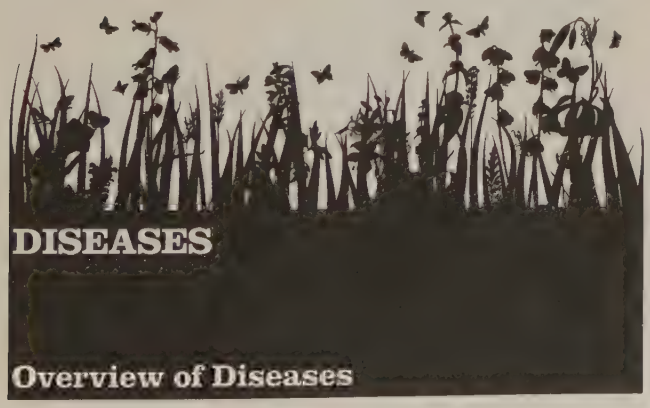
Species The fundamental unit in classification. The species refers to a single insect that may be distinguished from others in its genus by a particular feature or habit. Plural is *species*.

Spiracle One of many tiny holes in the thorax and abdomen of an insect that serve as breathing pores.

Thorax The center section of an insect's body, between the head and the abdomen. Wings and legs are attached to the thorax.

Vector A disease carrier.

Viviparous Bearing live young. Aphids can be viviparous.



Jill Jesiolowski Cebenko and Deborah L. Martin

Plant diseases can be hard to diagnose compared to insect problems. After all, potato beetles are quite visible, but it takes a microscope to see a virus or most fungi and bacteria. Diagnosing a disease is also difficult because symptoms can look like those that excessive cold or heat, sun scald, high salt levels, nutrient deficiencies, waterlogged soils, low light levels, and other problems can cause.

If you maintain well-drained fertile soil, enriched with compost, and take sensible precautions, such as cleaning up crop debris after harvest, you won't see many diseases in the garden. If, however, a disease problem recurs year after year or is especially damaging, you would be wise to learn what it is, how it spreads, and how to manage it and prevent it in the future.

Bacteria

Bacteria are microscopic, single-celled organisms. Each bacteria cell reproduces by dividing in two. The bacteria that attack plants produce toxic compounds that kill the plant cells; the bacteria then use the contents of the plant cells for their own growth. Plants react to such attacks by triggering the death of cells around the bacterial infection, which isolates the bacteria colony from the rest of the plant and causes the characteristic spots, or shothole appearance, in leaves as the dead tissue drops out.

Bacteria enter plants through openings such as pores and wounds. Some cause wilting, as the multiplying bacteria kill the cells in the vascular system or plug it with masses of bacteria. Others cause spots, rots, and blights, which are all symptoms of dying plant tissue. Some bacteria cause plant tissue to grow abnormally into galls.

Fungi

Fungi cause the majority of plant diseases. As a group, these microscopic organisms are distinguished by their lack of chlorophyll, which means that they can't make food for themselves and so must rely on getting their nutrients from other organisms or organic matter. Some fungi, called *saprophytes*, live only on dead organic matter. They break down organic material in compost piles and soils into forms that other organisms can use. Most pathogenic (disease-causing) fungi parasitize living plant tissue, but some can live off of both living and dead plant material. Many live all summer in plants, then they overwinter on dead crop debris.

Fungi have cells made up of branching filaments, or minute tubes, called *hyphae*. A group of hyphae form a *mycelium*, which typically looks like a velvety spot or coating on a leaf. Some fungi reproduce asexually from sections of hyphae called *sclerotia*, whereas others make reproductive units, called *spores*. Sclerotia are generally quite easy to see, whereas spores are usually microscopic.

Most fungi can make different types of spores to guarantee their survival in almost any situation. In general, asexual spores are produced in the best growing conditions. They are released from a special structure, generally called a "fruiting body." They're carried by wind, rain, animals, and sometimes people to new sites, where they germinate if temperature and humidity

Continued →

are right. Furthermore, pathogenic fungi that spend most of their life cycle on roots and debris underground commonly produce swimming spores, or zoospores. Fungi that attack plant parts above ground may also produce swimming spores that navigate through dew and rain on the leaves.

Spores that can remain dormant until they encounter good germinating conditions and an appropriate host are called *resting spores*. Fungi typically produce them in fall in preparation for winter. Some dormant spores can remain viable, or capable of germination, for years.

When spores germinate, they send out a tube, or *hypha*. This usually enters the plant through a wound or natural opening. Some pathogenic fungi are also capable of forcing their way into plant cells by exuding enzymes that kill the cells or by using a strong hypha tip that can bore into plant tissue.

Fungi cause wilting when mycelium plugs the plant's vascular system or destroys the cell walls. They also cause rots and blights as they release toxins that break down cells in seeds, roots, and fruits. Infected plants can appear *chlorotic* (yellowed) or have other discolorations caused as the plant cells die and as photosynthesis and other metabolic activity is restricted. Some fungi cause *galls* and *smuts*, which are abnormal growths of plant tissue.

Nematodes

Nematodes are actually a group of unsegmented roundworms. They range in size from microscopically small to several inches long. Some species break down organic matter, some attack insects, and others attack plants. The plant-feeding species are usually discussed with plant diseases because their mode of action and ways to control them are similar. Like fungi, some species of nematodes have a dormant state that can remain in the soil for many years.

The mouthparts of nematodes pierce plant tissue. Some species excrete a digestive juice that rots cells before they feed. Others exude substances that stimulate nearby plant cells to enlarge or multiply abnormally. They also carry many viral diseases. But even when they don't carry disease, the small holes they make allow other diseases to enter the plant.

Although they can move, nematodes are so tiny that they rarely travel more than a foot (30 cm) through the soil. They're usually introduced to a piece of land by infected planting stock, infested soil, or running water.

Viruses

Viruses are minute parasitic bits of genetic material (DNA or RNA) with a protein casing. Their genetic material causes host cells to make more viruses. Viruses can multiply only in a living host. Some viruses can remain inactive but viable for as long as 50 years in dead plant material.

Many viruses are carried by insects, which are then called *vectors*. Seeds may carry viruses, and infected propagating stock is certain to produce infected plants. Viruses can also be spread from one plant to the next on knives, equipment, and tools.

Three symptoms of viral infection are yellowing or other discoloration, stunting, and malformations. Mosaic patterns, ring spots, and a uniform pale color are all symptoms of infection. Stunting can affect a whole plant or one part, such as a leaf, branch, ear, or other part. Malformations include leaf rolls, puckering, and "shoestring" leaves (extremely narrow, twisted leaves).

The Spread of Disease

Plant pathogens spread in various ways. Spores and bacteria may be blown on the wind or carried on splashes of water. Many pathogens can be moved from plant to plant mechanically, meaning that animals, tools, equipment, and even gardeners that have come into contact with infected plant material can spread the pathogens. Insects can also spread some diseases by carrying the pathogens in their saliva from one plant to the next. As they feed on the sap, they release the pathogens into the new host. For any disease, knowing the life cycle of the pathogen and the way it spreads can help you avoid bringing it into your garden and spreading it further.

DISEASE RESISTANCE

Plants are immune to many diseases because the pathogen simply can't attack a particular host. For example, potatoes are immune to attack from corn smut fungi and corn is immune to late blight. In contrast, resistance means that the plant may have some degree of susceptibility to the pathogen, but it's able to fight against it. Many varieties of garden vegetables have been bred for resistance to certain common diseases.

Resistance can be *genetic*, meaning it's an inherited characteristic of the plant, or *induced*, meaning that the plant's immune system has been activated to fight off infection. Plants that have been bred for resistance may have physical characteristics, such as a thicker leaf cuticle (the exterior surface of the leaf) or woodier stems, which repel the action of germinating spores.

Plants can also be selected for their strong immune response that helps them tolerate diseases well enough to produce a useful crop. Some plants can quickly mobilize a cell response that neutralizes invading pathogens. This response causes the cells around an infected area to die. The layer of dead cells isolates the infection from the rest of the plant and causes the corky spots or holes in leaves that are characteristic symptoms of some diseases. Other plant responses to infection are uncannily like our own immune system because exposure to a pathogen activates genes that cause the plant to become resistant to later attacks.

The environmental conditions a particular plant is growing in also help determine whether or not it can resist infection. For example, a variety with cuticles thick enough to repel

germinating spores when it's growing in good conditions might still be infected in low-light conditions when the leaf growth is weaker and the cuticle thinner. Plant nutrition, watering, light levels, and other conditions also contribute to disease resistance.

PREVENTION AND CONTROL

Before any disease can occur, the three elements of the "disease triangle" must be present: a susceptible plant, the disease-causing agent (pathogen), and favorable environmental conditions for growth of the pathogen. A disease can't develop if even one of these elements is absent. Most prevention and control measures for managing plant diseases are based on removing one or more of these elements.

For example, susceptible plants can be removed from the equation by planting resistant or immune crops. Pathogens can be removed from the equation by removing infected plants from the garden. Although gardeners can't control the weather, they can make environmental conditions unfavorable for pathogens by avoiding overhead watering, pruning to promote good air circulation, and taking other precautions.

Prevention

Healthy plants. Start with certified disease-free seeds, tubers, and plants where possible, and give them the best care. Of course, fertile soil, fed with compost and enriched with high levels of organic matter, is the key to growing healthy plants that resist infection. It's important to correct any problems with soil drainage. Reduce the length of time plant leaves are wet by installing drip irrigation, watering only at the base of the plant, or using sprinklers only in the morning so that leaves have a chance to dry before evening. Pruning and spacing plants to increase air circulation between plants also allows leaves to dry faster and thwarts the spread of many fungi. Plant the right plant in the right spot—for instance, a shade-loving plant won't do well in full sun and in such a weakened state will be more susceptible to attack.

Resistant varieties. Whenever possible, choose disease resistant or tolerant varieties when buying seeds, tubers, transplants, and nursery stock. Read descriptions in seed catalogs to find varieties that have disease-fighting characteristics. Tomato varieties are commonly labeled with V, F, or N (sometimes all three): The "V" means verticillium-resistant, "F" means fusarium wilt-resistant, and "N" means root-knot nematode-resistant. For other types of plants, look for descriptions such as "resistant to powdery mildew," "tolerant of anthracnose," or "scab-resistant."

Preserve natural enemies. Finished compost is a rich source of beneficial soil fungi, bacteria, and other organisms that help protect plants from disease. These naturally occurring microorganisms are invisible, but they're vital in protecting plants. Some suppress pathogens in the soil by producing compounds that inhibit their growth. Others actively attack pathogens and some colonize plant roots, which keeps pathogens out. Airborne fungi, yeasts, and other microorganisms also live on the surface of leaves and protect them from attack. Because sprays aimed at controlling pathogens can also kill these beneficial microorganisms, it may be good to avoid using such sprays unless they're absolutely necessary.

Cultural Controls

Remove alternate hosts. For example, some rusts can't complete a life cycle without a specific, alternate host plant, such as cedar for cedar-apple rust or juniper for pear-trellis rust. If there are a few of the alternate host plants in the area, removing them can reduce or eliminate the disease locally. If there are many alternate hosts in the area, then it may be hard to have an effect.

Crop rotation. A way to reduce the spread of soilborne pathogens is to avoid planting susceptible plants in infected soil until infective spores die off. Because some pathogens can live in the soil for a couple of years, it's necessary to grow nonsusceptible plants in those soils during that time. Crop rotation is also a preventive measure to ensure that pathogens that might be present at low levels don't have a chance to build up to damaging levels.

With that in mind, though, crop rotation in a home garden is less effective than in a larger area because it's hard to rotate the susceptible crop a great distance from the initial site of infection. It helps to use permanent raised beds, especially if coupled with careful sanitation measures. Where the whole garden is plowed or tilled at one time, infected soil is spread around.

To rotate crops effectively, it's important to know which plant belongs in each family so that you don't mistakenly plant related crops one after the other. For example, tomatoes, potatoes, eggplant, and peppers are all in the same family (Solanaceae), and cabbage, cauliflower, broccoli, mustard, radishes, turnips, Chinese cabbages, and brussels sprouts are all related (Cruciferae). When planting herbs and annual flowers in the garden, they should also be considered in the crop rotation because many belong to the same families as garden vegetables. For example, sweet alyssum is a member of the cabbage family (Cruciferae), and dill and coriander are in the same family as carrots and celery (Umbelliferae).

Physical Controls

Sanitation. The sources of disease infection (*inoculum*) around the garden can be reduced or eliminated by cleaning up crop debris and pulling out infected plants. Where allowing infected plants to remain could jeopardize the whole crop, it's advisable to pull the whole plant, including roots and sometimes the surrounding soil, and remove it from the garden. Whether or not infected plant material can be composted depends on what

Continued →

the organism is and how hot the composting process is likely to be. In some cases it's advisable to burn, bury deeply, or discard infected plants in the garbage rather than compost them.

Cleaning tools and implements, as well as shoes and hands, is an especially important sanitation measure when moving from infected plants or soils to uninfected areas. Also, avoid moving from plant to plant when humidity is high enough to leave a film of moisture on leaves, as diseases can be spread quickly this way.

Removing weeds in the garden and from nearby areas can help manage some diseases if the weeds are likely to harbor diseases affecting crop plants. This is most effective if there are very few such disease host plants in the area. Some plant diseases are spread so widely on the wind that host plant removal doesn't contribute to control.

Barriers. If a disease is spread by sucking insects, such as aphids or leafhoppers, screening out the insect carrier can exclude the disease. Sprays of kaolin clay can be used to coat leaves and fruit with a fine barrier of clay, which foils the leafhoppers and other insects and prevents some pathogenic fungi from attacking.

Hot-water treatments. Hot-water treatments can be used to kill some pathogens carried in certain types of seeds. Some commercial seeds are already heat treated; gardeners can also use hot water to treat their own seeds. Follow recommendations given under the disease entries for exact temperatures and timing.

Solarization. Solarization involves covering soil with clear plastic during the summer months to heat it 6 to 8 inches deep to temperatures that kill pathogens. Solarization has been shown to keep soil-borne pathogens—such as verticillium, fusarium, southern blight, and nematodes—in check for 2 to 3 years. First, remove all vegetation, rake the soil smooth, soak it well with water, then cover with clear plastic stretched tight over the surface. A clear plastic tarp or 4-mil-thick plastic sheeting can be used. Bury the edges of the plastic 6 inches deep to achieve a good seal. Leave in place for 6 to 14 weeks in the hottest part of the summer. This works best in the warmest regions. In northern regions, use two layers of plastic with a thin air space between them to increase the heating effect, and leave the soil covered for the maximum length of time.

Biological Controls

Fermented compost tea. The many beneficial microorganisms found in compost can be used effectively as a disease treatment by steeping compost in water to make a tea. It has been found that the tea is more effective as a disease control when it's allowed to ferment. Use finished compost and steep 1 part compost to 5 to 8 parts water for 3 to 7 days (2-week fermentations may be more effective on some diseases). Strain the liquid and filter it through a fine screen before putting it in the sprayer. Apply the tea to the lower part of the plant stem and around the roots for soil-borne diseases or onto leaves for powdery mildews.

Commercial products. Various naturally occurring fungi (e.g., *Ampelomyces quisqualis*) and bacteria (e.g., *Bacillus subtilis, Pseudomonas* spp.) are becoming increasingly available to buy. Depending on the product, they're applied to leaves, roots, or branches to suppress plant diseases. However, these products are probably more useful for commercial growers than home gardeners, who may find them too expensive for use on the few plants that might benefit.

Fungicides

As with any type of treatment, it's important to make sure that the problem is correctly identified and that treatment is really necessary before using sprays or dusts. Unfortunately, these must be applied before pathogens infect plants to provide a protective barrier—once plants have been infected, they can't be cured by such treatments (though healthy plants can fight some types of infections). Most sprays and dusts can also harm beneficial microorganisms that help protect plants from pathogens. Fermented compost tea sprays are an exception because they actually add beneficial microorganisms.

Water. In the case of powdery mildew, the presence of water on the leaf stops spores from germinating. Spraying leaves thoroughly on both sides with plain water in midday several times a week can provide satisfactory control. This isn't a useful method where plants are also susceptible to other diseases that would develop in wet conditions.

Milk. Fresh milk sprays made from 1 part milk and 9 parts water and sprayed twice a week have been shown to suppress powdery mildew of cucumber and zucchini. It's thought that the milk may work by preventing the fungus from invading, or it may boost the plant's immune system by providing nutrients.

Oils. Narrow-range oils are mainly insecticidal, but they can be used to control plant diseases such as powdery mildew. Mix according to product instructions for use on plants during the growing season.

Botanical extracts. Garlic sprays and essential oils from some plants have some disease-suppressing properties. These are becoming increasingly available in commercial products.

Baking soda. Homemade baking soda sprays are typically recommended to control powdery mildew. A common recipe calls for mixing 1 teaspoon of baking soda, 1 drop of liquid soap, and 2 quarts of water. A spray of baking soda and oil can also be used to control powdery mildew: Mix 1 tablespoon baking soda, 1 tablespoon narrow-range oil, 1 drop of detergent, and 1 gallon of water. Commercial baking soda sprays are also available.

Sulfur. Both sprays and dusts containing sulfur are available to control plant diseases caused by fungi. Sulfur binds with

Common Disorders of Vegetable Crops

Condition	Crop	Symptoms	Cause
Black heart	Beet, turnip	Darkening in center, sometimes hollow	Boron deficiency; sometimes potassium or phosphorus deficiency
	Potato	Same	Lack of oxygen
	Celery	Same	Fluctuating soil moisture; calcium deficiency
Blasting	All flowers	Buds or flowers drop prematurely	Soil too wet or dry
	Onion	Leaf tips bleach, brown, and wither	Bright light after cloudy, wet conditions
Blossom-end rot cucurbits	Tomato, pepper,	Dark, sunken area at blossom end of fruit	Dry conditions after wet; calcium deficiency
Cracked stem	Celery	Stem cracks	Boron deficiency
Hollow heart	Crucifers	Hollow stem	Boron deficiency
Sunscald	Tomato, pepper	White area appears, blisters before secondary rotting occurs	Excessive loss of foliage; heavy pruning or trellising of tomatoes
Tipburn	Lettuce, potato	Leaf tips brown	Bright light after cloudy, wet conditions; potassium deficiency; calcium imbalance

the spores to prevent them from germinating. To be effective, the sulfur must be present on all susceptible leaves before the fungi invade; therefore, it must be used at 7- to 14-day intervals during damp weather to protect new foliage. Sulfur harms the beneficial mites that live on leaves of fruit trees and other plants; therefore, it should be used with caution. It also shouldn't be used when temperatures are over 80°F (27°C) because it can damage leaves. Because some plants can't tolerate sulfur, always check labels before using it.

Copper. Sprays containing copper (fixed copper, Bordeaux mixture) are sold to control bacterial diseases and some fungal diseases. Copper sprays can damage leaves and must be used according to instructions on the package. Copper is also a heavy metal and can build up in the soil if used continually. Where frequent spraying with copper is required to control a disease, it would be better to concentrate on finding ways to prevent the problem in future.

A Word of Encouragement

In your garden, you probably won't have the chance to get to know more than a few diseases that are common problems in your region. Organic gardeners know that diseases aren't very common. Healthy plants growing in a healthful environment are resistant or tolerant to most pathogens. They have a lot of unseen help from beneficial fungi and bacteria, in the air and in the soil, that suppress the pathogens. A balanced, organic garden is your best insurance against disease problems.

The most common diseases are listed above, with a brief description of the most obvious symptoms. Several diseases have similar symptoms; this table is meant as a guide to help you narrow down the possibilities. You will need to read the detailed descriptions given in the disease entries to make a final diagnosis.

Defeating Plant Diseases the Organic Way

Joan Benjamin and Deborah L. Martin

Whether it's rust on your roses or powdery mildew on your pumpkins, the ugly symptoms and disappointing crops caused by plant diseases have no doubt resulted in suffering for you (or rather, your plants). All kinds of plants, from mighty oaks to dainty annual flowers, are susceptible to the bacteria, fungi, and viruses that cause plant diseases. But that doesn't mean that you're doomed to diseased plants. You have lots of solutions, from disease-prevention planting plans to homemade remedies that can help you keep your vegetables, flowers, lawn, trees, and shrubs healthy.

Prevention is the best defense. It's easier to keep your plants disease-free than to try to cure them once they're infected. The best way to ensure your plants' health is to provide a healthy, fast-draining soil and appropriate growing conditions. Organic matter is the key to soil health and good drainage, so make sure that your soil has plenty.

The right plants can make disease prevention much easier. Choose disease resistant varieties whenever possible and match plants to the conditions in your garden.

Continued →

Adopt a disease prevention routine. When you walk through your garden, always be on the lookout for discolored leaves or other symptoms that just don't look right. If you see diseased leaves, pluck them off of your plants to prevent the disease from spreading. If necessary, remove a sickly plant before it infects its neighbors.

If you're growing fruits and vegetables, be sure to clear out plant debris after your harvest so that you don't give diseases a place to camp out, waiting for spring to strike again. (Don't work in the garden when plants are wet because water is a great disease conductor.) Compost any healthy material you remove from your plants, but be sure to throw any diseased leaves or stems into the garbage.

Doctor plants with care. In some cases, you can use sprays, powders, and other treatments to discourage disease or prevent it from spreading. When treating plants with a spray or powder, keep these simple rules in mind:

- **Test your treatments.** Try both homemade and store-bought cures on one leaf first to test your plant's sensitivity. It's like trying out a stain removal product on a small area before going whole hog. Wait a day to see if any problems turn up before you treat the entire plant.
- **Stick sprays in place.** If your spray rolls off your plants' leaves, it isn't going to do much good. Try adding a drop of liquid soap (with as few additives as possible) to your sprays to break up surface tension on leaves and help the mix stay in place.
- **Get started early.** First thing in the morning is the best time to spray. Don't use sprays late in the day when humidity is building up or dew is settling since these are prime conditions for some diseases to spread.
- **Watch the weather.** Don't apply treatments in windy or rainy weather. If it rains after an application, plan to reapply.
- **Keep cool.** Don't treat plants when temperatures are above 90°F. Some sprays can burn leaves at high temperatures.
- **Cover up.** Remember to use any spray or powder with caution, no matter how harmless it may seem. Wear long sleeves, goggles, gloves, and long pants. Use a dust mask with powders and a respirator with sprays that may irritate your throat or lungs.
- **Store disease-control products carefully.** Always label containers and keep them out of the reach of children and pets. Do not expose sprays or powders to light or heat.

PLANT DISEASE PRIMER

How can you tell when your plants are sick? Common symptoms include yellow or blotchy leaves, distorted growth, patches of mold, and dying leaves or plants. But other problems, like a nutrient deficiency or lack of water, may cause these symptoms too. Making the right diagnosis can be tricky.

If you think your plants are diseased, compare their symptoms to those described below for some common plant diseases. Then, check the symptoms caused by lack of nutrients. Chances are, you'll figure out what's troubling your plants. If you're stumped, take a sample of the plant to your local Cooperative Extension office and ask for help in diagnosing the problem.

Blights. Spreading brown spots or patches on leaves can be a clue that your plants have a fungal blight. The fruits may shrivel and rot. Other types of blight may look like a white or gray growth on the flowers.

Downy or powdery mildew. If your plants have a white powdery coating on the leaves, the problem is powdery mildew. If the fuzzy coating is on the undersides of the leaves, downy mildew may be the cause. Various fungi cause these diseases, which can affect a wide range of plants.

Mosaic. Mosaic is a viral disease that causes a range of symptoms including mottled leaves, twisted growth, and stunted plants.

Rust. If your plants look as if they're covered with rust, the cause is rust fungi.

Stem, root, and crown rots. These fungal diseases cause stems, crowns, and/or roots to become soft. Affected parts often turn brown or black or look water-soaked. Plants may be stunted or wilted.

Wilts. Both bacteria and fungi can cause wilt diseases. The common symptoms are yellow leaves and wilted plants. Suspect wilt diseases especially if plants wilt suddenly even when the soil is fairly moist.

Compost Tea Cure-All for Plants

To blast away blight in the vegetable garden, start your plants off with a few sips of compost tea. That's the advice of Steve Peters, agricultural planning associate for Seeds of Change, an organic seed company. "I have used compost tea as a preventive measure—it's pretty remarkable," says Steve, who says he's been pleased with the success even with plants like tomatoes and potatoes that are susceptible to the fungal diseases early blight and late blight.

Ingredients and Supplies

5-gallon bucket
Good-quality, finished compost
Fine-screened strainer
Backpack or pump sprayer

Directions

1. Fill the bucket halfway with compost, then add an equal amount of water, and stir.
2. Continue to stir the mix every other day with a large stick or branch, letting the stuff steep for about 1 week or until the liquid is mahogany colored.

Symptoms of Disease

The following list of symptoms and causes will help you decide whether you have a cultural disorder; fungal, bacterial, or viral disease; or if your plants may be infested with nematodes.

Cultural Disorders

A variety of conditions can cause cultural disorders, including nutrient deficiencies, improper pH, poor soil drainage, under-or-overfertilization, and improper light exposure. The symptoms of these problems generally cause chlorosis, or yellowing, of the leaves. Chlorotic areas in most cases eventually turn brown or die. Look closely to see if the yellowing affects all of the leaves or only the youngest or oldest ones. Cultural disorders can also result in yellowed or browned leaf edges, yellowing between the veins of the leaves, or in irregular or mosaic spots or patterns.

Fungal Diseases

Plants infected with fungi can develop a variety of symptoms, depending on the type of disease involved. Look for pale patches on the leaves that may or may not be associated with rust-colored, powdery-looking patches on the upper or lower surface; round or irregular spots or blotches of chlorotic (yellowed) tissue that darken with time and dead spots or blotches on leaves are other signs of fungal diseases. Also look for water-soaked or greasy-looking spots on leaves or stems, or black, rotted-looking streaks or blotches. In this case, once the fungi have rotted all the way around the stem (girdle it) the afflicted stem will wilt and die. Seedlings that die suddenly, rotting at the soil surface and falling over, probably have been afflicted with a common fungal disease called damping-off.

Bacterial Diseases

Plants that exhibit the following may have a bacterial disease of some kind: rotted leaves, stems, branches, or tubers, often accompanied by a foul odor. When cut, afflicted plant parts often exude sticky-looking, yellowish or whitish masses of bacteria. Other symptoms of bacterial diseases include wilted leaves or stems, or large, irregularly shaped galls near the soil line on roots and stems.

Viral Diseases

There are many different viral diseases, all of which cause slightly different symptoms. Look for some or all of the following symptoms if you suspect your plants may be infected with a viral disease. Virus-infected plants generally exhibit overall poor plant performance, specifically, small, stunted plants, leaves, and blossoms. Blossoms and leaves may be disfigured, or the plant may develop shoots that branch abnormally, creating witches'-brooms. Many viral diseases cause a yellow-and-green mottling pattern on leaves, stems, or even blossoms. Also look for puckered, rolled, or extremely narrow ("shoestring") leaves and chlorosis (yellowing of leaves), specifically irregular yellow spots on leaves, often accompanied by leaf curling or excessive branching.

Nematode Infestation

Nematode-infested plants are stunted and grow poorly. Root knot nematodes form galls or swellings on plant roots, which you will find if you dig the plants to examine the roots. Other species cause deformed leaves or stems. Put nematodes at the bottom of your list of suspects. If no other explanation seems to fit, check the possibility that your plants have nematodes.

3. Let the solid material settle to the bottom of the bucket and run the liquid through a fine screen. "You're basically decanting it," Steve says. "You've got a lot of solid material in there and if you're not careful, it can clog your sprayer. With careful pouring, it should be okay."
4. Pour the strained mixture into a backpack sprayer. Or pour it into a spray bottle and store the remainder in the bucket. Make sure that you label the bucket.
5. Spray young plants about once a week. The tea has a double benefit, Steve says. "It also acts as a foliar (leaf) fertilizer."

Yield: About 2½ gallons of compost tea.

Seedling-Ease Chamomile Tea

It's sad to watch beautiful little seedlings suddenly wilt and die—cut down before their time by a disease called damping-off. There is no cure for this soil-dwelling fungal disease, but according to Penny King, an herbal educator, you can prevent damping-off with chamomile tea. Penny saw her share of damping-off when she grew herbs commercially as the owner of Pennyroyal Herbs in Georgetown, Texas. She found that she could prevent damping-off losses simply by watering her seedlings with chamomile tea.

Ingredients and Supplies

1 cup water

2 teaspoons dried chamomile flowers

Strainer

Directions

1. Bring the water to a boil, then remove from heat and stir in the chamomile flowers. Cover and allow the mixture to come to room temperature.

Continued ➔

2. Strain the liquid and use full strength. Dampen potting soil mixtures with the tea before you plant your seeds. And then water with the tea blend, spraying the soil lightly each day with the chamomile tea instead of water.

Yield: About 1 cup of Seedling-Ease tea

Note: You can also use chamomile tea to water cuttings and to soak seeds prior to planting.

Variations: For a slightly stronger antifungal tea, add 2 teaspoons of dried horsetail (*Equisetum arvense*) to the water and chamomile flowers. (You can buy dried horsetail from many mail-order herb suppliers.)

Use this stronger tea solution on established plants that exhibit signs of fungal disease. Repeated applications of the tea can cure many fungal problems. Be sure to spray both sides of the leaves thoroughly.

"HOT" COMPOST HELPS, TOO

Adding "hot" compost to your seed-starting mix also helps protect your seedlings from disease, says compost-and-disease expert Harry Hoitink, Ph.D., professor of plant pathology at the Ohio State University. Just amend a standard peat/vermiculite starting mix with at least 5 percent mature compost, preferably from a pile that has recently been heated. Any disease organisms in the compost materials are killed in the hot pile. Then, as the compost cools, beneficial disease-preventing microbes reproduce quickly and get the upper hand.

MORE CHAMOMILE TEA FOR SEEDLINGS

"Chamomile tea definitely works," says Steve Peters, agricultural planning associate for Seeds of Change, an organic seed company. Even broccoli and other brassica seedlings, which often fall prey to the low light and lack of air circulation in greenhouses, will survive with a dousing of strong chamomile tea.

Steve mixes 1 cup of dried chamomile flowers with 1 quart of water to make his tea. He suggests steeping the brew for at least an hour, explaining that "the stronger it is, the more effective it is." He adds that the taste of this strong tea, should you try it, would probably be too bitter to drink.

Spray the seedlings as soon as they appear. Continue spraying daily until the seedlings are past the danger point (about two weeks).

Using sterile soil for seed-starting, rather than garden soil or potting soil that has already been used, should be your first step in preventing the damping-off fungus, Steve advises. And keeping soil moist, rather than soaked, is also important.

Andy's Simple Alfalfa Solution

Try giving your flowers and vegetables a shot of alfalfa for a nutritional boost that makes plants stronger and more able to fight off diseases. You can prevent most types of fungal diseases if you spray your plants with alfalfa tea early in the season, says Andy Lopez, founder of the Invisible Gardeners of America. And what if you don't have a field of alfalfa growing nearby? Don't worry—alfalfa is available as a powdery meal that you can buy from farm or organic garden suppliers.

Ingredients and Supplies

1 cup alfalfa meal

1-gallon bucket

Cheesecloth

Biodegradable dishwashing liquid

Backpack or pump sprayer

Directions

1. Add the alfalfa meal to a bucket of water. Let it sit for a few hours, then strain the mixture through cheesecloth.
2. Add a dash of biodegradable dishwashing liquid to help the tea stick to plant leaves.
3. Fill the spray bottle with the mixture and spray plants.

Yield: About 1 gallon of alfalfa solution

WELL-FED LEAVES RESIST DISEASE

Just as people take a daily vitamin to keep from getting sick, plants stay healthier when they get occasional doses of nutrient-rich organic sprays like Andy Lopez's alfalfa solution. Applying foliar (leaf) sprays may not prevent disease organisms from attacking your plants. But well-nourished plants are more likely to keep growing and producing even if they are suffering from disease. You may not notice the disease symptoms until very late in the season.

When you spray nutrient solutions to help prevent disease, it's best to spray in the early morning, especially if you live in a humid climate.

Rhubarb Spray to the Rescue

For a garden rescue straight from the garden, try Mary Perlmutter's recipe for a rhubarb spray that destroys fungal diseases as well as aphids and June bugs. "If I see signs of a disease that's just starting, I give it a shot of the rhubarb mixture," says author and organic gardener Mary, who has experimented for years with using plants like rhubarb and garlic for solving disease problems in her rural Canadian garden.

Ingredients and Supplies

½ cup rhubarb leaves (about 6 leaves), crushed

3 quarts water

Pot (for boiling)

Blender (optional)

Cheesecloth or fine-mesh sieve

Pump spray bottle

Directions

1. Cut or tear rhubarb leaves into small pieces. Mary uses rhubarb from her garden, but if you need to buy some, you may find rhubarb with its leaves intact at a farmers' market. Most supermarkets sell it with the leaves removed.
2. Place the leaves in the water and bring it to a rolling boil.
3. Steep the leaves for at least an hour. Mary says she likes to steep them overnight.
4. Shred the boiled leaves further in a blender, if desired. Strain the solution through the cheesecloth or sieve and pour it into a spray bottle. Add the leaf residue to your compost pile.
5. Spray affected plants thoroughly.

Yield: About 3 quarts of rhubarb-leaf spray

Note: Mary suggests making a new batch of rhubarb spray each time you want to spray. "I have been known to strain it and put it in the freezer," she says, "but I prefer a fresh mixture." She adds that you can also keep leftover spray—carefully labeled—in the refrigerator; for a freshness check, be sure that it doesn't have an off odor. Or, if you have a spot where you'd like to lower the pH in your garden, just pour the excess rhubarb spray into your compost or soil for a slightly acidic boost.

Hello Jell-O Seed Starter

To get her flower and vegetable seeds off to a disease-free start, organic gardener Marion Hess of Northville, Michigan, believes in a sweet approach. She sprinkles her seeds with Jell-O powder. She also feeds her young plants with Jell-O as they grow.

Ingredients and Supplies

Peat pots
Potting soil
Seeds
1 package Jell-O powder, any flavor with sugar
Powdered skim milk, in amount equal to Jell-O (optional)
Salt shaker or other sprinkling device
Newspaper

Directions

1. Fill the peat pots with potting soil and place 2 seeds in each pot.
2. Fill the salt shaker with the Jell-O powder (and powdered skim milk, if desired, for extra calcium) and sprinkle the powder lightly on top. Gently press down the powder and cover lightly with soil.
3. Moisten the soil and cover it with damp newspaper.
4. After 4 days, remove the newspaper and keep the seeds in a warm area with temperatures of 55° to 65°F.

Note: Should your friends snicker about your plant's snacking habits, just tell them that it makes sense when you think about what's in Jell-O, Marion says. "The gelatin helps the plant hold water, and the sugar feeds the organisms in the soil."

JELL-O DIET PLAN FOR PLANTS

Even after your plants are up and running, Jell-O can still help keep them healthy, Marion Hess says. "In any organic, liquid fertilizer, such as compost tea, I always add Jell-O," she reveals. Add ½ to 1 teaspoon of Jell-O powder to 1 gallon of fertilizer in a bucket. Mix well and use the mixture immediately to prevent thickening. Pour directly on the soil. Because of possible thickening, you don't want to use a spray bottle with this mixture, Marion warns.

Many adventurous gardeners use Jell-O for their houseplants, but Marion says it's just as great at fighting off fungal diseases in outdoor plants. And, she adds, while any flavor will do, lemon's her top choice, because she thinks the citrusy odor repels some bugs.

Compost Your Lawn Problems

Looking for a magic pill to cure all your lawn ills? Compost comes mighty close—it will feed your lawn, improve the soil structure, and prevent diseases! And it doesn't take very much compost to do all this, according to Cornell University plant pathologist Eric Nelson, Ph.D., who has been researching compost's ability to prevent lawn diseases. Here's his recommendation, based on the latest research.

Ingredients and Supplies

Composted poultry manure
Cyclone or drop-type fertilizer spreader

Directions

1. If you have chickens, you can make your own poultry compost. If a flock of hens isn't for you, buy composted poultry manure bagged at nurseries and garden centers. Why poultry manure? Eric says that of all the composts Cornell has tested on lawns, composted poultry manure seems to work best for suppressing diseases.
2. Apply 10 pounds of compost per 1,000 square feet of lawn about once a month during the growing season. Regular applications of this "black gold" can prevent a whole host of diseases that strike both cool and warm season grasses, including snow mold, brown patch, dollar spot, pythium blight, necrotic ring spot, red thread, and summer patch.

Note: If you use homemade compost, screen it to remove any chunks before applying it with the spreader. The compost will go through the screen and the spreader best if you let it dry out a little before you try to screen it.

DISEASE-PROOF YOUR GARDEN WITH A DOSE OF COMPOST

Lawn grass isn't the only plant that gets healthier when you treat it with compost. According to renowned compost-and-disease expert Harry Hoitink, professor of plant pathology at the Ohio State University, extensive international research has now proven that you can protect your garden crops from diseases by applying compost regularly. To get maximum disease-preventing power, Harry says to "use a surface mulch of slightly immature compost in your garden beds."

Spicy Garlic Garden Spray

Get the best results from garden sprays by catching problems right away, advises Mary Perlmutter, author of *How Does Your Garden Grow... Organically?* Mary vigilantly patrols her garden each morning for signs of distress. If she spies any trace of fungal disease (rust on a hollyhock or blackspot on a rose, for instance), she prepares this potent garlic cure, applies it, and sees improvement almost immediately.

Ingredients and Supplies

3 cloves garlic, crushed

1 onion, peeled and minced

1 teaspoon Jalapeño pepper, crushed

Fine-meshed sieve or cheesecloth

Pump spray bottle

1 drop dishwashing liquid or 2 tablespoons vegetable or horticultural oil (optional)

Directions

1. Steep garlic, onion, and pepper in 1 quart of warm water for 1 hour or longer.
2. Strain the mix through a sieve or piece of cheesecloth and retain the liquid.
3. In the spray bottle, dilute 1 part of the strained liquid in 4 parts warm water and add the soap or oil, if desired. (Adding oil will help the mixture remain on the plants longer; adding soap will improve spray coverage on leaves and stems.)
4. Mist plants lightly.

Yield: About 1 quart of spicy spray concentrate

BE WARY, SAYS MARY

You may not have five hours each morning to survey your vegetables, flowers, perennial plants, and fruit trees, as Mary Perlmutter does. But, she points out, it would be a shame not to take a quick walk through your yard at least once a day to find out how your crop is growing. That way, you can nip problems in the bud before diseases turn into death sentences.

"I check the plants," Mary explains. "I don't touch every single plant; but if I see a plant that's looking sad, I will examine it. Usually, it's from lack of water." Mary's biggest problem may be summer drought, but she keeps an eye out for other problems, too. She looks for yellowing, white powder, strange patterns on leaves, dull leaves that should be shiny, curling leaves, and any other symptoms that suggest illness or other problems.

Early action, whether it's spraying to stop disease from spreading or careful pruning of diseased leaves, can keep small problems small. "You have to be in touch with all parts of the garden," Mary says.

MORE GREAT GARLIC IDEAS

If the idea of garlic in the garden grabs your interest, try these variations. Horticulturist and organic gardener Howard Garrett recommends the first two sprays for fighting diseases and insects:

Garrett's garlic/pepper blend. Liquefy two garlic cloves and two hot peppers in a blender that is half-filled with water. Strain out the garlic and pepper bits, then mix the remaining liquid with enough water to make 1 gallon of spicy concentrate. For the final spray, use ¼ cup of the concentrate for each gallon of water. Two tablespoons of molasses will help the mixture adhere to leaves.

Plain and simple garlic juice. For a plain garlic juice, use three garlic cloves and follow the directions above—it makes a great additive for any garden-disease or insect-pest spray.

For extra garlic power in his garden, Andy Lopez goes a different route. Andy is the founder of the Invisible Gardeners of America, an organization which provides education on organic gardening techniques to its 6,000 members. Here's his recipe for a fungus-free garden.

Get growing to fight fungus. Andy grows the pungent herb around vulnerable plants, explaining that the garlic aroma provides a fungus-free environment. Andy adds that "garlic has been around for centuries as a fungal control."

Garlic has so many uses that you'll want to have lots of it around. Growing your own garlic is an easy and economical way to keep a steady supply of this useful bulb on hand, and it lets you try different kinds of garlic for cooking and for pest and disease control.

Start with whole bulbs from a local grower. Separate the individual cloves and plant them in mid-fall in full sun and well-drained soil. Set the cloves 1 to 2 inches deep and 6 to 8 inches apart. Harvest in early July when most of the leaves have turned brown, and lay the plants in a dark, dry spot to cure for several weeks. Trim leaves and roots and brush away excess soil, then store in cool, dry conditions.

Mighty-Milk Tomato Blight Cure

To ward off common tomato diseases, like early blight, try a sprinkling of powdered milk when you set out the tomato transplants. This simple suggestion comes from organic gardener Marion Hess, who is a special contributor for Prodigy's on-line gardening newsletter *Prodigy Gardens Newsletter.* Marion credits milk with her amazing tomato track record of no diseases, ever. "I have never even had to rotate my crop," she marvels. And the technique is gentle, Marion assures. "It won't hurt anything in your yard."

Ingredients and Supplies

¼ cup plus 2 tablespoons powdered nonfat milk
¼ cup Epsom salts (optional)
1 shovelful of compost (optional)
Salt shaker or other sprinkling device
Hand trowel

Directions

1. Prepare your garden site or planting container for planting by digging a hole.
2. Use the shaker or your hand to sprinkle the powdered nonfat milk into the planting hole. Add the Epsom salts and compost or composted manure, if desired. The Epsom salts and compost will boost your plant's overall growth and disease resistance, Marion says.
3. Mix the ingredients into the soil with the hand trowel.
4. Set your tomato plant in place and refill the hole with soil.
5. Sprinkle about 2 tablespoons additional powdered nonfat milk around the plant, then mix the milk into the soil with the trowel.
6. Add more powdered milk every few weeks throughout the growing season by sprinkling about 2 tablespoons of the powder on top of the soil. When you use your trowel (or a spade or garden fork) to mix the powder into the soil, take care not to damage roots that are growing near the soil surface.

MULCH TOMATOES IN TO KEEP DISEASE OUT

A layer of mulch doesn't just keep moisture in the soil; it also can protect your tomatoes from diseases, says Dr. Frank Killebrew, extension plant pathologist at Mississippi State University. "The mulch provides a physical barrier between soil and plant surfaces and reduces the amount of disease inoculum that is splashed onto foliage, stems, and fruits during rainy periods," explains Dr. Killebrew. Mulching can prevent tomato (and cucumber) rot diseases. He suggests using black plastic or organic materials such as bark, composted sawdust, oat straw, or pine needles for mulch.

Wipe Out Black Spot with Tomato Leaf Tonic

When black spot attacks her roses, organic gardener and author Mary Perlmutter uses ingredients that are plentiful all summer long: tomato leaves and onions! Mary steeps the leaves and onion in alcohol. The sharp-smelling solution not only discourages the black spot fungus but aphids, asparagus beetles, and scale insects as well.

Ingredients and Supplies

10 tomato leaves
1 medium-size onion, finely chopped
½ cup rubbing alcohol
Cotton batting
Stick, about the size of a chopstick

Directions

1. Pick 10 tomato leaves from a healthy tomato plant and chop them into small pieces.
2. Combine the onion with the tomato leaves in the rubbing alcohol. Steep the mixture overnight.
3. Make a cotton swab by wrapping a piece of the cotton batting around the stick. The idea is to make a swab that is large enough to let you apply the mixture easily.
4. In the morning, remove any diseased leaves from your roses. Dip the swab in the tomato-onion solution and wipe the entire plant, including the tops and undersides of all the leaves.

Yield: About ½ cup of black spot-stopping Tomato Leaf Tonic

BEATING BLACK SPOT

Black spot (*Diplocarpon rosae*) is a disfiguring fungal disease that infects roses during warm, wet weather. The disease causes black spots ringed with yellow on rose leaves. While black spot is rarely fatal, a severely infected plant may drop all of its leaves.

Luckily, you can thwart black spot with good gardening practices. Every time you visit your garden, clean up fallen leaves and organic debris to remove places where black spot spores collect. While you're there, prune off and destroy infected leaves and seriously infected canes.

You can also keep black spot off plants by being careful not to splash spore-laden, muddy water on them when watering. A mulch of disease-fighting compost actually kills spores in the soil and keeps them from splashing onto plants.

Good air circulation also prevents black spot spores from taking hold. To open the center of rose bushes to air and sun, carry pruners on garden visits and cut out any inward-growing shoots. Growing roses in full sun and spacing them far enough apart for adequate air circulation can stop black spot troubles before they start.

Baking Soda Blitz

For a disease fighter that's cheap, easy, and proven effective, look no further than your kitchen cabinet. This recipe, offered by Dr. Thomas A. Zitter, a professor in the Cornell University Department of Plant Pathology, includes lightweight oil that acts as a spreader-sticker to help the baking soda stay on leaves. By keeping the baking soda on the leaves, the oil makes the spray more effective.

Use this recipe when you have to spray only occasionally—some plants may be injured by repeated applications of oil.

Ingredients and Supplies

1 tablespoon baking soda

1 tablespoon horticultural oil

1 gallon water

1-gallon backpack or pump sprayer

Directions

1. Mix the baking soda, oil, and water in the sprayer.
2. Spray each plant completely, including the tough-to-reach spots like the undersides of leaves, says Dr. Zitter. "Some of these things (fungi) do very well on the underside of a leaf. If you spray only the top, you will reduce the population by half—if you're lucky—and you will have a new set of spores."

Yield: About 1 gallon of fungus-fighting spray

Variation: Dr. Zitter points out that while baking soda is great, its near relation, potassium bicarbonate, performed even better in studies and the Environmental Protection Agency (EPA) has approved it as a commercial home and garden product. (Look for potassium bicarbonate at garden centers.)

Deluxe Baking Soda Spray

Instead of mixing separate sprays for diseases and insects, consider using Dennis Glowniak's deluxe combo spray, which works for both. Spray weekly and it's "good-bye pests!" promises Dennis, president of the California Organic Garden Club.

Ingredients and Supplies

1½ tablespoons baking soda

1 tablespoon insecticidal soap

1 tablespoon canola oil

1 cup plus 1 gallon water

1 tablespoon vinegar

Backpack or pump sprayer

Directions

1. Mix the baking soda, soap, and oil with 1 cup of water.
2. Add the vinegar. Don't mix the vinegar in until last or the mixture may bubble over.
3. Pour the mixture into the sprayer and add 1 gallon of water. Shake or stir to combine the ingredients.
4. Spray plants, covering the tops and bottoms of the leaves.

Yield: About 1 gallon of baking soda spray

BAKING SODA'S BEST AS A PROBLEM PREVENTER

You should always keep a simple solution of 1 teaspoon baking soda to a quart of water mixed and ready for action in your garden, states Dorothy Read, editor of *The Garden Sampler* magazine, which is based in Peru, Vermont. The spray stops fungal diseases on everything from roses to pumpkins, Dorothy claims.

Dorothy's recipe is simple and effective at combating fungal diseases such as black spot and powdery mildew, but there are other versions you can try as well. No matter which recipe you use, be snappy about it, Dorothy urges, because while bicarbonates stop the spread of fungi, they can't clean up a diseased mess. Dorothy explains that baking soda works best as a preventive—if you've had trouble with fungal diseases in the past, start spraying susceptible plants before disease symptoms start and continue at weekly intervals to prevent the problem.

Powdery Mildew Solution

Here's a new twist on the popular baking soda-and-oil mix for controlling powdery mildew. Iowa-based garden writer Veronica Fowler offers this version that uses Murphy's Oil Soap. "The baking soda alters the pH of the leaf, making it more difficult for powdery mildew to form," Veronica explains. "The oil soap serves as a spreader-sticker, so that the mix spreads more evenly and doesn't wash off as readily."

Ingredients and Supplies

1 gallon warm water

3 tablespoons baking soda

1 tablespoon Murphy's Oil Soap

Directions

1. Mix all ingredients well.
2. Spray plants when you spot the very first sign of powdery mildew—a grayish coating on leaves. Coat both sides of leaves thoroughly. Spray every 7 to 10 days until daytime temperatures start getting into the 70s.

Yield: About 1 gallon of Powdery Mildew Solution

Note: On plants with chronic powdery mildew problems, use this spray as a preventive. Spray once or twice in very early spring before any sign of disease appears. If you notice powdery mildew, take action to stop its spread. Remove all affected leaves and spray with a baking soda solution. Prune or thin to improve air movement around the foliage. Finally, make sure the plant

isn't stressed by drought or other problems; stressed plants seem more susceptible to infection.

PLANTS PESTERED BY POWDERY MILDEW

The fungal disease powdery mildew is ugly but it seldom does serious harm. If you're growing a plant that's susceptible to the fungus—check the list below—and don't like how it looks, keep baking soda and Murphy's Oil Soap handy for a quick preventive spray.

Trees and Shrubs

- Crabapples (*Malus* spp.)
- Crape myrtle (*Lagerstroemia indica*)
- English oak (*Quercus robur*)
- Euonymus (*Euonymus* spp.)
- Hackberries (*Celtis* spp.)
- Honeysuckles (*Lonicera* spp.)
- Lilac (*Syringa vulgaris*)
- Privets (*Ligustrum* spp.)
- Roses (*Rosa* spp.)

Flowers

- Bee balm (*Monarda didyma*)
- Dahlias (*Dahlia hybrids*)
- Delphinium (*Delphinium x elatum*)
- Phlox (*Phlox paniculata*)
- Zinnia (*Zinnia elegans*)

Spray Away Brown Patch in Lawns

If your lovely green lawn develops brown or yellow rings or patches that die out, brown patch may be the culprit. A variety of Rhizoctonia fungi causes this disease; some species thrive in cool weather, while others affect grasses in warm weather.

If brown patch plagues your lawn, fight back with this formula from John Dromgoole, owner of Garden-Ville in Austin, Texas. Follow up with John's suggestions for correcting water and fertilizer problems or the disease will return.

Ingredients and Supplies

- 1 rounded tablespoon baking soda or potassium bicarbonate
- 1 tablespoon horticultural oil
- 1 gallon water

Directions

1. Mix all ingredients thoroughly.
2. Spray lightly on your lawn. Avoid overuse or drenching the soil with baking soda.

Yield: About 1 gallon of spray for battling brown patch

Note: John says potassium bicarbonate, available in garden centers, is the best choice for this spray. Unlike baking soda, potassium bicarbonate leaves no salt residue in the soil.

COMPOST STOPS BROWN PATCH COLD

How can you tell if your lawn has brown patch? Take a look at your lawn care techniques. John Dromgoole says, "The disease is generally caused by poor drainage, too much rain or irrigation, and/or too much nitrogen fertilizer. Another symptom is that the leaves easily pull loose from the runners."

Aerate to improve the movement of air, nutrients, and water through the soil. And fix drainage problems by filling in low spots or installing drain tiles in your yard. To permanently solve brown patch problems, John suggests applying a half-inch layer of finished compost to your lawn. The microbe trichoderma, which exists in compost, is a powerful deterrent to brown patch.

Lawn Fungus Fighter

If your lawn develops 2- to 6-inch-diameter reddish-brown spots during the hot, sticky days of summer, it may have a fungal disease called Fusarium blight. Rather than watch those spots turn tan and then yellow as the grass roots die, follow the lead of Robert Redmon, a director of grounds management for the University of Alabama in Huntsville.

When part of the lawn Robert tends became diseased and developed unstoppable brown patches, he made a concoction with two fungus-busting agents: bleach and oil. This mix will help you get temporary control of a fungus-infested lawn during high stress periods. Then you can use cultural controls for a long-term solution. Robert says that he has used this spray primarily for fescues, but adds that it should work equally well for other cool-season grasses.

Ingredients and Supplies

- 1 ounce household bleach
- 2 ounces horticultural oil or a surfactant (the amount according to the label)
- 4 gallons water
- Pump spray bottle or hose-end sprayer
- White Dutch clover seed
- Goggles
- Rubber gloves

Directions

1. Mix the bleach and oil with water in the sprayer. (This mix will cover about 1,000 square feet of lawn.) Be very careful when you handle bleach. Wear goggles, rubber gloves, and long sleeves and take care to avoid splashing when you pour the bleach.

Continued →

2. Spray the mix on affected areas starting when temperatures consistently reach the mid-60s at night.

3. Fusarium blight is a disease that migrates from the soil to plant parts and then spreads as the temperature and humidity increase. You'll need to reapply the spray monthly to keep the blight under control.

4. When you reseed the area in the fall with fescue or other grass seed, include some clover—¼ to ⅓ pound of clover per 50 pounds of fescue seed, Robert says. That's enough for approximately ½ acre of overseeding.

Note: This recipe should work where fungicides have failed, Robert claims. "I had used a fungicide in another spot that didn't seem to be doing the job, but the bleach-and-oil mixture seemed to take care of it," he states.

Variation: If you want a bleachless control for fusarium blight and other diseases, use compost. Adding compost to your lawn may control some diseases because organic matter increases the number of beneficial microorganisms in the soil. A healthy population of beneficial microorganisms can crowd out disease microorganisms or, in some cases, even kill them.

To add compost to your lawn, screen it first to remove any large pieces, then apply it using a cyclone or drop-type spreader. If you prefer to use a sprayer, mix up a hearty compost tea solution and spray it on.

LAWN CARE PRESCRIPTION

Robert Redmon has more advice for a healthy lawn. Follow these tips and you won't have to worry about finding cures for fungal diseases.

- Plant resistant grass varieties.
- Once your grass is growing, make sure that it gets enough water (1 inch per week).
- Don't water your lawn at night, when it is sure to stay damp, because wet conditions help fungi spread.
- Mow your lawn when it's dry, and leave it alone when it's wet to avoid spreading fungi.
- Fertilize with an organic fertilizer.
- Aerate your lawn so that water and air can move easily through the soil.

Dr. H. Arthur Lamey, a plant pathologist at North Dakota State University Extension Service in Fargo, also suggests that you avoid evening watering. He adds these precautions to ward off the fungal spores that, he says, plant themselves almost like seeds.

- Don't mow grass too short.
- Remove excess thatch.

Dual-Purpose Garden Spray

A garden product that you may already have can help your plants fight off fungal diseases. Antidesiccants (or antitranspirants) are best known as the stuff you spray on Christmas trees or wreaths to hold in moisture and make them last longer. But studies show that the sprays can also fight off rust and powdery mildew, says landscape consultant Mark Whitelaw, a consulting rosarian for the American Rose Society.

Ingredients and Supplies

Antitranspirant or antidesiccant

Backpack or pump sprayer

Directions

1. Antitranspirants are sold at nurseries under various commercial names as a ready-to-use spray or as a concentrate that you'll need to mix up. Buy whichever is most useful to you. And don't let those long words scare you off—antitranspirants are virtually nontoxic and biodegradable. They work by creating a film on a plant's leaves.

2. When you spray, be sure to coat the tops and bottoms of leaves. Application techniques depend on which form you buy, Mark says, so read and follow label directions. By coating the leaves and stems, you block fungi from the leaves and/or give any fungal spores that are already there a coat, which prevents them from spreading. The film will not protect new growth, so reapply as needed, according to the label.

Note: Gardeners in cool, humid climates, like the Pacific Northwest and New England, boast success with antidesiccants in fighting the dreaded rose rust which thrives in their area, Mark says. At the same time, antidesiccants are popular with some in southern California's dry inland areas. "Antitranspirants are particularly effective against powdery mildew in areas where hot, dry conditions prevail during the day, but high humidity conditions exist at night and early morning," he explains.

WATER FIRST

Whether you're feeding your plants, using a foliar (leaf) spray, insecticidal soap, or any other man-made interference, getting out your hose or watering can should always be step number one. "Always, always irrigate before applying any chemical, of any sort, for any purpose!" Mark Whitelaw insists. "This puts less stress on the roots and foliage of the plant." If you don't water, you'll create conditions that can injure the leaves.

Fishy Foliar Spray

You can feed your plants and slow the spread of fungal diseases at the same time when you combine two ocean-going ingredients in a foliar (leaf) spray. Rick Estes, president of the

New Hampshire chapter of the Northeast Organic Farming Association, uses this nutrient-rich seaweed and fish emulsion "soup" when plants show the first symptom of disease. He also uses it during the growing season and at transplanting time to give plants an energy boost.

Ingredients and Supplies

- 2–4 tablespoons liquid seaweed
- 2–4 tablespoons liquid fish emulsion (sold at most garden centers and some discount chain stores)
- 1 gallon water
- Backpack, pump, or hose-end sprayer

Directions

1. Before you get started, take note: You may have to set your alarm clock. "You should get up before the sun hits the leaves to foliar-feed," Rick says. "Then the stomata (pore-like openings) of the leaves are open, taking in their moisture" for the day ahead.
2. Mix the liquids with 1 gallon of water in the sprayer and shake to blend thoroughly.
3. Spray generously, coating tops and bottoms of leaves. Stretch out your treatments. Don't spray more often than every 5 days, Rick suggests, even if plants show symptoms of a fungus or other ailment. "Always give the plants time to put the extra nutrients to work," he says. Rick recommends a dose of "nutrient and mineral soup" at transplanting time to help reduce shock and give plants a boost. For the squeamish (or those with curious cats): You can buy odorless fish emulsion.

Yield: About 1 gallon of Fishy Foliar Spray

SEAWEED STRAIGHT

For a last-ditch effort, when a treasured plant is nearly dead, Rose Marie Nichols McGee reaches for the liquid seaweed—a magical tip that she cherishes but hesitates to share. "I love liquid seaweed, but I'm always nervous about making too many claims for something. It's a tip we kind of pass on to friends," says the president of Nichols Garden Nursery.

So consider this a tip from a friend: To try to save a dying plant, make a circle of liquid seaweed around the trunk or stem and water it in. "If there's still something there, the seaweed gives it a booster."

Stick It to 'Em Molasses Spray

Molasses is anything but slow in fighting fungal disease in the garden, says organic gardener Andy Lopez, founder of the Invisible Gardeners of America. Don't worry about bugs, he says. "The plants absorb the molasses instantly. There's nothing left for the bugs!" Andy often mixes sulfured molasses with other organic garden sprays because, he says, the sugar feeds the plants and the sulfur is a natural fungicide.

Ingredients and Supplies

- 1 cup molasses
- 1 cup seaweed powder (optional)
- 1 cup powdered milk (optional)
- 1 cup rock powder (optional)
- 1 gallon warm water
- Backpack or pump sprayer
- Old panty hose
- Fine-meshed strainer

Directions

1. If you are using only molasses, stir thoroughly into warm water, and spray (skip steps 2 and 3). If you have any or all of the optional ingredients, mix the molasses and powders into a thick paste and follow steps 2 and 3.
2. Wrap about 1 cup of the paste in the panty hose and tie it into a ball. Place the ball in water and let it sit for 2 to 4 hours.
3. Strain the liquid and mist plants every few weeks. You can use it to stop the spread of fungal diseases or as a preventive.

Yield: About 1 gallon of molasses spray

Note: Pick the right sprayer for your garden's size. For a few plants or a small garden, a hand-held pump spray bottle will do the job. For a medium-size garden, a 1½-gallon pump sprayer will speed up the application. For bigger gardens, a backpack model not only holds more spray, but is easier to haul around.

Wash Away Fungi with Garrett's Spray

For a natural fungicide for ornamental plants, horticulturist and organic gardener Howard Garrett recommends his own homemade spray. Garrett's spray packs a punch because it contains four fungus-fighting ingredients. You can add even more antifungal power with additives like baking soda (see the variations below).

Ingredients and Supplies

- 1-2 cups compost tea (see "Compost Tea Cure-All for Plants" on page 878)
- 1 tablespoon liquid seaweed
- 1 tablespoon blackstrap molasses
- 1 tablespoon apple cider vinegar
- 1 gallon water
- Backpack or pump sprayer

Continued →

Directions

1. Mix the ingredients in the sprayer. The acidity of the vinegar helps to kill black spot on roses, powdery mildew, brown patch, and other nasty fungi, Howard says. And the manure-based compost tea has natural fungus-fighting abilities.
2. Spray during the cool part of the day. As tempting as it is to blast away, don't overdo it, Howard cautions. To avoid damage to leaves, mist plant lightly and be sure not to drip vinegar on the soil.
3. Clean your sprayer thoroughly after use.

Variations: To give your fungus-fighting spray even more "umph," add baking soda, potassium bicarbonate, or ¼ cup garlic tea. To make garlic tea, liquefy 3 bulbs of garlic in a blender and strain out the solids. Pour the garlic juice into a 1-gallon container and fill with water. Shake the garlic juice well before using.

COMPOST TEA KEEPS ORNAMENTALS FUNGUS FREE

Compost is an effective fungus fighter that can help control any fungal problems that your ornamental plants might have. Compost teas made from manure are more effective at fighting fungi than compost teas made from only vegetable matter. But don't use compost teas made from manure on edible plants. Animal manure may contain E. coli bacteria which could be transferred to your fruits, vegetables, and herbs if you spray them with the tea.

Making compost for compost tea is easy. Any mix of vegetable matter and animal manure (from herbivores or poultry) will do, but for the best results, make a compost pile that's about 80 percent plant matter and 20 percent chicken, cow, goat, horse, or sheep manure. Use whatever materials you have available for the plant matter, including leaves, hay, grass clippings, tree trimmings, food scraps, bark, sawdust, rice hulls, and weeds (before they set seed).

Oil on the Offense Spray

To prevent fungal diseases from taking hold in late winter and early spring when wet, rainy weather can mean trouble, spray your plants with diluted oil, suggests Andy Lopez, founder of the Invisible Gardeners of America. Andy uses oil on fruit trees, vegetables, roses, and most flowers. However, he cautions, oil benefits only shiny-leaf plants. Do not spray oil on fuzzy-leaf plants, which are vulnerable to burning.

Ingredients and Supplies

1 teaspoon oil (plant-based oil such as castor, coconut, or a light salad oil)

1 teaspoon liquid soap (any biodegradable dishwashing liquid or Dr. Bronner's Peppermint 18-in-1 Soap)

1 gallon water (with chamomile tea or compost tea, optional)

Backpack or pump sprayer

Directions

1. Mix the oil, soap, and water in the sprayer. Water is easiest, but if you've got it, substitute a few cups of chamomile tea or compost tea, both of which help inhibit disease, Andy suggests.
2. Spray a fine mist on plants as often as needed, "usually daily the first week, then weekly, and, if it holds out, then monthly."

Yield: About 1 gallon of preventive oil spray

Note: Andy is picky about the types of oil he will use in the garden. Plant-based oils, such as castor oil or coconut oil, are his favorites, but he is also fond of fish oils, which have minerals that can help strengthen plants against disease. Because it contains peppermint oil (which acts as an insect repellent), he likes to use Dr. Bronner's peppermint soap when mixing any garden spray with a liquid soap.

Variation: Because it's a cheap, easy, and effective alternative, many gardeners prefer plain old salad oil for disease prevention, says Marion Hess, special contributor for Prodigy's on-line gardening newsletter, *Prodigy Gardens Newsletter*. "You mix 1 teaspoon of a light salad oil, like canola or safflower, and 1 teaspoon of liquid soap in 1 gallon of water. It seems to prevent disease."

Even when they're made with vegetable oil instead of petroleum oil, oil sprays can injure your plants if you don't apply them properly. Avoid using an oil spray when temperatures are expected to go above 85°F or below freezing. It's always best to test an oil spray on a few leaves and then wait and watch for a few days before dousing an entire plant.

Fire-Away Rust Removal

If you're fond of old-fashioned hollyhocks, odds are that you're familiar with rust, the ugly orange fungus that can quickly disfigure an entire garden. "Even if you stayed on it every single day with a chemical, you would not get all of the spores," says Mary Lou Heard, owner of Heard's Country Gardens in Westminster, California. So she devised the "fire method." She just makes a tiny fire beneath the hollyhock (with safety precautions!) to kill spores. It works for roses and snapdragons, too.

Ingredients and Supplies

¼ cup shredded paper or paper scraps

Matches

Jug of water and/or fire extinguisher

Directions

1. First, remember that you are lighting a fire; although it's small, use precautions. Have a jug of water or a fire extinguisher nearby. Make sure that there is no dry material nearby that could catch a flame and be sure to completely extinguish any remaining sparks.

2. Begin by placing a thin layer of the paper at the base of the plant. "You make a little circle of fire around the stem," Mary Lou says. She explains that the fire makes an instant flash of heat in a full circle around the base of the plant. Mary Lou emphasizes that you want to make sure that the area of heat extends to the outermost leaf, however far away that farthest leaf is. That way, you can be sure that you're hitting all the rust spores.
3. Light the fire. Expect a quick flame for 5 to 10 seconds. It should extinguish on its own; if not, use the water to douse it. You may lose some lower leaves in the process, Mary Lou cautions. But she adds, "When the plant recovers from this little bitty heat, it comes back so gorgeous."

Note: If more than one plant shows symptoms of rust, repeat the process individually, for each plant. In 2 weeks, check to be sure that the plant is clean. If there are any diseased leaves, remove them. If the fungus reappears, treat that plant again. Mary Lou says she's never had any problems past that point.

Deter Disease with Disinfectant Dips for Tools

Clean your tools! You've heard that advice before, but now it's time to take it seriously. Using bleach or another disinfectant for tools is a must, says Dr. Cheryl Smith, a specialist in plant health with the University of New Hampshire Cooperative Extension. "If you're going to do pruning or any type of cutting, cut diseased areas of a plant last, and make sure that cutting tools, even scissors, get thoroughly cleaned prior to next use," Cheryl says. Otherwise, an isolated problem could become a full-scale plague.

Ingredients and Supplies

1½ cups household bleach
1 gallon water
Clean bucket
New steel wool pad
Motor oil or other oil used to condition tools

Directions

1. Mix the bleach and water to produce a 10 percent solution. This works fine for most cleaning.
2. Dip tools in the disinfectant after each use. For plants or trees that are already suffering symptoms, dip tools as you go along, cautions landscape consultant Mark Whitelaw. "If you are pruning severely diseased shrubs, or shrubs with highly infectious diseases, I recommend dipping the 'business end' of the pruners between making each cut."
3. After disinfecting, your tools need tender loving care to prevent discoloration or corrosion. Rinse thoroughly, then rub them lightly with a clean steel wool pad.
4. Sharpen the edges if you'd like, and oil the tools before storing them for the next outing.

Yield: About 1 gallon of tool-disinfecting dip

Variation: To destroy fire blight bacteria that afflicts apple and crabapple trees, use 3 cups of bleach in 1 gallon of water (a 20 percent solution), says Dr. H. Arthur Lamey, a plant pathologist with the North Dakota State University Extension Service in Fargo. Or you may use pine cleaner at full strength, he says; just be sure that the label lists 19.9 percent pine oil.

WASH UP

Don't forget to clean your shovel, hand tools, gloves, and even gardening shoes to prevent diseases from spreading, especially if you suspect a soil-borne disease. After you are finished working in the garden, wash your gloves and shoe soles in warm, soapy water and hang them out to dry.

CUT OUT DISEASE PROBLEMS WITH PROPER PRUNING

To prevent diseases on fruit and other trees, start with sharp shears, says landscape consultant Mark Whitelaw. "Clean cuts reduce the likelihood of rot and disease." Never leave a stump or stub. Cut limbs close to, but not flush with, the trunk—where the branch and branch collar (swollen area) meet. Prune so that branches grow outward; inward growth reduces air circulation, which helps diseases grow. Prune when leaves are dry.

FOILED AGAIN

As a shimmery mulch, aluminum foil can help foil viruses that afflict your vegetables, says Dr. Frank Killebrew, extension plant pathologist at Mississippi State University. And if you wrap it around plant stems, foil can also deter fungal diseases.

Ingredients and Supplies

Aluminum foil or other light-reflective material

Directions

1. For a mulch, spread a 30-inch-wide light-reflective material on the soil surrounding squash or tomatoes, Dr. Killebrew suggests. The shimmer scares away aphids and thrips, which carry disfiguring, crop-reducing viruses.
2. To deter southern blight on tomatoes and peppers, wrap aluminum foil around plant stems, from 2 inches below the soil surface to 2 inches above the soil surface. The foil serves as a physical barrier against the fungus.

Herbal Soap Spray

Keeping plants clean and disease-free is the backbone of Donna Carrier's job as owner of Organic Plant Care, an interior landscaping company based in East Swanzey, New Hampshire. Soap sprays are a crucial part of her strictly organic regimen, but they don't have to smell bad to work, she says. Donna concocted her own soap spray that's scented with fragrant herbs.

Continued →

Ingredients and Supplies

1 cup wormwood or tansy

1 cup lavender

1 cup sage

1-quart heat-resistant canning jar

2 cups water

1 teaspoon liquid, nondetergent soap, like castile soap or Murphy's Oil Soap

Pump spray bottle

Directions

1. Place the wormwood or tansy, lavender, and sage in the canning jar and fill the jar with boiling water.
2. Let the mix sit until it cools to room temperature. Then drain off and reserve the liquid.
3. Combine ⅛ cup of the herbal liquid with 2 cups water and 1 teaspoon liquid nondetergent soap.
4. Fill the pump spray bottle and spray the mixture on plants. Repeat once a month.

Yield: About 2 cups of herbal soap spray

Note: If your plants are very dirty or dusty, saturate a cotton cloth with the liquid and wipe the leaves clean.

Soapy Indoor Plant Spray

For indoor plants that are exposed to pollutants from heaters or stoves, a cleaning spray can boost health and deter diseases, says Donna Carrier, owner of Organic Plant Care, East Swanzey, New Hampshire. This gentle spray cleans dust and dirt from plants and does not pose any risks to plants or animals, she adds. You can use it in your outdoor garden, too.

Ingredients and Supplies

1 tablespoon liquid, nondetergent soap

1 tablespoon liquid seaweed (optional)

1 quart lukewarm water

Pump spray bottle

Clean cloth

Directions

1. Mix soap, seaweed, and water together in the spray bottle.
2. Spray plants liberally and wipe off excess moisture with a clean cloth. Use monthly.

Yield: About 1 quart of soapy plant spray

Plant Mixing Plan

To save cucumbers and squash from one of their greatest enemies—bacterial wilt—try companion planting, suggests Dennis Glowniak, president of the California Organic Garden Club. Dennis says you can't beat this combination of tansy and radishes for a healthy summer-long feast of cucumbers and squash.

Like many bacterial diseases, wilt is carried by an insect pest. In this case, it's the cucumber beetle, which injects the wilt disease as it feeds. In this planting plan, the pungent aroma of tansy confuses and repels the beetles, while the radishes lure them away from the vine crops.

Ingredients and Supplies

Squash or cucumber transplants

Radish seeds

Tansy plants

Directions

1. Plant the squash or cucumber transplants in your garden, and tuck radish seeds into the soil in a circle around each transplant. The radishes should pop up within a day or two.
2. Check the radishes daily for cucumber beetles and squish any that you find. If you're squeamish about squishing them, drop the beetles into a jar or bag and throw it into the trash.
3. Plant the tansy the same day you plant your vegetable transplants. Tansy can be invasive, so set it in a plastic pot with the bottom cut out and set the plant in the soil, pot and all, to contain it. If you plant tansy directly into the soil, check it regularly and pull up any underground shoots that wander away from the planting area. Plant a 4-inch clump of tansy for every 2 vegetable plants. Anecdotal evidence suggests that the tansy encourages overall healthy growth in cucumbers, Dennis says.
4. Divide unpotted tansy with a shovel at least annually. "You don't walk away from tansy," Dennis warns.

ANOTHER FRIENDLY MIX

Some herbs have a reputation for helping their neighbors fight off disease. "Try basil, for tomatoes," for instance, Dennis Glowniak recommends. "People think of basil and tomato as going well together in sauces, but actually a number of tests have shown that when they're planted together, both plants are more vigorous." Dennis explains that a vigorous plant repels diseases and insects more easily than one that's unthrifty. To give your tomatoes the benefits of basil (and vice versa), simply plant one basil plant inside each tomato cage, on the sunny side.

Keep 'Em Moving

To give your vegetable plants an added edge against diseases, enter them in a witness relocation program of sorts. That is, move them around each season so that the diseases are less likely to find them. If you always plant in the same spot, "it's inevitable

that you're going to build up disease-causing microbes in the soil," says Dr. Frank Killebrew, extension plant pathologist at Mississippi State University. "Sooner or later, you're going to get zapped."

Ingredients and Supplies

Notebook (for keeping garden records)

Chart (for reference)

Disease-resistant vegetable seeds or plants

Directions

1. "Crop rotation does require some record keeping," Dr. Killebrew says. If you've kept a garden diary in the past few years, all the better. If not, now's the time to start. Begin by making a record of what you grow where.
2. Rotate your crops as best you can, for a minimum of 3 years. If you have a small garden, you may not be able to rotate crops effectively. In that case, consider moving the location of your garden every few years.

Note: For an easy rotation, group members of the same plant family together so that you can move them together. If you have plenty of space, split family members apart to confuse insects in addition to disrupting diseases. Then make sure that you rotate all of the individuals to new locations where no members of the same family have grown in the previous 2 years. Ideally, you should move crops to new ground after just 1 season, but certainly after 2 seasons, Dr. Killebrew says.

MORE DISEASE-STOPPING METHODS

Crop rotation goes a long way toward reducing disease (and insect) problems, but like any other garden technique, it's not a complete solution. "Crop rotation in itself does not mean that you've walked away from the problem," Dr. Frank Killebrew says. You still need to take other steps, like mulching and planting disease-resistant vegetable varieties. Mulch helps tomatoes and other vegetables avoid being splashed by rain or irrigation water—on its own, the water is harmless, but it gives diseases a medium for spreading. Planting disease-resistant varieties is a great way to combat wilts and other diseases which are willing to wait in the soil. Fusarium wilt, for instance, will not disappear from the soil just because you've moved its favorite meal away for a few years.

Disease Glossary

Acervulus A shallow, saucer-shaped mass of hyphae with a depression in the center that bears conidiophores—stalk-like filaments that have conidia (asexual spores) at the tips. Spores are released when the acervulus grows and ruptures cells of the host plant. Plural is *acervuli*.

Alternate host One of two plants upon which a parasitic fungus must live.

Anthracnose A disease characterized by lesions that show on the epidermis. Caused by fungi that produce asexual spores in acervuli.

Ascomycetes A fungal group characterized by a membranous sac, or ascus, in which the cells divide to form ascospores. Yeasts, molds, and mildews are ascomycetes. Ascospores are sexual.

Bacteria One-celled microorganisms that reproduce by division. Bacteria are dependent on either dead or living organic matter for food.

Bacteriophage A virus-like organism that destroys bacteria.

Basidiomycetes A group of fungi characterized by mycelium with cross walls and the production of sexual spores on club-shaped filaments called basidia. Rusts, smuts, and mushrooms are basidiomycetes.

Blasting Failure to produce fruit or seeds.

Blight General description of diseases that cause sudden leaf, flower, or stem death.

Blotch A superficial spot or necrotic area.

Canker A diseased or dying area on a stem. Most commonly applied to woody plants.

Carrier A plant or animal bearing an infectious disease agent without showing symptoms. Carriers can transmit the disease to other organisms. Most bear the disease agent internally, although the term can be used when the agent is carried externally.

Causal organism The organism responsible for causing a disease.

Certified seed Seed monitored to ensure varietal purity and freedom from disease organisms.

Chlamydospore An asexual spore formed by a mycelial cell. Thick-walled, chlamydospores are resting spores that can remain dormant until conditions are correct for development.

Chlorosis Yellowing caused by partial failure of chlorophyll development. Symptomatic of many diseases.

Coalesce To grow together to form one spot or splotch.

Conidia Asexual spores formed at the tips of conidiophores. Produced most numerously during the height of the growing season, conidia are wind- or rain-borne.

Conidiophore Hyphae on which conidia are produced.

Damping-off Used to describe the death of seedlings, emerged or not, caused by a number of organisms.

Defoliate To cause most leaves on a plant to die and drop.

Dieback Progressive death of branches or stems from the tip backwards toward the main stem or trunk.

Continued ➔

Enzyme A chemical produced by cells which brings about changes in processes such as ripening or digestion. Some pathogenic bacteria produce enzymes that damage host plants.

Epidermis The outermost layer of cells of a plant part.

Epinasty An abnormal growth pattern of leaves caused by rapid growth of cells on the upper surface, resulting in a downward cupping of the leaf.

Escape Applied to plants that are not resistant to a particular pathogen but do not acquire it.

Exudate Any substance produced within a plant that is then released or discharged through natural openings or injuries.

Facultative parasite An organism that can grow on either living or dead organic matter.

Fasciation Plant distortion caused by injury or infection resulting in flattened or curved shoots. Stems may look fused.

Flagellum A whiplike filament of a cell enabling it to swim through liquids.

Fruiting body A plant that lacks chlorophyll and is dependent upon either dead or living organic matter for food supplies. Fungi reproduce by both sexual and asexual spores and are composed of a body of filaments called hyphae that form branched systems called mycelia.

Gall A localized swelling composed of unorganized cells. Caused by bacteria, fungi, or insects.

Gamete A mature sex cell.

Girdle A lesion that encircles the stem or root, causing death.

Haustorium A specialized fungal hypha that penetrates the cells of a host plant and absorbs food from them.

Host A plant infected or parasitized by a pathogen.

Hyperplasia Abnormal increase organic tissue in formation of galls and tumors.

Hyphae Threads or filaments of a fungal mycelium or body.

Lesion A spot or area of diseased tissue.

Mildew A fungus that grows on the surface of plant parts.

Mold A fungus that produces a woolly growth on the surface of plant parts.

Mosaic A disease caused by a virus, characterized by mottled patterns of yellow and green on the leaves.

Mycelium The vegetative body of a fungus, composed of many hyphae.

Necrotic Dead. (Necrosis is death.)

Nematode Nonsegmented, microscopic roundworms that live in soil, water, plants, animals, and dead organic matter. Some nematodes are plant parasites.

Nodule A lump or knot.

Obligate parasite A parasite that can live only on living matter.

Parasite An organism that obtains its nutrients from a secondary organism.

Pathogen An organism capable of causing disease in other organisms.

Penetration peg A strong hypha anchored to the host surface with a sticky substance. Produced in order to bore into a host.

Perfect stage The period of a fungal life cycle when spores are produced sexually.

Phloem The vessels in the plant that carry dissolved sugars from leaves to the rest of the plant. One of the two vessels in the vascular bundle.

Phycomycetes One group of fungi. Characterized by sexual reproduction and few cross walls in the hyphae.

Primary infection The first infection by a fungus after a resting period.

Pustule A blisterlike structure.

Pycnidium A flask-shaped, fruiting body of a fungus that contains asexual spores. Usually located near the surface of the host.

Pycnium The flask-shaped, fruiting body of a rust fungus that contains pycniospores. These spores are unisexual and are usually fertilized by insects feeding on the nectar produced in the pycnium.

Resistance Ability of a plant to remain relatively healthy despite infection by a pathogen. Resistance is an inborn quality and is not caused by environmental factors.

Resting spore A spore that can remain for long periods of time before germinating. Most resting spores are very thick-walled.

Ring spot Symptomatic of some diseases. Ring spots are brownish yellow on the margin and green in the center.

Rogue To remove a plant. Plants infected with some diseases are normally rogued to prevent the spread of the disease.

Rosette Formation of short-stalked leaves that radiate from a central stem. Some diseases produce an unnatural rosette in their hosts.

Russet A corky, roughened area on the skin surface. Russeting can be caused by pathogens, insects, or cultural techniques.

Rust The disease caused by a rust fungus, or the fungus itself. Rusts may have one or more hosts through their life cycles and, in some cases, have as many as five types of spores.

Saprophyte An organism that feeds on dead organic matter.

Scab A disease that is characterized by rough, scaly tissue on the skin surface.

Sclerotium A resting mass of fungal hyphae that does not contain spores but that is capable of becoming dormant and remaining so for many years before resuming growth.

Scorch A burning of tissue caused by a pathogen or by environmental conditions.

Secondary infection A disease caused by infectious material following a primary infection or produced by reproductive material that has not undergone a resting period.

Shothole A disease symptom in which small round holes die and drop out of leaves.

Sign Any visible portion of a pathogen. Signs can include mycelia, spores, fruiting bodies, or even a mass of bacteria.

Smut A disease caused by a smut fungus, or the fungus itself. Smuts are characterized by the formation of dark masses of resting spores.

Sporangium A fungal fruiting body that produces asexual spores.

Spore A single cell or multicelled reproductive unit. Fungi produce sexual and asexual spores. The resting structures of some bacteria are also called spores.

Strain Synonym for race when describing plant pathogens. A strain, or race, is a subgroup within a species that differs in host range or effect from other members of the species.

Summer spore A spore that proliferates during the best growing conditions and that does not rest between release and germination.

Susceptible Without inherent resistance to a pathogen.

Systemic Applied to a pathogen or chemical that travels throughout the plant body. Many systemics travel through the vascular system.

Thallus The vegetative body of a thallophyte, a simple plant, including fungi, algae, bacteria, slime molds, and lichens.

Tolerant Capable of sustaining an infection by a pathogen, or of enduring environmental stress or injury without much damage.

Toxin A poison.

Vascular Applied to the vessels in the plant that carry water or nutrients. Respectively, these are the xylem and phloem vessels.

Vector An organism or agent that transmits diseases. Many insects are vectors of plant diseases.

Vein-banding A symptom of some viral diseases in which regions along the veins are a darker green color than regions between veins.

Virulent Strongly capable of producing disease.

Virus An obligate parasite composed of genetic materials and protein that is capable of reproducing within living materials.

Wilt Drooping plant tissue as a consequence of insufficient water supply. Some diseases cause wilt by plugging the vascular system.

Xylem The vessels that carry water in the plant.

Yellows Disease that causes abnormal yellowing of leaves and stems.

Zoospore A spore that swims.
